PREFACE

Each of the first fourteen editions of the *Extra Pharmacopœia* was published in one volume and it was in 1912 that the first edition in two volumes was published. It was realised at that time by the author that the ever-increasing amount of information on compounds and preparations used by the physician and the pharmacist was too great to be issued conveniently in one volume. The second volume of the Fifteenth Edition contained 370 pages and the matter collected and considered suitable for recording has increased steadily during the last thirty years; this second volume of the Twenty-second Edition contains 1217 pages. Since the publication of the second volume of the Twenty-first Edition in October 1938, despite the conditions prevailing during a world war, much new information has been gathered from the continued progress of research in medicine and chemistry and, although the general scope of the volume has undergone little change, substantial modifications of the matter in the previous edition have been made and a considerable proportion of new matter has been added. This second volume deals with the numerous subjects ancillary to those dealt with in the first volume and will continue to provide the reader of the *Extra Pharmacopœia* with up-to-date information on such matters as the methods by which the purity of medicinal substances is maintained, the analysis and composition of some of the principal foods, the application of chemistry as an aid to clinical diagnosis and the bacteriology of certain diseases. It includes also matter on numerous other subjects with which physicians, chemists and pharmacists should be acquainted in the ever-widening sphere of studies for the improvement of health, the relief of pain and the cure of disease.

Analytical Addenda

The requirements of the British Pharmacopœia, 1932, and of the British Pharmaceutical Codex, 1934, are summarised in this section and special attention has been given to comments and abstracts from published papers which have a bearing on these official standards. All the modifications and changes in the addenda to the *B.P.* issued since 1938 have been incorporated, as well as the new matter and amendments in the six supplements to the *B.P.C.* The assays and standards of the *United States Pharmacopœia* and the *American National Formulary* have been revised in accordance with the *U.S.P. XII* and the *N.F. VII* which became official on November 1st, 1942, and the standards required by the most recent issues available of other national pharmacopœia are also included. Comparisons of the standards for the same substances in these different authorities show clearly the divergencies of opinion which exist concerning individual

methods and emphasize the need for closer co-operation between the responsible parties of the various countries. Valuable information to analysts is provided by the inclusion of assay processes for many medicinal substances in the form of tablets from the *U.S.P.* and the *N.F.* In the 21st Edition reference was made to the Second Report of the International Commission dealing with the analysis of proprietaries and to the attention it gave to the standardisation of substances in tablets, but so far no addendum to the *B.P.* or supplement to the *B.P.C.* has been published containing monographs comparable with those of the United States authorities. Similarly, references are made to valuable work done in America by the Association of Official Agricultural Chemists, to the specifications for numerous materials produced by the British Standards Institution and to the agreed methods produced by Sub-Committees set up by the Society of Public Analysts. As in previous editions, references to or abstracts of papers of direct value which have appeared in the various pharmaceutical, medical and chemical publications have been included.

The following are a few of the important subjects dealt with in this section:—

ACIDUM ACETYSALICYLICUM. In the 21st Edition reference was made to the method of the A.O.A.C. for the determination of aspirin in tablets and to processes recommended for determining free salicylic and acetic acids, but there were no officially standardised tablets. Suggestions have been made to include standards for tablets of all the commoner medicinal substances in either the *B.P.* or the *B.P.C.*, but none have been issued up to the present. The *U.S.P. XII* and the *N.F. VII* contain many of these tablets and here we would draw attention to the *U.S.P.* monograph on aspirin tablets as an example of methods summarised in this edition which will be useful as a guide to analysts in this country until such time as the authorities here are ready to publish British standards. The *U.S.P.* does not prescribe a definite size or shape of tablet but requires the bulked tablets to contain from 95 to 105% of the labelled amount of pure $C_9H_8O_4$. In general the standards are set on the substances assayed and therefore there are no further allowances to be made for the purity of ingredients or loss in manufacture. Undue variations in results due to different methods of sampling or to varying numbers of tablets in the samples are avoided by taking 20 tablets for the assays. Evidently tablets are not necessarily manufactured from pure material, but they must contain on the average, within defined limits, a quantity of chemically pure material equivalent to the stated amount of drug present. Considerable variation in size is permitted and the rate of disintegration, shape, colour, the presence of impurities and proprietary marks have not been considered of sufficient importance to warrant control.

ACIDUM BORICUM. The standards for surgical dressings are included and it will be noted that owing to the need for economy

in the use of boric acid the strengths of official preparations have been reduced—Boric Lint *B.P.C.* from 40 to 5% and Boric Ointment *B.P.* from 10 to 1%. The simple methods used for determining boric acid in a paraffin base may require slight modification when dealing with a wool wax base and a much smaller percentage of boric acid.

ACIDUM HYDROCYANICUM. Reference is made to the specifications for cyanide insecticides, and here is added the first of a number of abstracts included in this section from leaflets issued by the Department of Scientific and Industrial Research on Methods for the Detection of Toxic Gases in Industry which can be obtained from His Majesty's Stationery Office. Hydrocyanic acid is widely used as a fumigant and its vapour may also be met with in dangerous concentrations in certain industries.

ACIDUM MANDELICUM. The standards of the *B.P.* and *U.S.P.* are compared and the *U.S.P.* standard is included for the calcium salt which is sometimes preferred owing to its freedom from unpleasant taste when mandelic acid is administered in the treatment of infections of the urinary tract.

ACONITUM. This drug has been dropped from the *U.S.P.* and transferred to the *N.F. VII* so that the controversy concerning standardisation is not now so acute. The American drug is still standardised biologically, but in Great Britain a new chemical assay has been devised by a sub-committee appointed by the Society of Public Analysts and this method which is outlined will be sufficient to meet the needs of analysts who have to standardise galenicals or to determine the alkaloids of aconite under the Pharmacy and Poisons Act, 1933, or the Pharmacy and Medicines Act, 1941.

ALCOHOL TRIBROMOETHYLICUM. Bromethol is the solution of tribromoethyl alcohol in amylene hydrate used as a basal anæsthetic for rectal administration and the standards of the *B.P.* and *U.S.P.* for both substances are given. It is difficult to understand why these two standards should differ so appreciably; some of the tests for purity for both tribromoethanol and amylene hydrate may produce the desired results and both assays for tribromoethanol may be considered dependable, but why in two English-speaking countries should they be so differently expressed? The *B.P.* requires 99% of tribromoethanol and the *U.S.P.* only 98% and the specific gravities and boiling ranges are not comparable. Incidentally, analysts who are accustomed to checking official boiling ranges have to use a more practicable procedure than that officially prescribed.

ALCOHOLIA LANÆ. This is the *B.P.* Latin name for the mixture of wool alcohols prepared by the saponification of wool fat which is a non-proprietary emulsifying agent now used in place of paraffin bases for making many official ointments. In some cases absorption of the active ingredient from the hydrous base is more rapid and in war-time a great economy in paraffins

is effected. The standard required is included and the official digitonin assay is outlined.

ALUMINIUM. In this section the two new *B.P.* kaolins and the standards set for limits of particle size which are determined by finding the specific gravities of suspensions prepared under controlled conditions are referred to. Light kaolin is to be used for internal administration and the heavy variety for making kaolin poultice. For further particulars regarding the control of these two substances the recent paper by Page (*Quart. J. Pharm.*, 1943, 1) should be consulted. Bentonite, the American native aluminium silicate, is also referred to.

ARGENTI PROTEINAS. The nomenclature of the two silver proteates of the *U.S.P.* and that of the corresponding substances in the *B.P.* and *B.P.C.* have not reduced the confusion between therapeutic activity and silver content; adjectives indicating activity are out of place when associated with chemical names. This confusion has evidently spread to the compilers of the *U.S.P. XII* and the amusing error made by including the same test for distinction between the two substances in both monographs needs early correction.

BARBITONUM. The standards for several new barbiturates of the *B.P.*, *B.P.C.*, and *U.S.P.* are described, including those for Hexabarbitone, Soluble Hexabarbitone, Phemitone and Soluble Phenytoin. Attention is given to the several standardised tablets of the *U.S.P.* The lack of uniform nomenclature for all these important hypnotics is a regrettable feature and provides another example of the need for that co-operation which was stressed in the second report of the International Commission. "Phenobarbitonum Solubile" *B.P.* is required to contain not less than 95% of $C_{12}H_{11}O_3N_2Na$, whereas "Phenobarbitalum Sodicum" *U.S.P.* may contain 7% of moisture and the dried substance from 89 to 91.5% of $C_{12}H_{11}N_2O_3$.

BELLADONNA. Reference is made to the admission to the *B.P.* of Indian belladonna leaf and root derived from *Atropa acuminata* (Royle), syn. *Atropa lutescens* (Jacquem) which may now be used for the manufacture of galenicals. The assay is altered so as to eliminate volatile bases obtained, but there does not appear to be any agreement as to the best way of attaining this, and the standards do not seem to be very suitable for shipments exported to Great Britain.

CAFFEINA. In this section standards and assay processes for caffeine, theobromine and theophylline and several compounds of these three ureides are outlined, including theophylline ethylenediamine and the tablets of the *U.S.P.* and *N.F.* In America the process of Self and Rankin appears to give erratic results and the *U.S.P.* has adopted the silver method of Stevens and Wilson, which undoubtedly gives low results, in preference to Warren's useful modification of Reimer's process.

CARBO. The standards of the *B.P.C.* and *U.S.P.* for medicinal charcoal are compared, but there is still no pharmacopœial

specification for this important material. Attached to this section are useful short references to the leaflets issued by the Department of Scientific and Industrial Research on the detection of carbon monoxide and phosgene which may occur in dangerous proportions in certain industries.

CINCHONA. In the section on Cinchona is included a tabulated summary of the compositions and standards for all the official quinine salts and the standards for other cinchona alkaloids of the *B.P.*, *B.P.C.* and several national pharmacopœias. Recent orders under the Defence Regulations control the sale and use of cinchona, cinchona products and synthetic substitutes. The principal synthetic substitutes are mepacrine hydrochloride and methanesulphonate and pamaquin, which are used for their action upon malarial parasites; their official standards are summarised in comparison with the corresponding American substances, quinacrine hydrochloride and pamaquine naphthoate.

DERRIS. The variation in activity and rotenone content of different supplies of this important insecticide continues to receive attention from experts and variable results are frequently obtained in different laboratories. The work of Coombes, Martin and Harper is referred to and a process recommended for inclusion in the *B.P.C.* and based upon a paper published by them is described.

DIGITALIS. The biological methods for the standardisation of powdered digitalis and tincture of digitalis are summarised. The reference standard of the *U.S.P.* is now equivalent in potency to the standard adopted by the League of Nations Commission, and the *U.S.P. XII* contains a standardised tablet of the leaf. Digoxin, the important glycoside obtained from the leaves of *Digitalis lanata* and which is of particular value in the treatment of auricular fibrillation, does not require biological standardisation and chemical tests for purity are now described in the *B.P.*; until August, 1945, digoxin is controlled by patents in Great Britain and Northern Ireland.

EPHEDRA. The *B.P.* standard for ephedrine monohydrate and the *B.P.C.* standard for anhydrous ephedrine are compared with that of the *U.S.P. XII* which includes both forms. Tablets of the sulphate and hydrochloride are standardised in the *U.S.P.* and *N.F.* respectively; summaries are also given of the new *B.P.C.* standards for amphetamine and amphetamine sulphate which in their local effects resemble adrenaline and ephedrine.

ERGOT. Years have passed since the classical experiments by Chassor Moir which resulted in ergometrine being accepted as the most important constituent of ergot. To-day in the 6th addendum to the *B.P.* this drug and its official preparations are standardised not only on their total alkaloid but also on their ergometrine content. The old standard of 0.05% of total alkaloid for ergot is replaced by one requiring 0.2% of total alkaloid of which not less than 15% is water-soluble alkaloid calculated as ergometrine and the drug is assayed by the well-tried

method of Hampshire and Page. Some chemists are of the opinion that the determination of water-soluble alkaloids is not a measure of the ergometrine content and that the percentage of true ergometrine may be below 10% of the total alkaloid. A good ergot usually contains over 0.25% of alkaloids and often 20% of this is water-soluble. The *U.S.P. XII* still uses the pedigree Leghorn cock method with ergotoxine ethanesulphonate as control.

FERRUM. This section contains many useful references to iron determinations in medicinal preparations with abstracts of improved procedures for several compounds and for the determination of small amounts of impurities such as lead and copper.

GOSSYPIUM. The 1st Supplement to the *B.P.C.* contains new surgical wound dressings and a summary of its requirements is given under this heading, together with references to alternative specifications for battiste and jaconet and the new waterproofed rayon which is used in the application of hypochlorite solution for the treatment of burns.

IPECACUANHA. The official standards have again been reduced to admit the poorer type of Minas root to be used for powdered ipecacuanha and other galenicals. The effect of this remains to be seen; with the high prices prevailing there may be a demand for still poorer material and a further request for a lower standard.

MAGNESII TRISILICAS. This substance has found a place in the treatment of peptic ulcers, but in some quarters doubt is expressed concerning its efficacy. Some details are given of the *B.P.* and *B.P.C.* requirements and reference is made to the *U.S.P.* tablets which are standardised for limit of free alkali, acid-consuming capacity and adsorptive power.

ESTRADIOL. Following the introduction of specific sex hormones this section has been completely rewritten. Stilbæstrol of the *B.P.* and the substances of the *U.S.P.* are compared, together with the several hormones of the 3rd Supplement to the *B.P.C.*, including œstradiol, œstradiol benzoate, œstrone, œstrone benzoate, progesterone, testosterone and testosterone propionate. Possibly by the time the next edition is published some more useful therapeutic applications may have been discovered for some of these mysterious medicaments.

SACCHARIN. In a time of sugar shortage this substance is an important commodity and the standards of the *B.P.C.* and *B.P.* for saccharin and soluble saccharin respectively are compared with those of the *U.S.P.* for saccharin and "saccharinum sodicum". Abstracts of newer methods for the determination of saccharin and dulcin in foodstuffs and tablets are also given.

SULPHANILAMIDUM. Following the discovery of the value of the sulphonamide group of chemicals in the treatment of streptococcal and pneumococcal infections several new specifications have been included in the national pharmacopœias, among them being sulphanilamide, sulphapyridine and sulphathiazole, which

are also included as tablets in the *U.S.P. XII*. The assays are compared and several abstracts of papers on recent investigations have been added.

VITAMINS. Ascorbic, nicotinic and pantothenic acids, aneurine hydrochloride, riboflavin and other substances related to the naturally occurring food factors are described in the later sections dealing with nutrition and vitamins.

Proprietary Medicines

The section gives a brief historical review of the various efforts, made over a period of years, to secure more adequate legislative control over the advertising and distribution of proprietary medicines. Since the previous edition was published the passing of the Pharmacy and Medicines Act 1941 has modified many of the previously existing practices. The Act, so far as it concerns proprietary medicines, secures two main objects; it repeals the Medicine Stamp Duties and it imposes certain restrictions on the sale of medicines. Medicines are no longer subject to stamp duty but all articles sold with a recommendation as to their therapeutic value in the treatment of human ailments must bear a quantitative disclosure of composition. The Act endeavours to maintain, as far as possible, the position which existed when "destamping" had become the almost invariable rule. In addition, the advertising of remedies for the treatment of certain diseases is prohibited. Section 12 creates a group of "authorised persons" permitted to sell recommended medicines and limits the class of medicines which may be sold by drug sellers not within one of the named classes. Definite rules are laid down for the method to be adopted in naming the ingredients of a preparation and although the compositions of a large number of preparations have been disclosed it must not be assumed that the correct form of disclosure has been adopted by the maker in every case. Revision of labels to bring them into line with the legal requirements is still in progress and it is possible that revised forms of disclosure will be adopted from time to time as misleading names are discovered and when reprinting is undertaken by the manufacturers.

The list of proprietary medicines included has been completely revised and now contains approximately 750 of the most widely advertised remedies. The so-called ethical proprietaries have been transferred to Volume I and the list now contains only those preparations which are popularly described as "patent" medicines. The disclosure of composition has abolished the principal criterion by which ethical preparations and proprietary medicines were distinguished and for all practical purposes secret remedies are to-day non-existent. Ethical preparations which are usually included in Volume I cannot therefore be clearly distinguished from the non-ethical by reference to the amount of information available as to their composition. The division is now based upon the method of distribution, i.e., upon whether a preparation is sold to the public by advertisement and without reference to the

requirements of the individual patient or whether it is a product recommended or prescribed for use under medical supervision. In each case the name of the manufacturer, the principal claims made for the preparation and the formula or composition is taken from the label of the container or from the accompanying literature. The list may be useful to doctors who seek information concerning preparations which their patients have been in the habit of taking. It reveals an extremely interesting situation and emphasizes the need for immediate action by the responsible authorities. Although war conditions may in certain cases provide a plausible excuse, it seems unreasonable a year after the Pharmacy and Medicines Act came into force that it should be possible to purchase proprietaries for which the composition is not disclosed or is disclosed in a manner not in accordance with legal requirements. That so many useless "medicines" containing ingredients which in war-time must be imported or are required more urgently for other purposes is to many persons beyond comprehension. Furthermore, it will be interesting to see for how long unjustifiable claims are permitted to be made for preparations containing only ingredients which have no useful therapeutic effect. In many cases the effect can only be psychological and due to the extraordinary claims or to the illegal or pseudo-scientific terminology by which excipients, vehicles, flavours and colouring matters are presented as modern therapeutically active and important constituents.

Nomenclature of Organic Compounds

The basic framework of this section cannot alter, but its utility has been extended to include most of the medicinal compounds which occur in the *B.P.*, the *B.P.C.* and their addenda and supplements. From July 1st, 1942, the formula or composition for substances recommended as medicines must be disclosed on their containers or labels. If the constituents are in the *B.P.* or *B.P.C.*, the official name, abbreviation or synonym must be used. If such be not the case "the accepted scientific name or other name descriptive of the true nature of the substance, constituent or ingredient" may be used. For chemical compounds the term "accepted scientific name" referred to in the Pharmacy and Medicines Act, 1941, may be interpreted as a non-ambiguous, systematic name which would disclose to a competent chemist the chemical structure or identity of the ingredient. It is obvious that this new requirement focuses attention on the necessity for a systematic nomenclature.

Chemotherapy

This section is not limited to a consideration of only those chemicals which combat invading organisms, since the true interpretation of the word "chemotherapy" includes the action of all chemicals used in therapy and excludes no substance the therapeutic activity of which is related to its chemical structure.

The matter has been revised to include the work of the last few years and reference is made to the new theories of indirect action whereby the substance is thought to exert its effect by interfering with an essential enzyme process or an essential metabolite. The development of the sulphonamide drugs is brought up-to-date by the inclusion of the main compounds of this type in use to-day and some indication is given of the objects and aims for future research in the series. The remarkable work of the last few years resulting in a knowledge of the structure of the sterols, bile acids, cardiac glycosides, calciferol and the steroid hormones provides a striking instance of greatly differing effects produced by variation on a single theme (the cyclopentenophenanthrene skeleton). In this connection the work which led to the introduction of stilboestrol and hexoestrol into medicine and to the discovery of the first synthetic substances possessing activity similar to that of desoxycorticosterone is explained from a chemotherapeutic point of view.

Recognition of Organic Substances

The systematic scheme for the recognition of organic medicinal compounds and the table of corroborative tests remain in the same form, but have been improved by the addition of many new substances including those recently added to the *B.P.* and *B.P.C.*, among which will be found some of the newer barbiturates, anæsthetics, sulphonamides, vitamins and hormones.

Hydrogen Ion Concentration

The theoretical considerations underlying the determination of hydrogen ion concentration and the advantages and disadvantages of the various methods of determination have been retained with an extended list of applications of *pH* measurement and control. The tabulation of the *pH* of solutions of common substances has been extended to include the more important of the newer therapeutic agents.

Oxidation-Reduction Potentials and Polarographic Analysis

The section on oxidation-reduction potentials remains substantially unaltered but the recent increasing use and application of electro-oxidation and electro-reduction to analytical problems by means of current-voltage studies has led to the inclusion of a new section on Polarographic Analysis. Invented in 1925 by Heyrovsky, the polarograph is an instrument by means of which current-voltage curves may be obtained automatically and recorded photographically, the recorded curves being termed polarograms. The theoretical considerations underlying polarography are discussed, the technique of the method is described and the many applications are indicated. Inorganic analyses have been more widely studied but the method has also been applied to many problems of analyses involving organic compounds. The method is specially suitable for small concentrations and is applicable to

values of a large number of foods have been added. As in previous editions sections dealing with particular foodstuffs such as milk and milk products, flour and bread, etc., though dealt with under separate headings, are regarded as forming part of the wider subject of nutrition, while a new section on Food Substitutes has been added for the purposes of information.

MILK AND MILK PRODUCTS. The extensive section on milk has been rearranged and clarified as far as possible and a few minor additions inserted. A new monograph on cheese has been introduced and the section is followed by revised accounts of the composition and analysis of margarine and other foods, including jam and vinegar. Reference is made to the work of Edwards and Nanji on the differentiation of the various types of vinegar by analytical methods. The information on food preservatives and colouring agents is retained, but it has not been considered necessary to retain the short monographs on mould inhibition by preservation and on the so-called putrefactive bases.

FLOUR AND BREAD. The monograph on flour and bread has been re-written, particularly from a nutritional standpoint. War-time restrictions on the types of flour which may be milled have revived the controversy concerning the respective nutritional values of white and brown bread and the increased knowledge now available may have important results in post-war practice. Other starch foods have been included in this section and the effects of different forms of cooking on the nutritional value of potatoes have been summarised.

FOOD SUBSTITUTES. A useful general account of the composition and control of war-time food substitutes has been included. During the past three years public analysts have investigated the composition of new articles purporting to be food substitutes, of which some thousands have been offered to the public. Few of these possessed any intrinsic value and since the Ministry of Food took over the control of the manufacture and retail sale of these preparations only about three hundred have survived.

FOOD LEGISLATION. The principal provisions of the Food & Drugs Act, 1938, are concisely arranged for reference, together with a list of Regulations made under the Act. During the war almost all articles of food are subject to provisions of Statutory Rules & Orders issued by the Ministry of Food; the most important of these are summarised under the title "Alterations in the Composition of Food due to War." Since going to press with this section of the text a further Order has been issued (S.R. & O., 1943, No. 1553) regulating the labelling and advertising of foods, with particular reference to the quantitative disclosure of the mineral and vitamin contents of foods and the restriction of claims or suggestions in advertisements regarding the presence of these substances.

Vitamins

Research work on the vitamins shows no signs of slackening; indeed, it would appear to have been stimulated by war-time

needs. It is much to be deplored that the valuable and painstaking work of scientific and clinical investigators should have given rise to one of the worst examples of commercial exploitation ever perpetrated on the public. The layman has been made aware, through various channels of information, that authentic claims may justifiably be made for the prophylactic and curative properties of a number of the vitamins. What he does not always appreciate is that these clinical applications refer only to the use of individual vitamins in certain specific conditions and that an adequate scheme of dosage under medical supervision is essential to their successful employment. He is thus easily persuaded to waste his money on one or other of the innumerable vitamin preparations with which the market has been flooded in recent years the majority of which, in spite of the scientific appearance of their formulæ and the apparent plausibility of their claims, have little or no therapeutic value. Since the last edition of this volume the chemical composition of a number of the vitamins has been determined and some of them (or their therapeutic equivalents) have been synthesised including vitamins B₁, B₂, C, E and K. For the convenience of readers the vitamin classification is still adhered to, the chemical names of the substances—e.g., aneurine hydrochloride, riboflavin, ascorbic acid, tocopheryl acetate and menaphthone—appearing as subsidiary headings. Many of these substances have been given official recognition in one or other of the *B.P. Addenda* and in the *U.S.P. XII* and information from these publications has been incorporated in the appropriate monographs. The vitamin B complex has been the subject of intensive research work during the past few years and in addition to aneurine hydrochloride and riboflavin there are now available commercially: nicotinic acid and its amide (both *B.P.* substances), pyridoxine (vitamin B₆) and pantothenic acid (usually supplied as calcium pantothenate). Abstracts from the literature dealing with the chemistry, the determination and, in the case of the two last-mentioned, the clinical work on these substances are included. Menaphthone (known in America as menadione) is the synthetic therapeutic equivalent of vitamin K; methods both for the biological and chemical determinations are given. Both menaphthone and acetomenaphthone (the salt used for oral administration) are now *B.P.* The existence of a "permeability vitamin," vitamin P, would appear to have been finally confirmed quite recently by an American worker (R. H. Rigby) who has produced from orange hesperidin a permanently water-soluble substance known as methyl chalcone which affords protection against capillary fragility. The section on vitamins concludes with a new table, especially compiled for this work, giving the average vitamin contents (A, B₁, B₂, C and D) of a very wide range of foodstuffs and the use of this table in conjunction with the table giving the composition and caloric values of foods should prove of assistance in the drawing up of a balanced diet to meet the requirements either of health or disease.

Sterilisation

As a result of recent research work, processes for the sterilisation of solutions for parenteral injection have been revised in the 4th Addendum to the *B.P.* A new process of sterilising at a temperature of 98° to 100°C with the aid of a bactericide has been introduced which greatly facilitates the preparation of sterile solutions of many substances which are too unstable to withstand autoclaving. The process of tyndallisation has been deleted as untrustworthy for the usual type of solution for parenteral injection though it is quite suitable for nutrient media. Much attention has been given during recent years to methods for the sterilisation of surgical dressings, following a report of a heavy tetanus infection in cellulose wadding dressings and of the occurrence of tetanus and welchii spores in sanitary pads and even in so-called "sterile" accouchement sets. Some account of this work has been included.

Disinfectants

This section has been completely re-written and considerably extended to include many new types of disinfectants. Experience of war wounds has increased our knowledge of the use of antiseptics in wounds very considerably and an extended account of this work is given. The important developments in the use of colloidal-mists or aerosols for the sterilisation of the atmosphere, as in air-raid shelters, operating theatres and isolation wards, are included.

Radiology and Electrotherapy

The article on the use of galvanic, faradic and sinusoidal currents for the treatment of disease, which was rewritten for the twentieth edition, was largely based on the results of the treatment carried out in the electrical department of one of the big London hospitals. The article has since been revised and brought up to date and in the present edition there is added an account of the method of treating schizophrenia and some other types of mental illness by means of electrically induced convulsions as originally described by Cerletti and Bini. This method is now employed in several mental hospitals and to a large extent has replaced the use of leptazol and other convulsant drugs, since by its means the dose can be regulated more accurately, fits induced with more conformity, and the extremely unpleasant effects of the intravenous injection of large doses of leptazol and other drugs avoided. Revision of the section on radiology has resulted in the deletion of some general matter on the properties of radium, and in diagnostic radiology the new official nomenclature has been applied to the drugs used. Reference is made to the recent advances in the adoption of mass radiography of the chest, both for the services and the civilian population.

Bacteriological and Clinical Notes

The information in this section is, as in former editions, largely

complementary to the information concerning antitoxins, sera, vaccines, etc., given in Volume I. In addition, this section contains details of the ætiology and symptomatology of many parasitic diseases. The whole of the text has been carefully revised and in many instances entirely rewritten with a view to increasing its value to bacteriologists, physicians, pharmacists and others interested in the practical application of laboratory methods as aids to diagnosis. The particulars concerning the morphology, cultural characteristics, and biochemical reactions of the common pathogenic bacteria, have been amplified, particularly in the case of the salmonella group, the typhoid-paratyphoid group and the streptococci. Details of the composition of several new culture media, which assist the rapid isolation of bacteria, e.g., the dysentery and paratyphoid groups, have been added. The recognition of several outbreaks of trichiniasis in Great Britain in recent years seems to warrant the inclusion of an account of the clinical features of this disease, which it would seem may often pass undiagnosed if unsuspected. Notes have been added on the clinical features of cysticercosis in view of the increased prevalence of epilepsy from this cause among men returning from service in the East. The sections relating to beri-beri and pellagra have been omitted, since these diseases are now fully recognized as resulting from deficiency of vitamin B₁ and nicotine acid respectively. Likewise, there would seem to be no useful purpose in retaining details of the numerous theories of causation and obsolete forms of treatment of cancer.

The following are some additions of special interest:—

ABORTUS FEVER. Prophylactic inoculation of cattle with a vaccine made from an attenuated strain of *Br. abortus* is now sanctioned by the Ministry of Health; the use of a vaccine made from dead organisms has not proved satisfactory. Some notes are included on the diagnosis of abortus fever in the human subject, and should be read in relation to the general section on undulant fever, of which abortus fever is the commonest variety in Great Britain.

ACNE VULGARIS. The use of penicillin in glucose broth medium inhibits the growth of staphylococci and allows a primary growth of acne bacillus to be obtained in pure culture.

ACTINOMYCOSIS. Involvement of the central nervous system is a rare complication, and pathways of spread of the infection from a primary focus are discussed.

BACTERIAL FOOD POISONING. The notes on the Gaertner group of bacteria have been rewritten, and some details of methods for the differentiation of food poisoning organisms are included. Notes have been added on staphylococcus food poisoning due to an enterotoxin formed by some species of staphylococci, which have been implicated to an increasing extent in some recent outbreaks.

BLACKWATER FEVER. The ætiology of malarial hæmoglobinuria is considered to be allied to that of the hæmoglobinuria of primary

hæmolytic anæmia and may be due to the increased liberation of an intracellular hæmolysin.

BOTULISM. The exotoxins of *Clostridium botulinus* and methods for the detection of the toxin in blood and tissues are discussed.

COLIBACILLARY INFECTIONS. Methods for the differentiation of coliform organisms by the Voges and Proskauer reactions, the methyl red reaction, and the use of Koser's medium, are described.

DIPHTHERIA. The respective merits of the various media suggested for the isolation and identification of the *gravis* and *mitis* strains are compared.

DYSENTERY (BACILLARY). *B. dysenteriae* Schmitz is now recognized as a cause of bacillary dysentery, and the first outbreak in which this strain has been identified in Great Britain has been recorded. The media suggested by Wilson and Blair, and by Leifson, have greatly simplified the isolation of pathogenic bacteria from the intestinal contents.

GAS GANGRENE. The Nagler reaction has been suggested for rapidly identifying *Clostridium welchii* when present as a contaminant of war wounds. The relationship of the causal organism in welchii infections in humans with similar organisms infecting animals is discussed. *Vibrio Septique*, *Cl. œdematiens*, and *Cl. histolyticum* are other gas-forming anærobcs occasionally present in cases of human gas gangrene.

INFLUENZA. Since the isolation of influenza virus by Andrewes and his colleagues, a second type of virus has been recovered from influenza patients. The original virus (now termed virus "A") has not been present in some of the recent outbreaks, and it is possible that a serologically different virus (virus "B") may have been the ætiological agent. The method for the propagation of the virus on the developing chick embryo is described. The possibility of the existence of yet a third influenza virus, which the Americans have termed virus "Y," is discussed by Andrewes.

KALA-AZAR. The medium of Novy, MacNeal and Nicolle for the cultivation of leishmaniæ is used for blood culture in the diagnosis of this infection. The aldehyde test and the antimony test are useful aids to diagnosis but do not give positive results until one and two months respectively from the onset of the disease.

LEPROSY. An important development still under trial is the use of diphtheria antitoxin and diphtheria toxoid in the treatment of this disease.

LYMPHOPATHIA VENEREUM. This term has been adopted in place of the older designation, lympho-granuloma inguinale, in view of the recognition of the wide distribution of the lesions. Frei's antigen is used both for diagnosis and treatment, and may now be prepared from virus cultivated in the yolk sac of the chick embryo, as well as from infected mouse brain.

POLIOMYELITIS. The older view that the virus is transmitted by droplet infection and gains entry *via* the nasal mucosa and the olfactory tract has not satisfactorily explained many features of this disease, and there is now experimental and clinical evidence

to support the view that the most common route of infection is *via* the gastro-intestinal tract. Attempts to control the disease should be made as if it were an enteritis rather than influenza.

RICKETTSIAL DISEASES. The opportunity of this revision has been taken to group together the various rickettsial diseases, such as Japanese river fever, trench fever, Rocky Mountain spotted fever and *Fièvre Boutonneuse*, with the epidemic and non-epidemic group of typhus fevers. The control of these fevers provides a problem in war-time, when American and European troops are transported to endemic regions. Successful results have been reported from various methods of immunization against rickettsial infections, particularly from the use of chick embryo vaccine prepared by Cox's method.

SCARLATINA. Serological investigations have shown that in Great Britain the streptococci of scarlatina belong to Lancefield's group A, the commonest types being I, II, III and IV.

SPRUE. Attention has been directed to the resemblance of this condition to other states of "chronic jejuno-ileal insufficiency"; the similarity of the glossitis and stomatitis of sprue, and those of pellagra, pernicious anæmia, and idiopathic steatorrhœa, suggest a common ætiological factor in this disease-group.

STAPHYLOCOCCI. It has been suggested that staphylococci should be classified on the basis of the property of coagulase production. Some strains of *Staphylococcus aureus* and *Staphylococcus albus* produce a soluble exotoxin which is hæmolytic, dermonecrotic, and lethal to test animals.

STREPTOCOCCI. Study of Lancefield's groups in relation to their epidemiological significance has revealed the presence of streptococci other than group A in a number of human infections. Two serologically distinct varieties of hæmolysin, streptolysin O and streptolysin S have been obtained from group A hæmolytic streptococci. The use of gentian violet in blood agar permits the growth of streptococci whilst inhibiting staphylococci.

TRICHINIASIS. Several outbreaks in Great Britain have provided descriptions of the clinical and pathological features of this disease acquired by eating imperfectly cooked pork. Diagnosis may be assisted by a skin test or a precipitin test, using an antigen prepared from the trichinella larvæ.

TUBERCULOSIS. There is still a very prevalent opinion that bovine strains of the tubercle bacillus are less virulent for man than the human strains. Bacteriological surveys show that in Great Britain, and particularly in Scotland, the bovine strain is at least as virulent as the human form. Flotation methods for the separation of tubercle bacilli from sputum and the Lowenstein-Jensen medium for their isolation are described. A method for the cultivation of *M. tuberculosis* in hæmolysed blood enables cultures to be obtained in from 3 to 7 days.

TYPHOID FEVER. To be of value in diagnosis the Widal reaction must be applied in relation to the antigenic structure of the typhoid and paratyphoid bacilli. Methods for the preparation

of H and O agglutinating sera and antigens are described. The search for carriers among a series of suspected contacts is facilitated by tests for the detection of Vi antigen.

UNDULANT FEVER. The importance of blood cultures for diagnosis in the early stages and of agglutination tests in the later stages of the group of *Brucella* infections is stressed.

WHOOPIING COUGH. The production of an exotoxin from the *Hæmophilus pertussis* has been described; skin reactions and complement fixation tests have been suggested as alternatives to the cough plate method for diagnosis.

YELLOW FEVER. Considerable progress has been made in methods of prophylactic immunization, but a high incidence of jaundice after inoculation with prophylactic vaccine has been reported. Some new facts with regard to epidemiology have been brought to light as a result of the application of the mouse-protection test as an aid to diagnosis.

Acknowledgments

The fullest use has again been made of scientific papers and abstracts published in a wide range of chemical, pharmaceutical and medical periodicals, both British and foreign. The greatest care has been taken to select matter likely to be of most value to medical practitioners, pharmacists and analysts, and every effort made to ensure accuracy. If any errors are noted by readers or users of the book, the Editor will be grateful if his attention is drawn thereto and the Revision Committee will welcome suggestions regarding the subject matter or its arrangement by which the usefulness of *The Extra Pharmacopœia* may be increased.

Assistance has been obtained from several persons having special knowledge of different parts of the work and The Council of the Pharmaceutical Society desire to record their indebtedness to the staff of the Codex Department who have prepared this edition under the direction of the Codex Revision Committee and in particular to the following persons who have assisted them in the revision of certain sections of the book requiring expert knowledge on special subjects:—H. E. Archer, M.R.C.S., L.R.C.P., F.I.C., Ph.C.; H. F. Brewer, M.A., M.D.; Katherine H. Coward, D.Sc.; F. Hartley, Ph.D., B.Sc., B.Pharm., Ph.C.; W. M. Levitt, M.D., F.R.C.P.; Alistair MacGregor, M.D.; A. Maude; W. V. Mayneord, D.Sc.; T. McLachlan, F.I.C.; J. R. Nicholls, D.Sc., F.I.C.; R. Peck; A. H. T. Robb-Smith, M.B., B.S., M.R.C.S., L.R.C.P.; A. I. Robinson, Ph.C.; George Simon, M.D.; J. E. Woodhead, B.Sc., F.I.C., Ph.C., and P. H. Woodnoth, Ph.C.

June, 1943.

ABBREVIATIONS

The abbreviated titles of journals are those given in the *World List of Scientific Periodicals* (2nd Edn., 1934). When the reference is to a periodical of which two volumes are published during a year the number placed first indicates the first or second volume of the year followed by the year, and the last number refers to the page, thus, *Brit. med. J.*, i/1932, 250. When only one volume of a periodical is published each year, the reference gives the year and the page, thus, *Quart. J. Pharm.*, 1934, 341. In other cases the volume number is given in italics in addition to the year and page, thus, *J. biol. Chem.*, 1928, 77, 797.

ANALYTICAL ADDENDA TO CHEMICALS AND MATERIA MEDICA IN VOLUME I.

ACACIA

Acacia (B.P.). Occurs in rounded or ovoid tears and the powder does not comply with the official description. Loses not more than 15% of its weight at 100° and should yield not more than 5% of ash. (All *B.P.* ash values are calculated with reference to the drug dried at 100°.) It should be free from tannins, starch and dextrins and the *B.P.* requires it to be almost entirely soluble in an equal volume of water, but the *U.S.P. XII* permits not more than 1% of water-insoluble residue, limits the ash to 4% and acid-insoluble ash to 0.5% and permits not more than 15% of moisture. *Gomme Arabique, Fr. Cx. 1937*, has a specific rotation in 5% aqueous solution of about -26° .

The best varieties are Kordofan, Mogadore and Senegal gums, but dark-coloured gums are not suitable for medicinal purposes.

Tentative methods for the identification of gums are described in *Methods of Analysis (A.O.A.C., 1940, 596)*. Acacia, tragacanth, starch, quince, Irish moss, agar, karaya and galagum are distinguished by tests with chlorzinciodide, ruthenium red, methylene blue, etc.

Acidity of Gum Acacia. The amount of sodium hydroxide required to neutralise 1000 g. of gum varies from 2.48 to 3.2 g., giving an average of 2.84 g. The clarity of the solution is in no way related to its reaction.

Identification of Common Gums. Acacia, tragacanth, agar, Irish moss, quince, and ghatti gum distinguished by Millon's reagent, lead acetate, potassium hydroxide, tannic acid, etc. *A useful table.—Pharm. J., ii/1931, 46.*

Detection of Karaya, Tragacanth and Agar. One drop of the preparation suitably diluted on a slide is treated with a mixture of zinc iodide and potassium iodide solutions. Karaya particles are coloured green. The particles are seen as irregular billowy masses which are resilient when pressed under a cover slip. Tragacanth is similar in appearance but the masses are more uniform. It can be identified by the characteristic striations. Agar (e.g., in mayonnaise) may be detected by shaking about 50 g. with twice its volume of alcohol, filtering and defatting the residue with ether. The residue is dried and suspended in 50 ml. of cold water to remove soluble gums, dextrin and sugars, and the insoluble product heated rapidly to boiling with 25 ml. of water to remove protein. The liquid is filtered while hot and the filtrate digested with 5 ml. of malt extract, if starch is present, a further 5 ml. being added after 5 minutes digestion. The liquid is concentrated until it gels on cooling and is then tested on a slide with iodine solution. Agar gives a distinct red colour. A method is also given for detecting agar in the presence of other mucilages and of gelatin.—*J. D. Wildman, J. Ass. off. agric. Chem., Wash., 1935, 637.*

ACETANILIDUM

Acetanilidum (B.P.C.). $C_8H_9ON = 135.1$. M.p., 113° to 115° . Ash, not more than 0.1%. Complies with tests for absence of phenacetin and for neutrality. Acetanilide is not included in *B.P.*, but is official in *U.S.P. XII*, *P. Helv. V*, etc. The *Fr. Cx. 1937* includes a limit of water-soluble substances of 0.2%.

Determination. Hydrolyse 1.5 g. by boiling for 15 minutes with 50 ml. of 20% hydrochloric acid and dilute to 500 ml. To 25 ml. of this solution add

excess standard potassium bromide-bromate solution to precipitate tribromoaniline, and estimate excess bromine in the usual way.—*J. chem. Soc. Abstr.*, i/1921, 604.

Tabellæ Acetanilidi (N.F. VII). Contain 92.5 to 107.5% of the labelled amount of acetanilide, including all tolerances. Assayed by extracting a weighed quantity of powdered tablets with chloroform, removal of the chloroform and titrating the residue, dissolved in water and hydrochloric acid, with bromide-bromate solution previously standardised against a pure sample of acetanilide.

Methods for the determination of mixtures of acetanilide with phenacetin, with caffeine, with caffeine and codeine, with caffeine and quinine, with caffeine, quinine and morphine and with sodium salicylate are described in *Methods of Analysis (A.O.A.C., 1940, 559, et seq.)*.

Methylacetanilide. The detection and identification of N-methylacetanilide in mixtures of antipyretics is described.—A. Denoel, per *Analyst*, 1939, 831

ACIDUM ACETICUM

Acidum Aceticum (B.P.). Contains from 32.5 to 33.5% *w/w* of $\text{CH}_3\cdot\text{COOH}$; sp. gr., 1.044 to 1.045. The diluted acid, Acidum Aceticum Dilutum, now contains 6% *w/w*, whereas the corresponding acid of the B.P. '14 contained only 5%. Acidum Aceticum Glaciale (B.P.) contains not less than 99% by weight with a f.p. of not less than 14.8° and a sp. gr. of 1.055 to 1.058.

Glacial acetic acid of the U.S.P. XII contains 99.4% of $\text{CH}_3\cdot\text{COOH}$ and Acidum Aceticum (U.S.P. XII) contains from 36 to 37% by weight of $\text{CH}_3\cdot\text{COOH}$; the glacial acid should have a congealing point not below 15.6° . Acide Acétique, *Fr. Cx.* 1937, contains not less than 98% *w/w* of $\text{CH}_3\cdot\text{COOH}$. The dilute acid is prepared by diluting the 98% acid with 9 parts of water. Acidum aceticum, *P.G. VI*, contains not less than 96% and Acidum aceticum dilutum, *P.G. VI*, from 29.7 to 30.6% of $\text{CH}_3\cdot\text{COOH}$. Acidum aceticum concentratum and Acidum aceticum dilutum, *P. Helv. V*, contain 98 to 100% and 29.5 to 30.5% *w/w* respectively of $\text{CH}_3\cdot\text{COOH}$.

A British Standard Specification (B.S.S. No. 576—1934) has been issued by the British Standards Institution for Glacial Acetic Acid and Dilute Acetic Acids. The specification for Glacial Acetic Acid, 99 to 100%, includes description, acetic acid content, crystallising-point (not lower than 14.8°), residue on evaporation, iron, chlorides, sulphates, heavy metals, substances reducing permanganate, formic acid, aldehydes and ketonic substances, and sampling, and the appendices describe the methods and apparatus to be used. The specification for Dilute Acetic Acids deals with Acetic Acids, 80%, 60%, and 40%. The iron which may be present in these substances is determined colorimetrically by means of thioglycolic acid in the presence of ammonia. B.S.S. No. 578—1934 refers to Technical Acetic Acid, 98 to 100%, and to Technical Acids, 80%, 60%, and 40%.

Potassii Acetas (B.P.). $\text{CH}_3\cdot\text{COOK} = 98.12$. Loses not more than 5% of its weight at 100° and the dried salt contains not less than 99% of $\text{CH}_3\cdot\text{COOK}$ when assayed by ignition and subsequent titration of the alkaline residue with acid. The U.S.P. XII salt is of the same strength after drying to constant weight at 150° . Acétate de Potassium, *Fr. Cx.* 1937, contains 95% of the pure substance, as indicated by the ignited potassium sulphate.

Sodii Acetas (B.P.C.). $\text{CH}_3\cdot\text{COONa}, 3\text{H}_2\text{O} = 136.1$. The crystalline salt should contain the equivalent of 99.5 to 105%

of the pure salt. Sodii Acetas, *N.F. VII*, loses from 36 to 41% of water at 120° and then contains not less than 99% of the pure anhydrous salt.

Thallii Acetas (*B.P.C.*). $\text{CH}_3\cdot\text{COOTl}=263\cdot4$. Assayed gravimetrically by precipitating the base as thallos iodide, and contains not less than 98%.

Zinci Acetas (*B.P.C.*). $(\text{CH}_3\cdot\text{COO})_2\text{Zn}, 2\text{H}_2\text{O}=219\cdot5$. Contains not less than 99·5% of the pure acetate when assayed on its zinc content by precipitation with mercuric ammonium thiocyanate solution and subsequent titration with iodate solution, as described in the Pharmacopœia for Zinci Sulphas. Zinci Acetas, *U.S.P. XII*, contains from 83·16 to 87·32% of $(\text{CH}_3\cdot\text{COO})_2\text{Zn}$, corresponding to not less than 99·5% of the hydrated salt; it is assayed by precipitation as carbonate and weighing as oxide.

Liquor Ammonii Acetatis Dilutus (*B.P.*). Determined by titration of the acetic acid liberated upon fixation of the ammonia with solution of formaldehyde, with *N*/1 sodium hydroxide, using phenolphthalein indicator, contains 6·9 to 7·5% *w/v* of $\text{C}_2\text{H}_7\text{O}_2\text{N}$. Liquor Ammonii Acetatis, *N.F. VII*, contains 6·5 to 7·5% *w/v* of $\text{C}_2\text{H}_7\text{O}_2\text{N}$.

Liquor Ammonii Acetatis Fortis (*B.P.*) contains 55 to 60% *w/v* of $\text{C}_2\text{H}_7\text{O}_2\text{N}$.

Acidum Aminoaceticum (*U.S.P. XII*). $\text{C}_2\text{H}_5\text{O}_2\text{N}=75\cdot07$. Loses not more than 0·2% at 100° and then contains 18·4 to 18·8% of *N*, corresponding to 98·5% of $\text{C}_2\text{H}_5\text{O}_2\text{N}$, when assayed by the Kjeldahl method. Ash, not more than 0·1%.

Acidum Trichloroaceticum (*B.P.*). $\text{CCl}_3\cdot\text{COOH}=163\cdot4$. Assayed by ignition with sodium carbonate and titration of the chloride formed with silver nitrate and ammonium thiocyanate and contains not less than 98% of the pure acid. The *U.S.P. XII* acid, dried to constant weight over sulphuric acid, contains not less than 99% and is assayed by titration with normal sodium hydroxide solution. The *P. Helv. V* requires a content of 99·64% of $\text{CCl}_3\cdot\text{COOH}$, and the acid should have a solidifying point of 55° to 59°.

Acetonum (*B.P.*). Sp. gr. at 15·5°, 0·796 to 0·801. At least 95% by volume distils between 56° and 58° when measured under standard conditions. Tests for alkalinity, acidity, oxidisable substances, moisture, and residue on evaporation are also prescribed. The *U.S.P. XII* prescribes an iodometric method for the assay of acetone and requires it to contain not less than 99% by weight of $\text{CH}_3\cdot\text{CO}\cdot\text{CH}_3$. Acétone, *Fr. Cx. 1937*, by iodometric assay contains not less than 98% of the pure substance.

Diacetone Alcohol. A British Standard Specification for Diacetone Alcohol, 4-hydroxy-4-methyl-pentanone-2 (*B.S.S. No. 549—1934*), includes requirements regarding description, specific gravity, distillation range, flash-point, miscibility with water, water, acidity, and sampling.

Amyl Acetate. A British Standard Specification (*B.S.S. No. 552—1934*) for Amyl Acetate includes requirements regarding description, specific gravity, distillation range, residue on evaporation, water, acidity, ester content, and sampling.

Æthylis Acetas (B.P.C.), determined by treatment with N/1 sodium hydroxide during 30 mins. and back titration with standard acid to phenolphthalein, contains not less than 90% w/w of $C_4H_8O_2$. **Æthylis Acetas, N.F. VII**, contains not less than 99% of $C_4H_8O_2$; in assaying, the sample is refluxed on a water-bath for one hour with the standard alkali.

A specification for Ethyl Acetate (B.S.S. No. 553—1934) includes requirements regarding description, specific gravity, distillation range, residue on evaporation, water, acidity, ester content (not less than 96%), and sampling.

Normal Butyl Acetate. B.S.S. No. 551—1934 for Normal Butyl Acetate (acetic ester of primary normal butyl alcohol) includes requirements regarding description, specific gravity, distillation range, residue on evaporation, acidity, ester content, and sampling. The appendices describe the methods and apparatus to be used.

Carbacholum (B.P. Add. III). $C_6H_5O_2N_2Cl = 182.6$. Loses not more than 0.5% at 110° , and then contains not less than 99.5% of the pure substance, by titration with N/10 silver nitrate to potassium chromate indicator. M.p. (with decomposition), 210° to 212° . Residue on incineration, not more than 0.1%.

ACIDUM ACETYSALICYLICUM

Acidum Acetylsalicylicum (B.P.). Assayed by hydrolysis with excess of N/2 sodium hydroxide and titration with acid with a blank experiment under the same conditions. It contains not less than 99.5% of the pure compound, has a m.p. of 135° to 138° and a limit test for free salicylic acid by which the proportion does not exceed about 0.05%.

The m.p. of the U.S.P. XII product is not below 135° and the test for free salicylic acid is equivalent to about 0.1%. **Acidum acetylsalicylicum, P. Helv. V**, is determined by titrating a solution in alcohol to phenolphthalein with N/10 sodium hydroxide and contains from 99.5 to 100% of the pure substance.

Tabellæ Acidi Acetylsalicylici (U.S.P. XII). Contain 95 to 105% of the labelled amount of $C_9H_8O_4$, including all tolerances. Assayed by suspending a weighed quantity of the powdered tablets in neutral alcohol and titration with N/10 sodium hydroxide using phenolphthalein indicator, then adding a known excess of N/10 sodium hydroxide to the titration flask and heating on a boiling water bath for 15 minutes, and finally cooling and titrating against N/10 sulphuric acid. A blank titration is performed.

An official method for the determination of acetylsalicylic acid in tablets containing phenacetin and caffeine is described in *Methods of Analysis (A.O.A.C., 1940, 569)*. 0.2 g. of the powdered tablets with water are completely extracted with chloroform and the chloroform evaporated to about 2 ml. 10 ml. of sulphuric acid (1+9) is added, and the mixture digested, the flask partly in a boiling water-bath and connected to a reflux condenser, for 30 mins. The caffeine and salicylic acid are then extracted from the mixture with chloroform, the salicylic acid transferred to 5% sodium carbonate solution and the solution, after evaporating any chloroform, diluted to 100 ml. with water. 25 to 40 ml. of 0.2N iodine is then added and digested for 1 hour on a steam-bath, the free iodine removed with a few drops of sodium thiosulphate solution, the precipitate collected on a Gooch, washed, dried at 100° and weighed. The weight of tetraiodophenylenequinone ($C_6H_2I_4O_2$) $\times 0.4016$ = total salicylic acid. Deduct any free salicylic acid present. $\text{Salicylic acid} \times 1.304$ = acetylsalicylic acid.

Assay of Aspirin, Phenacetin and Caffeine tablets. Determine the acetylsalicylic acid by dissolving about 0.5 g. of powdered sample in alcohol, titrating with N/10 sodium hydroxide, adding excess of alkali, refluxing and back-titrating with acid. The phenacetin and caffeine are determined together

by dissolving in water with a little alkali, and shaking out with chloroform. The extracted material is refluxed with dilute sulphuric acid and the caffeine shaken out with chloroform and weighed. The acid solution remaining is neutralised with sodium bicarbonate. After the addition of a few drops of acetic anhydride, the mixture is shaken out with chloroform. This operation is repeated four times, the chloroform solution is evaporated to dryness and the phenacetin weighed.—P. Sorgdrager, *Pharm. Tijdscher. Ned. Indie*, 1940, 17, 227.

Determination of Free Salicylic Acid in Acetylsalicylic Acid. Dissolve salicylic acid, 1 g., in alcohol, 60 ml., and adjust to 100 ml. with water. 10 ml. of this solution may then be diluted to 1000 ml. for the standard, making 1 ml. = 0.0001 g. acid. Dissolve 0.6 g. of the sample to be tested in 9 ml. of alcohol, dilute with water to 90 ml. and mix well. Take two exactly similar Nessler glasses. Into one pour 60 ml. of the solution, into the other the remaining 30 ml., together with 3 ml. of alcohol, and adjust to the volume of the first. This gives a difference of 0.2 g. of acetylsalicylic acid in similar mixtures of alcohol and water. One ml. of a 1% solution of iron alum is added to each, mixed, and the colour matched by adding the salicylic acid solution.—A. J. Jones, *Chem. & Drugg.*, 1919, 402.

Official methods for the determination of free and total salicylic acid in acetylsalicylic acid are described in *Methods of Analysis (A.O.A.C., 1940, 567)*.

A solution yields a buff-coloured precipitate with ferric chloride until hydrolysed by the addition of a little hydrochloric acid, which yields the typical violet colour of salicylate (developing particularly on warming).

The ferric chloride test for free salicylic acid in acetylsalicylic acid is insufficient to prevent adulteration, etc., in that the addition of borax, sodium phosphate, tartaric acid, citric acid and other oxy-acids will readily prevent or mask the colour ordinarily produced with ferric chloride.

Tartaric Acid added to aspirin tablets would mask the ferric iron test if salicylic acid were present. 1% of citric acid will mask the presence of 0.2% of free salicylic acid.—A. Nutter Smith, *Chem. & Drugg.*, ii/1930, 1630.

Determination of Free Acetic Acid. A. Nutter Smith (*Yearb. Pharm.*, 1920, 421) described a process by which the sample (1 g.) previously finely powdered is spread on muslin and the acetic acid evolved is aspirated into 50 or 100 ml. of distilled water for $\frac{1}{2}$ or 1 hour. The liquid is then titrated with N/500 caustic soda. Each ml. of this represents 0.00012 g. of acetic acid.

The decomposition of acetylsalicylic acid in aqueous solution in the presence of alkali citrate or acetate is independent of the concentration of the salt or of the acid. Solutions (at room temperature) decompose about 10% during the first day and 50% in a week. The rate of decomposition increases very rapidly with rise of temperature.—C. Morton, *Quart. J. Pharm.*, 1933, 495.

Calcii Acetylsalicylas (B.P.C.).

$(\text{CH}_3\text{CO}\cdot\text{OC}_6\text{H}_4\cdot\text{COO})_2\text{Ca}\cdot 2\text{H}_2\text{O} = 434.2$. Contains not less than 95% when assayed by weighing the sulphate formed on ignition with sulphuric acid.

ACIDUM BENZOICUM

Acidum Benzoicum (B.P.). $\text{C}_6\text{H}_5\cdot\text{COOH} = 122.0$. The natural and synthetic acids are official; at least 99.5% of free acid must be present and a limit test for chlorinated compounds is prescribed. M.p., 121° to 122° . The U.S.P. XII acid, after drying at 100° for 2 hours, contains not less than 99.3%; the solution in dilute alcohol neutralised to phenolphthalein is titrated with standard sodium hydroxide and a correction is applied for the proportion of chlorinated compounds present. *Acide Benzoique*, *Fr. Cx.* 1937, melts at 121° and contains not less than 99% of the pure substance. Both *Acidum benzoicum* and *Acidum benzoicum e resina* are official in the *P. Helv. V*; the former melts at 120.5° to 121.5° and the latter between 118° and 121° .

Detection in Foodstuffs. Extract with a mixture of ether and petroleum ether in equal parts; this evaporated may contain saccharin (taste), salicylic acid (by its colour with ferric chloride), and benzoic acid—recognised by odour, crystalline form, and conversion into aniline blue by heating with rosaniline and aniline.

Colorimetric Estimation in Cordials, Etc. The aniline blue reaction is unsatisfactory, as acetic, succinic and salicylic acids also give the reaction. Best results with a modification of Halphen's Reaction, hydroxylamine hydrochloride being employed as reducing agent. Presence of benzoic acid indicated by fine red colour.—A. J. Jones, *Yearb. Pharm.*, 1925, 493.

Caution needed in search for traces of preservatives in caramel and boiled sugar sweets, which yield a crystalline acid substance (m.p. 122°), giving a violet colour with ferric chloride, similar to benzoic acid.—per *Yearb. Pharm.*, 1927, 185.

Determination in Foodstuffs (Fruits and Vegetables), in permitted amounts, specified under the Regulations in force since Jan. 1, 1927. A lengthy process, starting with steam distillation after saturating if necessary with salt, and subliming in presence of sand for 1 to 1½ hours at 160°, and ultimately weighing the benzoic acid present.—G. W. Monier-Williams, *Rep. publ. Hlth med. Subj.*, No. 39, 1927, per *Yearb. Pharm.*, 1927, 182.

In the Monier-Williams method it is quite clear that unless the oven used for sublimation is arranged to agree in all respects with the one described, either a higher temperature or a longer time may be required for quantitative recovery of the benzoic acid.—R. W. Sutton and O. Hitchen, *Analyst*, 1940, 502.

The application of Grossfield's modification of Mohler's test for benzoic acid to the detection and determination in foodstuffs is described. Details are given of the results obtained on various foods and the percentage errors are recorded for 31 different articles.—E. T. Illing, *Analyst*, 1932, 224.

Various methods of estimation of benzoates and salicylates.—E. B. R. Prideaux and A. O. Bentley, *Pharm. J.*, 1/1923, 427.

A distillation method of determination in foods (butter, margarine, and egg products) and in wines (not sweet).—per *Yearb. Pharm.*, 1927, 183. Also an adaptation of the French official method for detection in wines, showing 1 mg. in 100 ml. of wine.—*ibid.*, 1925, 149.

Official methods for detection and estimation of benzoic acid in foods are described in *Methods of Analysis (A.O.A.C.)*, 1940, 456).

The following method, a modification of Nicholls's method (*Analyst*, 1928, 19), was found to be more satisfactory when dealing with food products. Reagents required:—(A) *Iron solution for oxidation*.—A solution of 2.7 g. of anhydrous ferric chloride in 13 ml. of N/1 sulphuric acid made up to 100 ml. with water. (B) *Iron solution for colorimetric determination*.—0.1 g. of anhydrous ferric chloride in 20 ml. of N/1 hydrochloric acid diluted to 100 ml. with water. (This solution eliminates interference due to *p*-hydroxybenzoic acid and other compounds.) (C) 0.2% hydrogen peroxide solution prepared by diluting 2 ml. of 20 vol. solution to 60 ml. with water. The benzoic acid is isolated by extraction with an immiscible solvent or by steam distillation from an acid solution saturated with salt. The acid is neutralised with dilute ammonia, the excess of ammonia removed by boiling until the vapours are neutral to litmus, and the solution made up to a definite volume. To an aliquot portion, containing not more than 5 mg. of benzoic acid, is added 5 ml. of N/10 sulphuric acid and water to 15 ml., followed by 1 ml. of iron solution A and 1 ml. of 0.2% peroxide solution, the mixture being well mixed and then heated in a boiling water-bath for 15 minutes. The product is treated with about 5 g. of ammonium sulphate and the salicylic acid extracted with three successive quantities, each of 15 ml., of ether, each ethereal extract being washed with 5 ml. of water. The ether is distilled off at 50°, the residue dissolved in 50 ml. of alcohol 10%, and the solution treated with 1 ml. of iron solution B. The colour produced is compared with that given by a standard solution of salicylic acid in 10% alcohol. The weight of benzoic acid originally present may be found from the weight of salicylic acid produced by means of the following table:—

| | | | | | | | | |
|--|------|------|-----|------|-----|------|------|------|
| Salicylic acid formed, mg. | 0.1 | 0.15 | 0.2 | 0.25 | 0.3 | 0.35 | 0.4 | 0.45 |
| Benzoic acid originally present, mg. . . | 0.77 | 1.25 | 1.8 | 2.3 | 2.8 | 3.3 | 3.85 | 5.0 |

The method is specific so far as is known, with the exception of saccharin, and if this is present the separated benzoic acid must be extracted with carbon tetrachloride in which saccharin is insoluble.—F. W. Edwards, H. R. Nanji and M. K. Hassan, *Analyst*, 1937, 172.

Ammonii Benzoas (B.P.C.). $C_6H_5 \cdot COONH_4 = 139.1$. Contains not less than 98% and is assayed by adding excess of standard acid, separating the benzoic acid by means of ether and titrating the excess of acid with sodium hydroxide using phenol red as indicator.

Benzylis Benzoas (B.P. Add. IV). $C_6H_5 \cdot COOCH_2 \cdot C_6H_5 = 212.1$. The *B.P.* method for esters in essential oils with 2 hours boiling over a flame is used and a percentage of not less than 99 is required. Sp. gr., 1.121 to 1.125; freezing point not below 18.5° . $n_{D^{20}}$, 1.568 to 1.570. Ash, not more than 0.05%. Benzylis Succinas, *B.P.C.*, is required to have a purity of 99% and is assayed by the same method.

Sodii Benzoas (B.P.). $C_6H_5 \cdot COONa = 144.0$. Moisture at 110° not more than 4% and the dried salt contains not less than 99% of the pure benzoate. The method of assay of the *B.P.* 1914, in which the alkaline residue obtained on ignition was titrated, is replaced by the ether-acid process in which the alkali of a neutralised solution is titrated with standard sulphuric acid to bromophenol blue after removing most of the liberated benzoic acid with ether. Sodii Benzoas, *U.S.P. XII*, after drying at 110° , contains not less than 99%, assayed by titration of an ethereal mixture with $N/2$ hydrochloric acid, using methyl orange indicator. The *Fr. Cx.* 1937 substance loses not more than 3% at 100° ; contains not less than 97% of the pure substance.

Ammonii Hippuras (B.P.C.). $C_6H_5 \cdot CO \cdot NH \cdot CH_2 \cdot COONH_4 = 196.1$. This ammonium salt is readily soluble and should not contain any appreciable amount of free hippuric acid. When assayed for nitrogen by the Kjeldahl method it must contain the equivalent of not less than 98% of the pure hippurate.

Acidum Cinnamicum (B.P.C.). $C_6H_5 \cdot CH : CH \cdot COOH = 148.1$. Determined in the same way as benzoic acid, it is required to contain not less than 99%. Benzoic acid is tested for by titrating the filtrate obtained after shaking 1 g. with 100 ml. of boiled and cooled water at 20° for 1 hour, and must not exceed about 4%.

Coumarinum (B.P.C.). $C_9H_6O_2 = 146.1$. Melts between 68° and 70° , with limit of 0.05% for ash and test for absence of acetanilide and readily carbonisable matter.

Vanillinum (B.P.C.). 4-Hydroxy-3-methoxybenzaldehyde, $CH_3O \cdot C_6H_3(OH) \cdot CHO = 152.1$. Melts between 80° and 82° , with limit of 0.05% for ash and a carbylamine test on 0.1 g. for absence of acetanilide. It is official in the *U.S.P. XII* and the standard of purity is the same as that of the *B.P.C.* Vanilla, *N.F. VII*, yields not less than 12% of anhydrous dilute alcohol extractive.

Official methods for the determination of vanillin and coumarin in flavouring agents are described in *Methods of Analysis (A.O.A.C., 1940, 320)*. 50 ml. of an extract is diluted to 80 ml. and evaporated to 50 ml., repeating this operation, 25 ml. of lead acetate (8%) solution added, adjusted to 100 ml., shaken, stood for 18 hours and filtered. 50 ml. of the filtrate is extracted with ether, the ether washed with ammonia water (1 + 11), the ammoniacal solutions acidified with

hydrochloric acid (1 + 2) and extracted with ether. After evaporating the ether, the residue of vanillin is weighed and should melt at about 80°. For coumarin, the first ether extract is evaporated and weighed. The residue should melt at 67° and on addition of a few drops of N/10 iodine to 0.5 ml. of hot solution a brown precipitate, gathering into green flecks, should be produced. The colorimetric method for vanillin consists of clearing a solution of 8 to 12 mg. with 4 ml. of lead solution (5% each neutral and basic lead acetate), diluting to 100 ml. and filtering. To 5 ml. of filtrate and 5 ml. of standard vanillin solution (0.1 mg. per ml.) 5 ml. of phosphotungstic-phosphomolybdic acid reagent is added respectively and diluted with saturated sodium carbonate solution to 50 ml. After filtering the solutions the blue colours produced are compared.

"Ethyl" Vanillin (*m*-ethoxy-*p*-hydroxybenzaldehyde) has chemical properties very closely resembling those of vanillin and is four or five times stronger in flavour. It can be determined by a bromine absorption method.—H. C. Lockwood, *Analyst*, 1934, 730.

Differentiation from Vanillin: Dissolve in hydrochloric acid, cool, add hydrogen peroxide, shake, and stand until precipitation complete. Add an equal volume of benzene, shake. The blue precipitate of vanillin remains in the aqueous layer, whereas that of the "ethyl" vanillin dissolves in the benzene to give a violet solution.—P. Stadler and K. Wagner, *Z. anal. Chem.*, 1938, *III*, 391–393.

Determination of Coumarin in Presence of Vanillin. Coumarin can be separated from vanillin in extracts of vanilla or other plant extracts by steam distillation in the presence of potassium sulphate (0.5 g. for 10 to 12.5 ml. of extract). The extract is diluted with 100 ml. of water and the distillation is conducted with dry steam, the pressure being reduced to 140 mm., until the contents of the distillation flask are evaporated to dryness. 100 ml. of water is then added and the distillation repeated. The condenser is rinsed down and the distillate diluted to 1000 ml. To 20 ml. in a 50 ml. graduated flask is added 5 ml. of 2% sodium carbonate solution, the liquid is then heated in a boiling water-bath for 5 to 10 minutes and cooled. 5 ml. of cold diazonium solution is added and the mixture diluted to volume. After standing 15 minutes, colorimetric comparison is made with standards containing known amounts of coumarin and treated similarly. The diazonium solution is prepared as follows: 3.5 g. of *p*-nitroaniline is dissolved in 45 ml. of concentrated hydrochloric acid and the solution diluted to 500 ml. This solution and a 5% *w/v* solution of sodium nitrite are stored in a refrigerator at 0° to 3°. 5 ml. of each solution is mixed in a 100 ml. flask, cooled in the refrigerator for 5 minutes, then 10 ml. of nitrite solution added, and the mixture cooled again and finally diluted to 100 ml. with ice-cold water. The resulting solution is cooled for 15 minutes before use.—J. Duncan and R. B. Dustman, *Industr. Engng Chem. (anal. Edn.)*, 1937, 416.

Determination of β -Ionone in Flavouring Substances. A solution of the flavouring substance containing 1 to 10 mg. of β -ionone in 5 ml. of alcohol is treated with 90 to 95 mg. of solid *m*-nitrobenz-hydrazide and the mixture is warmed (without loss of alcohol) on a steam bath. Warm water (10 ml.) is added, and if the solution becomes cloudy it is warmed until clear. It is then treated with 0.2 ml. of glacial acetic acid and the lightly stoppered flask is allowed to cool slowly. If 2 mg. or more of β -ionone are present, crystals begin to form within 30 minutes after the mixture has attained room temperature. The crystallising liquid is allowed to stand for at least two hours and is then placed in a refrigerator overnight or for a period not exceeding 48 hours, and is filtered through a sintered glass crucible with the aid of suction. The crystals are washed with 15 ml. of cold 30% alcohol and dried in a vacuum oven at 70°. The weight of β -ionone is found by multiplying the weight of the precipitate by 0.541.—J. B. Wilson, *J. Ass. off. agric. Chem., Wash.*, 1939, 22, 378.

ACIDUM BORICUM

Acidum Boricum (B.P.). H_3BO_3 = 61.84. Contains not less than 99.5%, determined by titration with sodium hydroxide with the addition of glycerin, and phenol violet as indicator; it complies with a test for solubility in boiling alcohol. It is official

in the *U.S.P. XII*, and after drying over sulphuric acid, should contain not less than 99.5% of the pure substance, using phenolphthalein as indicator and a 50% concentration of glycerin being used in the titration.

Detection of Boric Acid. See also *Milk Analysis*, p. 795.

Moisten congo red paper with a saturated aqueous solution and dry over a small flame; a blue colour is gradually developed. By using 1 in 1000 solution of congo red in a capsule and adding a little of a boric acid solution the presence of 0.00001 g. may be detected. The test is best applied to methyl or ethyl boric ester obtained by distillation.—per *Yearb. Pharm.*, 1925, 138.

The solution suspected to contain a borate is made slightly alkaline with sodium hydroxide and evaporated practically to dryness. The residue is treated with 1 ml. of concentrated sulphuric acid and cooled. 2 ml. of methyl alcohol is added and the mixture is transferred to a test tube fitted with a rubber stopper and two glass tubes. One of these extending to the bottom is bent at right angles and acts as a mouthpiece. The other conducts the vapours and is also bent, but drawn to a long capillary at least 3 cm. long and not more than 0.5 mm. bore. When air is blown through the apparatus the bubbles rising through the heated solution convey volatile methyl borate (if present), which tints a small bunsen flame a characteristic green colour.—A. Gabriel and H. G. Tanner, *J. Amer. chem. Soc.*, per *Chem. & Drugg.*, ii/1928, 777.

Sensitive Reaction. A 0.05% solution of carmine in strong sulphuric acid changes from red to blue in the presence of boric acid.—F. P. Zorbin, per *J. Amer. pharm. Ass.*, 1938, 353.

Official qualitative and quantitative methods for the determination of boric acid and borates in foods are described in *Methods of Analysis (A.O.A.C., 1940, 459)*.

Determination in Foodstuffs. 40 to 50 g. of sample is moistened with 10 ml. of 2N sodium hydroxide, the water evaporated on a steam-bath and the sample ashed. The ash is transferred to a Kjeldahl flask using the minimum quantity of water, the dish is rinsed with dilute sulphuric acid, and the ash in the flask dissolved in a further quantity of the acid by warming. Methyl red is added, followed by 30% sodium hydroxide until the liquid is alkaline, and the contents of the flask are then evaporated over a Bunsen flame, with continuous agitation, to 1 to 2 ml. After cooling, 60 ml. of methyl alcohol and 1 ml. of methyl red solution are added, followed by concentrated sulphuric acid to render strongly acid. The Kjeldahl flask is closed with a cork through which pass two tubes. One leads into a vertical double surface condenser, the exit tube of which is elongated and dips beneath the surface of alkaline methyl alcohol in a 400 ml. conical flask. The other passes to the bottom of the Kjeldahl flask and connects directly with the conical flask, its exterior portion being lagged by enclosure in a rubber tube. Immediately above the stopper of the conical flask is a side-tube sealed on to the condenser outlet; the side-tube runs up close to the condenser and carries a splash-bulb and funnel. The conical flask contains 0.5 ml. of N/1 sodium hydroxide and a few drops of phenolphthalein solution. The Kjeldahl flask is attached to the apparatus at an angle of 30° and is heated. When sufficient methyl alcohol has collected in the conical flask, the latter is also strongly heated so that the vapour bubbles through the liquid in the Kjeldahl flask. After 30 minutes the Kjeldahl flask is cooled in a beaker of cold water, the conical flask is removed and the condenser tube is washed into it with water. The remaining methyl alcohol is boiled off, the solution acidified to methyl red with N/10 sulphuric acid, boiled to remove carbon dioxide and readjusted when cold with N/20 sodium hydroxide until just not acid, more phenolphthalein added and then the solution is titrated to the phenolphthalein end-point in the presence of 1 g. of mannitol. A blank determination is also made on water. 1 ml. of N/20 sodium hydroxide corresponds to 0.0031 g. of boric acid.—R. S. Alcock, *Analyst*, 1937, 522.

Carbasus Acidi Borici (B.P.C. Supp. IV). Assayed by the process of the *B.P.C.* Shake in a stoppered bottle, a weighed quantity of the gauze (equivalent to about a quarter square yard) with 50 parts of boiled water and 40 parts of glycerin; cool and titrate with N/1 sodium hydroxide to phenolphthalein or phenol violet; from 4 to 6% of H_2BO_3 should be indicated.

Gossypium Acidi Borici (B.P.C. Supp. IV). Treated in the same manner as *Carbasus Acidi Borici* it contains from 4 to 6% of H_2BO_3 .

Linteum Acidi Borici (*B.P.C. Supp. IV*). Determined as for Carbasus Acidi Borici, contains 4 to 6% of H_2BO_3 . A piece of lint (measuring 3 inches by 3 inches) becomes saturated within 12 seconds when placed lightly, unraised side downwards, on the surface of water at 20° .

Borax (*B.P.*). $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O} = 381.4$. Assayed by the same method as boric acid, after neutralisation to methyl orange with sulphuric acid, it contains not less than 99% or more than the equivalent of 103% of $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$. *Sodii Boras, U.S.P. XII*, contains 52.32 to 54.92% of the anhydrous salt corresponding to not less than 99% of the crystallised substance, determined by titration with N/2 hydrochloric acid, using methyl red indicator. *Borate de Sodium Officinal, Fr. Cx. 1937*, by titration in glycerin and water with N/1 sodium hydroxide to phenolphthalein, contains not less than 99% of the pure substance. 1 ml. N/1 sodium hydroxide = 0.1907 g. Borax, *P.G. VI*, contains 52.3 to 54.3% of anhydrous sodium tetraborate, $\text{Na}_2\text{B}_4\text{O}_7$.

Sodii Perboras (*B.P.C.*). $\text{NaBO}_3 \cdot 4\text{H}_2\text{O} = 153.9$. Estimated by means of its oxidising action on potassium iodide in acidified solution and titration of the liberated iodine with sodium thio-sulphate, it contains from 96% to the equivalent of 103% of $\text{NaBO}_3 \cdot 4\text{H}_2\text{O}$. *Sodii Perboras, U.S.P. XII*, by titration with potassium permanganate, contains 9% of available oxygen, corresponding to about 86.5% of $\text{NaBO}_3 \cdot 4\text{H}_2\text{O}$. The substance of the *Fr. Cx. 1937*, by titration with N/10 potassium permanganate, contains not less than 86.6% of the pure salt corresponding to 9% of active oxygen.

ACIDUM CITRICUM

Acidum Citricum (*B.P.*) $\text{C}_3\text{H}_4(\text{OH})(\text{COOH})_3 \cdot \text{H}_2\text{O} = 210.1$. Assayed by titration with sodium hydroxide, using thymol blue as indicator, it should contain from 99.5% to the equivalent of 101% of the pure substance; limits of tartaric and oxalic acids are included. The *U.S.P. XII* requires a standard of purity of 97% but uses phenolphthalein as indicator for titration; 0.5 g. with 5 ml. of sulphuric acid kept at 90° for 1 hour, should be no darker than a specified control fluid.

A method for the determination of citrate by oxidation with potassium permanganate in the presence of mercuric sulphate in which formates, tartrates, etc., do not interfere.—W. F. Bruce, *Ind. Engng Chem. (anal. Edn.)*, 1934, 283.

Detection of Citric and Tartaric Acids, etc., in Presence of Sugar. The charring due to the presence of only a trace of sugar is sufficient to mask the colour produced in the resorcinol and sulphuric acid test for tartaric acid. The acids may be separated from sugar by shaking with methylated ether in which they are sufficiently soluble to yield a positive reaction when the test is applied to the residue obtained on evaporating the solution. 5 g. of sample is shaken for about 1 minute with 10 ml. of the ether and then filtered. The ether is evaporated and 1 ml. of water added. 2 to 3 drops of the solution are tested for tartaric acid with resorcinol and sulphuric acid. The remainder of the solution is tested for citric acid with mercuric sulphate and potassium permanganate. If a negative or only a slight positive reaction for tartrate is obtained, the same amount of sample should be tested for cream of tartar by shaking with acidified ether (1 drop of dilute sulphuric acid to 20 ml. of ether) and proceeding as before.—R. de Giacomi, *Analyst* 1937, 731.

Determination of Citric Acid in Mixtures containing also Sucrose and Tartaric Acid. A dilute solution of the citric acid is treated with sulphuric acid and potassium bromide solution; after addition of 5% potassium permanganate solution until a brown precipitate persists, followed, after one hour, by ferrous sulphate in 1% sulphuric acid (20%), the mixture is kept at 0° overnight; the filtered and washed precipitate is then dried in a vacuum desiccator, dissolved out with spirit and ether and the dried crucible again weighed. The difference in weight = pentabromacetone, a correction being made for the volume of filtrate and washings.—Lampitt and Rooke, *Analyst*, 1936, 654.

The method of Lampitt and Rooke does not give good results in the presence of sucrose, maltose or any other readily oxidised material. Modifications are given rendering the process more suitable for milk and milk products.—P. S. Arup, *Analyst*, 1938, 635.

Liquor Magnesii Citratis (U.S.P. XII). Contains magnesium citrate equivalent to 1.6 to 1.9% *w/v* of MgO , determined by precipitation and ignition to $Mg_2P_2O_7$.

Mangani Citras Solubilis (N.F. VII). Contains 48 to 52% of $(C_6H_5O_7)_2Mn_2$. Determined by precipitation with ammonia and hydrogen peroxide, followed by ignition of the precipitate to manganous-manganic oxide.

Potassii Citras (B.P. Add. I). $C_6H_5O_7K_3 \cdot H_2O = 324.4$. By titration of the ash with standard sulphuric acid it contains not less than 99% of $C_6H_5O_7K_3 \cdot H_2O$. Limit tests for tartrate and oxalate are included. 2 g. boiled with 25 ml. of water and cooled requires for neutralisation to thymol blue, not more than 0.5 ml. of N/10 sulphuric acid or of N/10 sodium hydroxide. The U.S.P. XII salt is assayed similarly and after drying to constant weight at 180° contains 99%. Loss at 180°, 3 to 6%.

Sodii Citras (B.P. Add. I). $C_6H_5O_7Na_3 \cdot 2H_2O = 294.1$. Assayed by the same method as the potassium salt it is required to contain 99% of the pure substance. Complies with the test for alkalinity or acidity described under Potassii Citras. The U.S.P. XII requires the same purity after drying at 150°; moisture loss at 150° 10 to 13%. The *Fr. Cx.* 1937, by weight as sulphate, requires a purity of 99%. Natrium citricum tribasicum, *P. Helv. V*, is the crystalline salt containing $5\frac{1}{2}$ molecules of water of crystallisation; by ignition and titration of the alkaline residue it should yield the equivalent of not less than 98% of $C_6H_5O_7Na_3 \cdot 5\frac{1}{2}H_2O$.

ACIDUM FORMICUM

Acidum Formicum (B.P.C.). Contains not less than 24% and not more than 26% *w/w* of $H \cdot COOH$ when assayed by digestion with alkaline potassium permanganate, the excess permanganate being titrated in acid solution with oxalic acid and a blank experiment made. Tests for the absence of acrolein and allyl formate and for limits of non-volatile matter and acetic acid are prescribed. Acidum Formicum, *N.F. VII*, is of the same strength, when the total acidity is titrated with sodium hydroxide. Acidum formicum, *P.G. VI*, contains 24 to 25% of $H \cdot COOH$. Acidum formicum, *P. Helv. V*, contains 24 to 25% *w/w* of $H \cdot COOH$.

An official quantitative method for the determination of formic acid in foods is described in *Methods of Analysis (A.O.A.C., 1940, 466)*.

Determination of formic acid in foodstuffs.—J. Grossfeld and R. Payfer, per *Analyst*, 1940, 168.

Calcii Formas (B.P.C.). $(\text{H}\cdot\text{COO})_2\text{Ca}=130\cdot1$. Determined by the same method as formic acid it should contain not less than 98% of the pure substance.

Potassii Formas (B.P.C.). $\text{H}\cdot\text{COOK}=84\cdot10$. Estimated for formate content, equivalent to 95% of $\text{H}\cdot\text{COOK}$.

Sodii Formas (B.P.C. Supp. IV). $\text{H}\cdot\text{COONa}=68\cdot2$. Assayed by the method for calcium formate, it contains not less than 96% of the pure substance.

ACIDUM GLYCEROPHOSPHORICUM

Acidum Glycerophosphoricum (B.P.C.). Contains 19 to 21% *w/w* of $\text{C}_3\text{H}_5\text{O}_4\text{P}$; limit of combined alkali (as Na_2O), 0·5%; limit of free phosphate (as P_2O_5), 0·5%. Assayed by the *B.P.C.* '34 process by titration with normal sodium hydroxide to bromocresol green and titration with sodium hydroxide to thymol blue, followed by boiling with neutralised calcium chloride solution and further titration to thymol blue, the latter indicating free phosphoric acid present; the difference between the first thymol blue titration and twice the bromocresol green indicates the combined alkali present, and the first thymol blue titration less the free phosphate and the bromocresol green titration represents the glycerophosphoric acid, calculated on the neutralisation of one H ion. Free glycerin is determined by separating the glycerophosphate as calcium salt from alcoholic solution, evaporating and drying the filtrate, and should not exceed 2%.

The analysis of glycerophosphate syrups.—G. Middleton, *Yearb. Pharm.*, 1926, 421.

The alkali and alkaline earth salts of glycerophosphoric acid on the English market are for the most part perfectly definite salts and of reasonable purity. The most noticeable difference between the products of different manufacturers is the considerable variation in the amount of water of crystallisation, especially in the magnesium and 50% sodium salts. The majority are not adjusted to a basis of 50% of anhydrous salt. The 50% potash salt appears to be.—G. J. W. Ferrey, *Yearb. Pharm.*, 1926, 481.

Determination of Orthophosphates in Glycerophosphates. This can be effected by precipitation as ammonium phosphomolybdate under conditions calculated to secure complete precipitation.

Solution A—Molybdic anhydride 100 g., strong solution of ammonia 120 ml. water 300 ml. Dissolve by warming, add 380 ml. of water and cool.

Solution B—Concentrated nitric acid 300 ml., ammonium nitrate 20 g., water 900 ml. Add solution A to solution B with constant stirring, allow to stand 24 hours and filter through a fine paper immediately before use. Store in a cool place. Place about 1 to 5 g. of sample (sufficient to give about 0·15 g. of precipitate), accurately weighed, in a 150 ml. beaker and add 10 ml. of water. For the Na, Ca and Mn salts add nitric acid drop by drop to complete solution and render it acid to methyl orange; in the case of the ferric salt warm on a steam-bath to dissolve, stirring constantly. If solution is incomplete, filter. In a second beaker warm 100 ml. of the reagent to 55° on a steam-bath. Pour the warm reagent into the sample, stir, allow to stand 15 to 20 minutes, filter through a Gooch crucible dried at 120° to 130°, wash thoroughly with water acidified with 5 ml. of nitric acid per 100 ml., dry at 120° to 130° and weigh. Wt. of yellow precipitate $\times 0\cdot0376$ = wt. of orthophosphate as P_2O_5 .—R. M. Hitchens and M. S. McCauley, *J. Amer. pharm. Ass.*, 1936, 990.

Calcii Glycerophosphas (B.P.C.). $\text{CaC}_3\text{H}_5(\text{OH})_2\text{PO}_4\cdot 2\text{H}_2\text{O}=246\cdot2$. Loses not more than 15% of its weight at 130° and then

contains not less than 98% of the anhydrous salt, determined by ignition to pyrophosphate. Yields not more than 1% of residue (glycerin, etc.) insoluble in dehydrated alcohol; limits of alkalinity or acidity, citrate and glycerin and minimum of glycerophosphate are prescribed. The *N.F. VII* allows a loss of only 10% at 130° and is then of the same strength; assayed by precipitation of the calcium as oxalate in acetic acid solution and subsequent ignition to oxide. Glycérophosphate de Calcium, *Fr. Cx.* 1937, loses at 150° for 4 hours, not more than 15% moisture. The dried salt yields on incineration not less than 58% of pyrophosphate, contains by titration with N/10 sulphuric acid not less than 90% of the anhydrous substance, and by precipitation with magnesia mixture contains not less than 14.2% of phosphorus. Calcium glycerinophosphoricum, *P.G. VI*, contains not less than 84% of anhydrous calcium glycerophosphate, by titration with N/1 hydrochloric acid to methyl orange, addition of phenolphthalein and titration with N/1 potash; the two titrations should be equal. Calcium glycerinophosphoricum, *P. Helv. V*, contains not more than 16% of moisture, not less than 84% of $C_3H_7O_6PCa$, determined by dissolving in normal hydrochloric acid and titrating back with sodium hydroxide to methyl orange, and from 50.6 to 55.5% of ash on ignition.

Ferri Glycerophosphas (*B.P.C. Supp. IV*). Assayed for Fe content by the method of the *B.P.* for Ferri et Ammonii Citras, contains from 13 to 16% of Fe. Residue on ignition, not less than 42%. Ferri Glycerophosphas, *N.F. VII*, loses not more than 10% at 130° and the dried substance contains not less than 17% of Fe, equivalent to not less than 95% of $Fe_2(C_3H_7O_6P)_3$; in assaying, sodium bicarbonate is added to the acid mixture with potassium iodide.

Magnesii Glycerophosphas (*B.P.C.*).

$MgC_3H_5(OH)_2PO_4 \cdot 2H_2O = 230.4$. Loses not more than 16% at 130°, and then contains not less than 97% of $C_3H_7O_6PMg$, as estimated by weight of the ignited residue of pyrophosphate. Similar limit tests to those for the calcium salt are described.

Mangani Glycerophosphas (*B.P.C.*). $MnC_3H_5(OH)_2PO_4 = 225.0$. By calculation from the weight of the ignited residue the substance dried at 130° contains not less than 97%. Loss at 130° not more than 5%. Tests for limit of citrate, glycerin, alkalinity or acidity, and minimum of glycerophosphate are included. Mangani Glycerophosphas, *N.F. VII*, loses not more than 10% at 110°, and then contains not less than 98% of $MnC_3H_5(OH)_2PO_4$ when assayed by precipitation with dibasic ammonium phosphate in alkaline solution and ignition to $Mn_2P_2O_7$.

Assay. (*N.F. VII*.) Accurately weigh approximately 1.0 g., previously heated to constant weight, and dissolve in 1.5 ml. of nitric acid and 5 ml. of warm distilled water. Dilute to 125 ml., add 2.0 g. of dibasic ammonium phosphate, and heat to boiling; add a few drops of methyl red indicator and add strong ammonia solution drop by drop until alkaline, and then add 2.0 ml. excess. Allow to stand 2 hours at room temperature. Filter on to a Gooch

crucible and wash with a dilute solution of ammonia (1 in 100). Dry at 110° and ignite at a bright red heat. Each g. of $Mn_2P_2O_7$ is equivalent to 1.5855 g. of $MnC_4H_4(OH)_2PO_4$.

Potassii Glycerophosphas Liquidus (*B.P.C. Supp. IV*). Determined by the same methods as Sodii Glycerophosphas, it complies with the same limits for free alkali, free phosphate and glycerin and contains 48 to 52% *w/w* of $C_3H_7O_6PK_2 \cdot 3H_2O$. Sp. gr., 1.34 to 1.40.

Sodii Glycerophosphas (*B.P.C.*). $C_3H_7O_6PNa_2 \cdot 5\frac{1}{2}H_2O = 315.2$. Contains not less than 98% and not more than the equivalent of 102% of the pure substance with free alkali limit (as Na_2CO_3) of 0.5% and a free phosphate limit (as P_2O_5) of 0.5%. Assayed by the method of the *B.P.C.* by titration with normal hydrochloric acid using bromocresol green as indicator, less the sum of the readings for free alkali and free phosphate, these being obtained by titration with normal hydrochloric acid to thymol blue (free alkali) and subsequent addition of neutralised calcium chloride solution, boiling, and further titration of the cooled liquid with normal sodium hydroxide to thymol blue (free phosphate). The *N.F. VII* substance contains 68 to 74% of the anhydrous salt, as shown by titration with hydrochloric acid to methyl orange. Glycerophosphate de Sodium Cristallisé, *Fr. Cx.* 1937, contains 5 molecules of water of crystallisation; by titration with *N/10* sulphuric acid to helianthin it contains not less than 66% of the anhydrous salt and leaves 42% of residue on ignition.

Sodii Glycerophosphas Liquidus (*B.P.C.*). A solution of sp. gr. 1.28 to 1.32 containing 48 to 52% by weight of $C_3H_7O_6PNa_2 \cdot 5\frac{1}{2}H_2O$; free alkali (as Na_2CO_3) and free phosphate (as P_2O_5) limits, 0.5%. Assayed by the same process as for Sodii Glycerophosphas. Limit of free glycerin, determined by shaking with four volumes of dehydrated alcohol and one part of recently ignited calcium sulphate, filtering and evaporating the filtrate and alcoholic washings, and drying at 70° for one hour, 2%. Refractive index, 1.395 to 1.405.

ACIDUM HYDRIODICUM

(WITH METALLIC IODIDES)

Acidum Hydriodicum Dilutum (*B.P.C.*). Contains 9.8 to 10.2% *w/w* of HI, replacing the limits of the *B.P.* '14, approximately 9.7 to 10.2%, and a sulphate limit is included. Assayed by addition of excess silver nitrate solution and titration with ammonium thiocyanate. The *U.S.P. XII* acid contains from 9.5 to 10.5% *w/v* of HI and from 0.6 to 1.0% *w/v* of H_3PO_2 . Hypophosphorous acid is determined, after oxidation with hydrogen peroxide and volatilisation of the iodine, by precipitation with magnesia mixture and ignition to pyrophosphate. Tests for free iodine and limit of hydrochloric acid are included.

Syrupus Acidi Hydriodici (U.S.P. XII). Contains 1.3 to 1.5% *w/v* of HI.

Ammonii Iodidum (B.P.C.). $\text{NH}_4\text{I} = 145.0$. The salt dried at 100° contains 98%, 5% loss on drying at 100° being allowed. Assayed by the B.P. process for potassium iodide by titration with potassium iodate in presence of hydrochloric acid. The N.F. VII dries the salt for 6 hours at 110° , the limit of moisture and the standard then being the same, the use of 1% of ammonium hypophosphite as a stabilising agent is allowed. Assayed by digestion on a water-bath until the precipitate with standard silver nitrate solution is yellow, cooling and titrating with standard ammonium thiocyanate.

Calcii Iodidum (B.P.C.). $\text{CaI}_2 = 293.9$. Determined by iodide content it contains not less than 80% of CaI_2 .

Syrupus Ferri Iodidi (B.P.). Contains 4.75 to 5.25% *w/w* of FeI_2 . The preparation of the N.F. VII contains 6.5 to 7.5% *w/v* of FeI_2 , equivalent to approximately 5% *w/w* of FeI_2 .

Potassii Iodidum (B.P.). $\text{KI} = 166.0$. Loses not more than 1% at 110° and then contains 99% of KI when determined by titration with M/20 potassium iodate in the presence of not less than 40% of hydrochloric acid. The U.S.P. XII salt complies with the same standards and is assayed similarly, but the titration mixture is allowed finally to stand 5 minutes before adjusting the end-point. The Fr. Cx. 1937 requires a purity of 99% on the dried salt and alkalinity not in excess of 0.8% of KOH.

Assay. The following assay is recommended by the Sub-Committee on Inorganic Chemicals of the Committee on General Chemistry: Dissolve about 0.7 g., accurately weighed, in 50 ml. of water, add 15 ml. of hydrochloric acid and 6 ml. of solution of potassium cyanide, and titrate with M/20 potassium iodate until the dark-brown solution, which is formed, becomes pale yellow, then add 5 ml. of mucilage of starch and continue the titration slowly until the liquid becomes colourless. Each ml. of M/20 potassium iodate is equivalent to 0.0166 g. of KI. (*British Pharmacopœia Commission Report*, No. 14, September 1939.)

Alternative Assay Process. The following assay process based on the formation of iodine cyanide is preferable to that of the B.P. The potassium iodide solution, containing about 0.5 g. in 50 ml. of water, is strongly acidified with hydrochloric acid and treated with potassium cyanide solution. The mixture is then titrated with M/40 potassium iodate, using starch mucilage as indicator, until the last trace of blue or reddish violet colour has disappeared. Each millilitre of M/40 potassium iodate is equivalent to 0.0083 g. of KI.

This method can also be applied to solutions containing iodine and potassium iodide. 5 ml. of approximately N/10 iodine is diluted to about 100 ml. and treated with 50 ml. of 2N hydrochloric acid and 5 ml. of 10% potassium cyanide. The mixture is then titrated with M/40 potassium iodate until the colour disappears. Excess of potassium iodide is then added and the liberated iodine titrated with thiosulphate. If the two titrations are *a* and *b* ml. respectively, the potassium iodide is given by the expression

$$\frac{166.02 (5a - 2b)}{200} \text{ g. per litre,}$$

and the iodine is given by the expression

$$\frac{126.92 (2b - 3a)}{100} \text{ g. per litre.}$$

—A. D. Mitchell, Lecture to Institute of Chemistry, 19/10/1934.

Tabellæ Potassii Iodidi (N.F. VII). Tablets of 0.3 g. or more contain 94 to 106%, and tablets of less than 0.3 g. contain 92.5 to 107.5%, of the labelled amount of potassium iodide, including all tolerances. Assayed by titration with M/50 potassium iodate.

Sodii Iodidum (B.P.). $\text{NaI} = 149.9$. Loses not more than 5% at 110° and then contains 99% of the pure salt. It is assayed by titration with M/20 potassium iodate in the presence of hydrochloric acid. The U.S.P. XII allows 5% of water loss at 120° and the salt should then be of 99% purity, assayed by titration with

potassium iodate, the final adjustment of the end-point being made after allowing the titration mixture to stand for 5 minutes. The *Fr. Cx.* 1937 requires the dried salt to contain 98% of NaI and to possess alkalinity not more than 0.6% as NaOH by titration to phenolphthalein.

Strontii Iodidum (B.P.C.). $\text{SrI}_2 \cdot 6\text{H}_2\text{O} = 449.6$. Titrated with standard iodate solution, it contains 99% of the hydrated substance.

Zinci Iodidum (B.P.C.). $\text{ZnI}_2 = 319.2$. Contains not less than 98% of the pure salt, assayed for its iodide content. The *N.F. VII* salt is of the same strength after losing not more than 5% over sulphuric acid for 24 hours.

Calcii Iodobehenas (U.S.P. XII). Loses not more than 2% at 100°, and then contains not less than 23.5% of I; assayed by extraction with water of the residue obtained on ignition with potassium carbonate, addition of potassium permanganate to a pink coloration to the liquid on a water-bath, decolorising with alcohol, cooling and filtering, followed by titration, with sodium thiosulphate, of the iodine liberated in an aliquot part by potassium iodide and sulphuric acid.

Iodised Salt.

DETERMINATION OF IODINE. 100 g. of the salt is dissolved in water, the solution diluted to 500 ml. and filtered. To 200 ml. of the filtrate, made faintly acid to methyl orange, is added 1 ml. of bromine water. The solution is boiled until salt begins to separate, pumice being added to prevent bumping. Sufficient water is added to dissolve the precipitate, then 2 ml. of N/1 hydrochloric acid and 0.2 g. of potassium iodide, and the liberated iodine titrated with N/500 sodium thiosulphate. Unless the iodide is oxidised to iodate in practically neutral solution the reaction is incomplete in the presence of excess of sodium chloride.—R. L. Andrew and J. L. Mandeno, *Analyst*, 1935, 801.

Iodide is lost when the iodised salt is stored in cardboard containers owing to absorption by the cardboard; there is no loss to the atmosphere. The loss may amount to 50% during 6 months.—R. C. Andrews, *Analyst*, 1938, 180.

ACIDUM HYDROBROMICUM

(WITH METALLIC BROMIDES)

Acidum Hydrobromicum (B.P.C.). Contains 34 to 35% w/w of HBr and has sp. gr. of 1.303 to 1.314. 290 g. with 710 g. of water produces an acid of approximately the same strength as Acidum Hydrobromicum Dilutum, *B.P.* '32, containing 9.8 to 10.2% of HBr and with a sp. gr. of 1.072 to 1.075; a limit of chlorine equivalent to about 0.35% w/w of HCl is therefore included. Acidity estimated with standard sodium hydroxide to methyl orange.

Ammonii Bromidum (B.P.C.). $\text{NH}_4\text{Br} = 97.96$. Loses not more than 1% at 100° and then contains 99% of the pure salt. The *B.P.* '14 required only 98% purity with the same moisture allowance. Estimated by total halogen content, with chloride and bromate limits specified. The *N.F. VII* salt contains 99% of NH_4Br , after drying 24 hours over sulphuric acid. Bromure d'Ammonium, *Fr. Cx.* 1937, dried at 100°, contains, when assayed gravimetrically, not less than 98% of NH_4Br . Ammonium bromatum, *P.G. VI*, dried at 100°, contains at least 98.8% of NH_4Br .

Calcii Bromidum (*B.P.C. Supp. IV*). $\text{CaBr}_2 \cdot 2\text{H}_2\text{O} = 235.9$. Contains 95 to 102% of the pure salt, assayed as Potassii Bromidum. Calcii Bromidum, *N.F. VII*, contains 84 to 94% of the anhydrous salt, which is equivalent to approximately 99 to 111% of the hydrated compound; assayed for calcium content by precipitation with ammonium oxalate and titration of the precipitate in acid mixture with N/10 potassium permanganate. The *Fr. Cx.* 1937 substance, assayed by weight of silver bromide, contains not less than 80% CaBr_2 .

Potassii Bromidum (*B.P.*). $\text{KBr} = 119.0$. Loses not more than 1% at 110° and then contains 99% of the pure salt. Assayed by addition of excess silver nitrate and back titration with ammonium thiocyanate. It is official in the *U.S.P. XII*. Bromure de Potassium, *Fr. Cx.* 1937, by weight of silver bromide, yields 99% of KBr on the dried substance.

Sodii Bromidum (*B.P.*). $\text{NaBr} = 102.9$. Loss on drying at 110° not more than 5% and then contains 99% of the pure salt, assayed for bromide content. The *U.S.P. XII* requires the substance dried at 110° to contain 99% of NaBr ; moisture, not more than 1%. Bromure de Sodium, *Fr. Cx.* 1937, loses not more than 2% at 100° and then contains not less than 97% of pure salt.

Tabellæ Sodii Bromidi (*N.F. VII*). Contain 92.5 to 107.5% of the labelled amount of sodium bromide, including all tolerances. Comply with a limit test for chloride. Assayed by adding excess N/10 silver nitrate and nitric acid and titrating with N/10 ammonium thiocyanate.

Tabellæ Bromidum Trium (*N.F. VII*). Contain bromine equivalent to 70 to 81% of the labelled amounts of total bromides (equal proportions of ammonium, potassium and sodium bromides), and contain 30.8 to 35.8% of ammonium bromide, including all tolerances in both cases. Assayed for total bromine by dissolving in water, adding excess N/10 silver nitrate and titrating with N/10 ammonium thiocyanate in the presence of nitric acid. Assayed for ammonium bromide by dissolving in water, adding sodium hydroxide solution, distilling into N/2 sulphuric acid and titrating the excess acid with N/10 sodium hydroxide using methyl red indicator.

Strontii Bromidum (*B.P.C.*). $\text{SrBr}_2 \cdot 6\text{H}_2\text{O} = 355.6$. Assayed by the same method as Potassii Bromidum. It should contain not less than 97% of the pure substance. The *N.F. VII* salt should contain not less than 98% of the hexahydrate; loss at 200°, not more than 32%. Bromure de Strontium, *Fr. Cx.* 1937, contains not less than 69.5% of the anhydrous salt.

Zinci Bromidum (*B.P.C. Supp. IV*). $\text{ZnBr}_2 = 225.2$. Contains not less than 95% of ZnBr_2 . Assayed by the *B.P.* process for Zinci Sulphas as follows:—Dissolve about 0.3 g. in 120 ml. of water, acidify with a drop of dilute sulphuric acid, add 25 ml. of mercuric ammonium thiocyanate solution, allow to stand for 5 minutes, stir well and stand for a further hour; filter on a small suction filter and wash with five quantities of 10 ml. of mercuric ammonium thiocyanate solution, diluted with water (1 : 50). To the precipitate and filter in a stoppered bottle add 5 ml. of water and 40 ml. of hydrochloric acid and titrate immediately with M/5 potassium iodate, using 5 ml. of chloroform as indicator.

ACIDUM HYDROCHLORICUM

(with METALLIC CHLORIDES)

Acidum Hydrochloricum (B.P.). Contains from 31 to 33% by weight of HCl; sp. gr., 1.156 to 1.168. Acidum Hydrochloricum Dilutum contains from 9.5 to 10.5% w/w of HCl and has a sp. gr. of 1.045 to 1.052. The stronger acid of the *U.S.P. XII*, having a sp. gr. at 25° of about 1.18, should contain 35 to 38% w/w of HCl. The dilute acid, sp. gr. 1.046 at 25°, contains 9.5 to 10.5% w/v of HCl. *Acide Chlorhydrique Officinal, Fr. Cx.* 1937, contains not less than 35.5% of HCl. Acidum hydrochloricum fortius and Acidum hydrochloricum dilutum, *P. Helv. V*, should contain respectively 24.9 to 25.1% and 9.9 to 10.1% w/w of HCl. Acidum hydrochloricum, *P.G. VI*, contains 24.8 to 25.2% of HCl and Acidum hydrochloricum dilutum 12.4 to 12.6%.

The British Standards Institution has published British Standard Density-Composition Tables for Aqueous Solutions of Hydrochloric Acid (*B.S.S. No. 976—1941*) giving the concentration in g. of HCl per 100 g. and in g. of HCl per 1000 ml. corresponding to densities of 1 to 1.161 for each 5° over the range of 0° to 40°. The tables are designed for use in conjunction with British Standard Density Hydrometers.

Ammonii Chloridum (B.P.). $\text{NH}_4\text{Cl} = 53.5$. Loses not more than 1% when dried in a vacuum desiccator over sulphuric acid for 24 hours and should then contain 99.5% of NH_4Cl . Residue on volatilisation not more than 0.1%. Assayed on the chloride content by addition of excess standard silver nitrate to a solution acidified with nitric acid and adjustment to volume, followed by titration of an aliquot part with ammonium thiocyanate using ferric ammonium sulphate as indicator. The salt is official in the *U.S.P. XII* and is of the same strength. Chlorure d'Ammonium, *Fr. Cx.* 1937, determined gravimetrically, contains not less than 99% of NH_4Cl .

Improved Method of Assay. Dissolve about 9.14 g., accurately weighed, in water, dilute to 50 ml., add 8 to 10 drops of a 0.1% aqueous solution of sodium fluorescein, and titrate with N/10 silver nitrate solution, shaking after each addition. The end-point is the formation of a pronounced pink tint, and is not affected by adsorption as in the Volhard Method. The method is rapid and gives more accurate results than the official method.—T. L. Bowyer, *Chem. & Drugg.*, ii/1939, 343.

Tabellæ Ammonii Chloridi (N.F. VII). Contain 94 to 106% of the labelled amount of ammonium chloride for tablets of 0.3 g. or more and 92.5 to 107.5% for tablets of less than 0.3 g., including all tolerances. Assayed by dissolving a weighed quantity of powdered tablets in water, adding excess N/10 silver nitrate, filtering and titrating with N/10 ammonium thiocyanate.

Calcii Chloridum (B.P.). $\text{CaCl}_2 = 111.0$. The salt should be of 98% purity after drying at 200°, when the loss should be not more than 10%. Assayed by titration with standard silver nitrate using potassium chromate as indicator.

Calcii Chloridum Hydratum (B.P. Add. I). $\text{CaCl}_2 \cdot 6\text{H}_2\text{O} = 219.1$. Contains 98% to the equivalent of 102% of the hydrated salt by titration with silver nitrate. Calcii Chloridum, *U.S.P. XII*, the hydrated salt with 2 molecules of water, contains 75 to 81%

of CaCl_2 . Determined by precipitation with excess standard oxalic acid in ammoniacal solution followed by titration of the acidified filtrate with potassium permanganate.

British Standard Density-Composition Tables for Aqueous Solutions of Sodium Chloride and of Calcium Chloride (*B.S.S.* No. 823—1938) give the concentration in g. of CaCl_2 per 100 g. and in g. of CaCl_2 per 1000 ml. corresponding to densities of 1.00 to 1.39 for each 5° over the range of 10° to 40° . The tables are designed for use in conjunction with British Standard Density Hydrometers.

Magnesi Chloridum (B.P.C.). $\text{MgCl}_2 \cdot 6\text{H}_2\text{O} = 203.3$. 2 g. yields a clear solution in 10 ml. of alcohol (85%); CaSO_4 limit, 4%, determined by dissolving in 25 parts of 20% sulphuric acid, adding 50 parts of 95% alcohol and allowing to stand overnight.

Potassii Chloridum (B.P.C.). $\text{KCl} = 74.55$. Titrated by the method for Sodii Chloridum, the substance dried at 130° contains 99.5% of KCl . Loses not more than 1.0% at 130° . Potassii Chloridum, *U.S.P. XII*, loses not more than 1% at 110° , and then contains 99% of KCl .

Detection of Manganese in Presence of Chlorides. Dissolve 25 g. of sample in 100 ml. of hot water, add 5 ml. of hydrochloric acid and boil. If iron is absent, add 0.1 g. of ferric ammonium sulphate. Then make the solution just alkaline with 20 per cent. sodium hydroxide solution and continue boiling to coagulate the ferric hydroxide. Collect the precipitate and dissolve it by adding two 10-ml. portions of 10% sulphuric acid, collecting the solution in a 20-ml. conical flask. Add 2 g. of phosphoric acid and 0.5 g. of potassium periodate and boil for twenty minutes. Compare the resulting coloured solution with standard permanganate solutions.—R. Gilbert, *Analyst*, 1941, 450.

Tabellæ Potassii Chloridi (U.S.P. XII). Contain 95 to 105% of the labelled amount of KCl , including all tolerances. Comply with tests for calcium, magnesium and sodium. Assayed by dissolving in water, adding excess N/10 silver nitrate and back titration with N/10 ammonium thiocyanate.

Sodii Chloridum (B.P.). $\text{NaCl} = 58.45$. Loses not more than 1.0% at 130° and then contains 99.5% of the pure salt. A test for the absence of iodides and bromides, by the addition of chloroform and chlorine solution to the alcohol-soluble matter dissolved in water, is included. The *U.S.P. XII* salt contains 99.5% of NaCl after drying at 110° . 5 g. in 50 ml. of water requires not more than 0.1 ml. N/50 sodium hydroxide to produce a blue colour, or not more than 0.2 ml. of N/50 hydrochloric acid to produce a yellow colour, with bromothymol blue. The *Fr. Cx.* 1937 requires a purity of 99% on the dried substance.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined table salt, dairy salt, as fine-grained crystalline salt containing, on a water-free basis, not more than 1.4% of calcium sulphate, not more than 0.5% of calcium and magnesium chlorides, nor more than 0.1% of matter insoluble in water. Pending further announcement, no exception is taken to content of anhydrous calcium sulphate (anhydride) in excess of 0.1% provided the total calcium sulphate content does not exceed 1.4%.—*S.R.A., F.D. No. 2, Rev. 5, Nov. 1936.*

British Standard Density-Composition Tables for Aqueous Solutions of Sodium Chloride and of Calcium Chloride (*B.S.S.* No. 823—1938), designed for use in conjunction with British Standard Hydrometers, give the concentration in g. of NaCl per 100 g. and in g. of NaCl per 1000 ml. corresponding to densities of 1.00 to 1.200, for each 5° over the range of 0° to 40° .

Liquor Sodæ Chlorinatæ Chirurgicæ (B.P.). Contains 0.5 to 0.55% w/v of available chlorine, determined by interaction with potassium iodide and titration with N/10 sodium thiosulphate.

Chlorine in Industry.

This substance is encountered in industry in bleach and alkali works and is also used largely from cylinders, which are apt to leak or to stick, and it is in attending to these two troubles that there is the greatest risk of an accident. There is no risk of delayed action and on account of its lower solubility it is about 20 times as toxic as hydrochloric acid, which is much more rapidly absorbed into the system. It is a greenish-yellow gas with a distinctive odour, which can be detected in a concentration of about 3 to 5 parts per million. A concentration of 1 in 1000 is rapidly fatal and the greatest possible concentration for prolonged exposure would appear to vary between 1 and 10 parts per million. Workers appear to become acclimatised to the vapours of chlorine and not to develop hypersensitivity.

Treatment. If there is any risk of exposure to a dangerous concentration the patient should be rested for 24 hours and kept warm. As a rule drugs are not required but if pulmonary complications set in these should be treated accordingly. In mild cases ordinary expectorants may be useful when acute symptoms have abated.

Detection and Determination. Chlorine may be detected by the development of a blue colour with aniline acetate or a yellow colour with *o*-tolidine and also by the liberation of iodine from starch-potassium iodide solution of paper. For its determination in the atmosphere the most satisfactory method is to draw the suspected air through a solution containing 0.1% of *o*-tolidine in a solution containing 10% of concentrated hydrochloric acid and comparing the yellow colour developed with a standard dichromate solution or a solution of the reagent to which a known amount of chlorine has been added.—(*Toxic Gases in Industry*, No. 10, D.S.I.R.)

Zinci Chloridum (B.P.). $\text{ZnCl}_2 = 136.3$. Assayed by precipitation of the solution acidified with sulphuric acid with mercuric ammonium thiocyanate, and titration in hydrochloric acid of the washed precipitate with standard potassium iodate, using chloroform as indicator, it contains zinc equivalent to 95% of ZnCl_2 . The U.S.P. XII salt is of the same strength, determined by precipitation as carbonate and ignition to oxide.

Perchloric Acid, HClO_4 . Available commercially containing 60% *w/w*, with sp. gr. 1.54. A powerful acid and oxidising agent. As a reagent for potassium, qualitatively and quantitatively, it has largely replaced the chloroplatinate method.

Mercurimetric Determination of Halides. The method is based on the precipitation of the mercurous halide when a solution of mercurous nitrate is added to that of the halide. Approximately N/10 mercurous nitrate is prepared by dissolving about 30 g. of the salt in a litre of N/5 nitric acid. The solution when kept in contact with a globule of mercury is stable for several months. The solution is standardised against N/10 sodium chloride, using ferric thiocyanate as indicator. 1 ml. of N/20 ammonium thiocyanate and 2 ml. of a concentrated solution of ferric nitrate are added to 25 ml. of N/10 sodium chloride and the solution titrated with the mercurous nitrate solution until disappearance of the red colour. To correct for the volume of mercurous nitrate

solution required by the indicator, a blank titration is made with an equal volume of the indicator and the volume obtained is subtracted from that obtained in the standardisation. The determination of chlorides and bromides is carried out by the above method. For the determination of iodides, 25 ml. of an approximately N/10 solution of the iodide is added to 50 ml. of N/10 mercurous nitrate, the solution is filtered and the precipitate washed several times with water acidified with a little dilute nitric acid. The excess of mercurous nitrate in the filtrate is determined by oxidation to mercuric nitrate and titration with ammonium thiocyanate. The filtrate is treated with 2 ml. of dilute nitric acid and sufficient saturated solution of potassium permanganate to produce a pink coloration, the excess of permanganate is removed with a little ferrous sulphate solution and then the resulting solution titrated with N/10 ammonium thiocyanate.—M. Chitchigol, per *Quart. J. Pharm.*, 1937, 89.

Detection of Halides in Presence of Cyanides. Excess of 5% mercurous nitrate solution is added to the precipitate obtained with silver nitrate and nitric acid; silver cyanide becomes black in colour and then dissolves. Any silver halides present are unacted upon and can be identified.—G. A. D. Haslewood, *J. chem. Soc.*, 1936, 1049.

Detection of Halides in Presence of Thiocyanates. To 10 ml. of sample add 1 ml. of carbon tetrachloride and 0.5 g. of potassium persulphate. If iodide is present the iodine liberated colours the carbon tetrachloride violet. The aqueous layer is separated and neutralised with 2N sodium carbonate and an excess of 15 ml. added, and the mixture evaporated to dryness. The residue is dissolved in 10 ml. of water and the iodine completely removed by warming with dilute nitric acid and potassium persulphate and extracting with carbon tetrachloride. To the cold iodine-free solution add 4 ml. of nitric acid and 1 ml. of carbon tetrachloride. A yellow coloration of the solvent which persists after allowing to stand for one minute with occasional stirring indicates presence of bromine. The aqueous layer is again separated and boiled for 1 minute with excess of potassium permanganate to remove bromide, sulphate is removed with barium nitrate and the filtrate is tested for chloride with silver nitrate.—G. B. and L. K. Heisig, *Industr. Engng Chem. (anal. Edn.)*, 1935, 249.

Determination of Cyanide, Chloride and Iodide Mixtures. Cyanide is determined by a direct titration with silver nitrate without any indicator, the end-point being the appearance of a permanent opalescence which is best seen by placing a black surface under the titration vessel. End-points are obtained without difficulty at so low a concentration as N/50. A second portion of the sample is boiled for 15 minutes with a slight excess of potassium bitartrate to eliminate the cyanide and the iodide is determined by titration of the cooled solution with silver nitrate, using rose bengal as adsorption indicator. The liquid is decanted through a filter, the precipitate washed with very dilute nitric acid and the chloride determined by titrating the filtrate with silver nitrate using phenosafranine as indicator. Tartrazine can be used instead of phenosafranine; both indicators give satisfactory results for the titration in nitric acid solution up to an acid concentration of about normal, but phenosafranine is preferable for work at extreme (N/100) dilution. Mixtures of cyanide and chloride or bromide may be determined after direct titration of the cyanide as above by adding nitric acid and excess of silver nitrate, filtering off the precipitate, and back-titrating the excess of silver nitrate with potassium bromide using either phenosafranine or tartrazine as indicator. The method is also applicable to the determination of thallous-thallic halides for which Volhard's method is unsatisfactory. The sample is reduced with a 2% zinc amalgam and the reduced solution is run from a burette into a known volume of silver nitrate solution using tartrazine as indicator.—A. J. Berry, *Analyst*, 1936, 315.

ACIDUM HYDROCYANICUM

Acidum Hydrocyanicum Dilutum (B.P.). Contains 1.9 to 2.1% w/w of HCN. **Acidum Hydrocyanicum Fortius (B.P.C. '34)** contains 3.8 to 4.2% of HCN, and the dilute acid of the International Agreement, 2%. Determined by titration with silver nitrate in ammoniacal solution using potassium iodide as

indicator. Acidum Hydrocyanicum Dilutum, *N.F. VII*, contains 1.9 to 2.1% *w/w* of HCN, and not more than 0.1% of HCl. Determined by titration with silver nitrate in alkaline solution, using potassium iodide as indicator, and titration of total halide by addition of excess silver nitrate, filtration and titration with ammonium thiocyanate, the difference between the two titrations being calculated as HCl.

Determination of hydrocyanic acid.—C. E. Corfield and C. J. Eastland, *Yearb. Pharm.*, 1921, 391.

Phthalin Method of Estimation. The most suitable method for the estimation of traces of hydrocyanic acid in cyanogenetic plants is that depending on the oxidation of a phthalin to a coloured phthalein. Using *o*-cresolphthalin, 1 part of hydrocyanic acid in 100 million can be detected with certainty. Reagents required include:—*Copper Reagent*.—150 mg. of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in 100 ml. of water; *Sodium Sulphite Reagent*.—5 g. of anhydrous sodium sulphite and 0.224 g. of triethanolamine hydrochloride in 100 ml. of water; *Cresol Red Reagent*.—50 mg. of cresol red in 125 ml. of alcohol made up to 250 ml. with water. Five ml. of this solution are treated with 2 ml. of $\text{N}/2$ sodium hydroxide solution and 2 ml. of the copper sulphate and triethanolamine hydrochloride reagent and made up to 200 ml.; *Copper Sulphate and Triethanolamine Hydrochloride Reagent*.—300 mg. of copper sulphate and 896 mg. of triethanolamine hydrochloride in 100 ml. of water. *Method*.—The solution, containing 0.01 to 0.1 mg. of hydrocyanic acid, is treated in a graduated 50 ml. flask with $\text{N}/2$ sodium hydroxide so that 1.5 ml. of $\text{N}/2$ NaOH is finally present; the volume is adjusted to 45 ml. and the flask cooled. The temperature is taken, 1 ml. of cresolphthalin reagent (40 mg. of *o*-cresolphthalin in 10 ml. of alcohol made up to 20 ml. with water) added, and the whole mixed. Then 1 ml. of copper reagent is quickly added, the flask stoppered and shaken; after exactly 5 minutes (measured by stopwatch) 2 ml. of the sodium sulphite reagent are rapidly added to stop the reaction, the contents of the flask mixed, made up to 50 ml. and transferred to the colorimeter, where the reading is taken at the end of 5 minutes. Comparisons are made with the alkaline mixture of cresol red, copper sulphate and triethanolamine hydrochloride, and a calibration curve of concentration against colorimeter reading is plotted. Temperature has a noticeable effect on colour development and the estimation should be made within 1° of the temperature to which the curve relates. Temperature control is necessary only during colour development and is not required after addition of the reducing agent.—R. I. Nicholson, *Analyst*, 1941, 189.

Determination in *Prunus Serotina*. From 15 to 25 g. of the powdered bark, accurately weighed, are allowed to stand with 200 ml. of water at ordinary temperature in a closed round-bottomed flask of 1 litre capacity and fitted with a side-arm for 24 hours. It is then steam-distilled into 1% sodium hydroxide solution for 1 hour. The distillate is acidified with hydrochloric acid, and, after the addition of excess of sodium bicarbonate, titrated with $\text{N}/20$ iodine.—Fordos and Gellis, per *Aust. J. Pharm.*, 1940, 570.

Delicate Test for Hydrocyanic Acid. A few drops of phenolphthalin solution made alkaline with sodium hydroxide added to liquid to be tested. If red colour be produced on adding cupric sulphate solution 1 in 2000 (due to oxidation into phenolphthalein) hydrocyanic acid is proved to be present. Phenolphthalin is made by reducing phenolphthalein with zinc in alkaline solution.—*Pharm. J.*, 1/1905, 721.

Place 1 drop of 1:5 ammonia dilution on a microscopic slide and invert over tube containing the solution to be tested, together with a few drops of sulphuric acid. After a few minutes remove slide and place under microscope: on the addition of 1 drop of alloxan solution (made by boiling 0.1 g. of uric acid with 0.2 ml. of nitric acid and 0.2 ml. of water and diluting to 5 ml.) crystals of oxaluramide begin to form in a few minutes if the test solution contains a cyanide. Substitution of pyridine for ammonia renders test far more delicate so that a few drops of a solution containing 0.01 g. HCN per litre gives positive results.—per *Yearb. Pharm.*, 1927, 168.

Detection of Inhaled Hydrocyanic Acid. 250 ml. of blood from the lungs is steam-distilled until 15 ml. of distillate has been collected. The

following tests are made on separate 5 ml. quantities of distillate. *Prussian Blue Test.* Make alkaline with 2 to 3 drops of 5% sodium hydroxide solution and add 2 drops of 5% ferrous sulphate solution and 1 drop of 3% ferric chloride solution. Allow to stand for 2 minutes, heat gently and add just sufficient dilute hydrochloric acid to clear. In the presence of traces of cyanide a blue precipitate may settle out only after standing overnight. *Sulphocyanide Test.* Heat with 1 drop of ammonium sulphide solution for 15 minutes on a water-bath. Add dilute nitric acid until the yellow colour is just destroyed and then ferric alum solution drop by drop.—G. D. Elsdon and J. R. Stubbs, *Analyst*, 1937, 540.

Sometimes both the above tests fail and the following may be tried. Collect the distillate from blood or lung tissue in a conical flask, fix sulphur compounds with a few drops of lead acetate solution and make faintly acid with sulphuric acid. Place a drop of approximately N/10 silver nitrate on a microscope slide, invert over the mouth of the flask, and stand in a warm place for at least 30 minutes. Microscopic examination may reveal characteristic crystals of silver cyanide.—G. Roche Lynch, *ibid.*

As a bactericide (fumigant in ship disinfection) hydrocyanic acid is too weak to affect pathogenic germs. It has no measurable carbolic acid co-efficient. *Less than 0.02.*—W. C. Reynolds, *Lancet*, ii/1922, 834. Its danger.—*Pharm. J.*, i/1923, 300. It destroys rats, fleas, etc. It has no ill effects on dry grain, but moist food, e.g., butter, milk, etc., is liable to absorb the gas.

Insecticides. The specification of the Association of British Insecticide Manufacturers (Bulletin No. 82, Ministry of Agriculture and Fisheries) requires *Potassium Cyanide* to contain not less than 93% potassium cyanide; *Sodium Cyanide* to contain not less than 97% sodium cyanide; *Calcium Cyanide* to contain not less than 40% calcium cyanide. The strength of sodium cyanide is frequently expressed in terms of potassium cyanide; thus 97 to 98% sodium cyanide may be referred to as 129 to 130% cyanide.

Hydrogen Cyanide in Industry.

Hydrogen cyanide is extensively used in the fumigation of ships, flour mills, orchards, etc., and even rabbit burrows. It is also largely employed in gold extraction and in smaller amounts in other industries. In the last war it was tried as a war gas with indifferent success and it is doubtful whether its use would be repeated. For this purpose it was classed as a paralyzant. Hydrogen cyanide is sometimes formed in small quantities through the incomplete combustion of explosives. It is a colourless gas with a faint odour of bitter almonds, but can be noticed by some people by the dry taste at the back of the mouth. High concentrations are extremely rapid in their action, causing giddiness, headache and unconsciousness with convulsions. Its extreme rapidity of action is due to paralysis of the respiratory system, which prevents the use of oxygen by the tissues. One part in 500 is immediately fatal, whilst 1 part in 10,000 for an hour is very dangerous, and 1 part in 40,000 to 50,000 may cause symptoms after several hours' exposure. Milder symptoms of poisoning are irritation of the throat, headache, suffocation, nausea and giddiness.

Treatment. The patient should be removed immediately to fresh air and kept warm. If necessary, artificial respiration should be employed, using air mixed with 5 to 7% of carbon dioxide. Only partial success has so far attended the internal use of chemicals for neutralisation purposes.

Detection and Determination. Two methods are recommended. The benzidine-copper acetate method consists in soaking papers with a solution obtained by mixing 25 ml. of a freshly prepared solution of benzidine acetate (containing about 1%

of benzidine acetate) and 2 ml. of 3% cupric acetate solution. The papers are drained and nearly dried and air is drawn through them by means of a pump or aspirator, when a greyish-blue to a deep blue appears in the presence of hydrogen cyanide vapours. The depth and shade of colour may be compared with those of a standard chart and the amount of gas recorded. The Congo red-silver nitrate method depends on the use of freshly prepared papers, obtained by soaking in 0.05% Congo red solution, drying, subsequently soaking in 5% silver nitrate solution, and drying rapidly. The colour developed varies from a greyish-purple to a greyish-blue and by comparison with a standard chart the amount of gas in the atmosphere under examination may be determined.—(*Toxic Gases in Industry*, No. 2, D.S.I.R.)

Alkyl thiocyanates are of increasing use as insecticides, the following being found in commercial preparations. β -Butoxy-3-thiocyanodiethyl ether (Lethane 384), lauryl thiocyanate, 3-thiocyanopropylphenyl ether, trimethylenedithiocyanate, α -naphthyl isothiocyanate (Kessocide 95) and *m*-phenylene di-isothiocyanate. The first four appear to have a more paralysing action on cockroaches than the last two. Methods of analysis of preparations of normal aliphatic and aromatic thiocyanates are detailed based on a colorimetric procedure in terms of cyanogen. In the case of isothiocyanates, it is suggested that the most satisfactory method available for the quantitative determination is the utilisation of the same hydrolysis reaction used in the determination of normal thiocyanates and the subsequent determination of the primary amine.—W. E. Kemp, *Analyst*, 1939, 648.

Calcium Cyanide. Direct injection of rat harborages with calcium cyanide dust is simplicity itself. The dust is taken from a tightly covered can, in which it is marketed, and is poured into the container of a foot-pump type of duster, this container then being screwed into place. The rubber hose extending from the duster is inserted into small openings into harborages by a fumigator while another operates the pump. If the enclosed spaces to be treated are few or of limited extent, the whole operation might be carried on, even in the hold of a ship, without the wearing of gas masks by the fumigators. If, however, many harborages are to be treated or they are extensive, gas-mask protection is necessary. The material used, calcium cyanide, is at present manufactured in the United States under the trade-name Cyanogas. It is also manufactured in Germany, under the trade-name Calcyanide. Cyanogas is obtainable in flakes, granules, or as a dust. Calcyanide is at present obtainable only as a fine dust, although it is available abroad in the form of briquets, which are broken into a dust for use. Cyanogas is blue in colour, while Calcyanide is a light brown. Cyanogas contains from 40 to 50% of calcium cyanide, while Calcyanide contains from 80 to 85%. This is important to remember, since in interchanging these materials the Calcyanide must be used in approximately half the amounts of Cyanogas. For use in the foot-pump duster, the form of Cyanogas to be specified is the "A" dust.—*Publ. Hlth Rep., Wash.*, 1936, 139.

Aqua Laurocerasi (B.P.C.). Adjusted to contain 0.09 to 0.11% *w/v* of HCN and assayed by the method for Acidum Hydrocyanicum Dilutum. Aqua Laurocerasi I.A. and Aqua Amygdalæ Amaræ I.A. each contain 0.1% of HCN. The water of the *Fr. Cx.* 1937 should contain not more than 0.025% of free HCN and not less than 0.3% of benzoic aldehyde determined by weight of the separated phenylhydrazone. For medicinal use it contains 0.1% HCN, free and combined.

The bright green young *Prunus Laurocerasus* leaves were found to yield from two to four times the amount of hydrocyanic acid given by the older and more leathery brown leaves of cherry laurel. Adequate manuring caused increase in the amount of hydrocyanic acid contained.—D. H. Wester, *Pharm. J.*, 1/1904, 643.

ACIDUM HYPOPHOSPHOROSUM

Acidum Hypophosphorosum (B.P.C.). Contains 30 to 32% of H_3PO_2 . 323 g. with 677 g. of water yields an acid of approximately the same strength as Acidum Hypophosphorosum Dilutum, B.P., 9.8 to 10.2% w/w of H_3PO_2 . The U.S.P. XII acid is of the same strength as the B.P.C. acid.

Ammonii Hypophosphis (N.F. VII). $\text{NH}_4\text{H}_2\text{PO}_2 = 83.07$. Loses, over sulphuric acid for 24 hours, not more than 3% and then contains not less than 97.5% of $\text{NH}_4\text{H}_2\text{PO}_2$. Assayed by treatment with excess standard bromine solution in presence of sulphuric acid during 3 hours, addition of potassium iodide, and back titration with standard sodium thiosulphate; 1 ml. of N/10 bromine = 0.002076 g. of $\text{NH}_4\text{H}_2\text{PO}_2$.

Assay of Hypophosphites. About 0.7 g., accurately weighed, is dissolved in sufficient water to give 500 ml. To 50 ml. of the solution in a 250 ml. stoppered flask add 50 ml. of N/10 bromine and 20 ml. of dilute sulphuric acid; stopper the flask, shake well and allow to stand for 2 hours. Add 10 ml. of 20% w/v potassium iodide solution, shake, and titrate with N/10 sodium thiosulphate. Carry out a blank determination. 4 atoms of bromine are equivalent to 1 molecule of H_3PO_2 . This process is applicable to ammonium, potassium, calcium and manganese hypophosphites. For iron hypophosphite it must be modified as follows:—To about 0.15 g., accurately weighed, in a 200 ml. graduated flask, add 100 ml. of N/10 bromine and 20 ml. of dilute sulphuric acid; stopper the flask and shake well. Allow to stand, shaking occasionally until solution is complete. Add 30 ml. of 10% w/v sodium hydroxide solution, cool, and make up to volume. Filter, and to 100 ml. of filtrate add 10 ml. of 20% w/v potassium iodide solution and excess of dilute sulphuric acid, and titrate with N/10 sodium thiosulphate.—G. L. Jenkins and C. F. Bruening, *J. Amer. pharm. Ass.*, 1936, 19.

Tentative methods for the determination of hypophosphites in syrups are described in *Methods of Analysis (A.O.A.C., 1940, 617)*.

Calcii Hypophosphis (B.P.C. Supp. V). $\text{Ca}(\text{H}_2\text{PO}_2)_2 = 170.2$. Assayed by digestion in the dark for 12 hours with sulphuric acid and standard iodine solution and back titration with thiosulphate, a blank determination being made, it contains 98% of the pure substance; phosphate insoluble in water, not more than 0.5%. The N.F. VII substance is assayed similarly to the ammonium salt; 1 ml. of N/10 bromine = 0.002127 g. of $\text{Ca}(\text{H}_2\text{PO}_2)_2$; loss over sulphuric acid, not more than 3% and then contains 98% of the pure substance.

Ferri Hypophosphis (B.P.C. Supp. IV). $\text{Fe}(\text{H}_2\text{PO}_2)_3 = 250.9$. Contains from 97% to the equivalent of 101% of $\text{Fe}(\text{H}_2\text{PO}_2)_3$, after drying at 100°, when it loses not more than 5%. Assayed by the B.P.C. '34 method by digestion with potassium iodide and N/10 iodine in presence of hydrochloric acid in the dark for 4 hours, followed by back titration with N/10 sodium thiosulphate, by which the iodine liberated by the ferric radicle less that used in oxidising the hypophosphorous acid is titrated, a blank titration being made. Ferri Hypophosphis, N.F. VII, is estimated for Fe content only by evaporation with nitro-hydrochloric acid, interaction with potassium iodide in acid solution and titration of the liberated iodine, an Fe content on the dried substance of not less than 21.8% being indicated, equivalent to 98% of $\text{Fe}(\text{H}_2\text{PO}_2)_3$; loss over sulphuric acid, not more than 3%.

Mangani Hypophosphis (*B.P.C.*). $\text{Mn}(\text{H}_2\text{PO}_2)_2 \cdot \text{H}_2\text{O} = 203.0$. Estimated by hypophosphite content a purity of not less than 97% is required. As indicated by treatment with N/10 bromine solution and dilute sulphuric acid during 3 hours, and titration, with sodium thiosulphate, of the iodine liberated from potassium iodide, the *N.F. VII* salt dried over sulphuric acid for 2 hours is of the same purity.

Potassii Hypophosphis (*B.P.C.*). $\text{KH}_2\text{PO}_2 = 104.1$. Assayed by the *B.P.C.* method for Calcii Hypophosphis it contains 98% of KH_2PO_2 , after drying over sulphuric acid. Loses not more than 2% on drying over sulphuric acid. Insoluble phosphate limit, 0.5%. Potassii Hypophosphis, *N.F. VII*, assayed by the bromine absorption method, contains 98% of the pure substance after losing not more than 5% over sulphuric acid. 1 ml. of N/10 bromine = 0.002604 g. of KH_2PO_2 .

Sodii Hypophosphis (*B.P.C.*). $\text{NaH}_2\text{PO}_2 = 88.03$. By the assay process for Calcii Hypophosphis it contains 97% of the pure substance, calculated to the dry substance, a loss of 2% being allowed at 110°. Sodii Hypophosphis, *N.F. VII*, is the hydrated salt, $\text{NaH}_2\text{PO}_2 \cdot \text{H}_2\text{O}$, of which it should contain 98%, after drying for 2 hours over sulphuric acid; this loss should be not more than 3%; assayed by the bromine absorption method used for the ammonium salt of the *N.F. VII*. Hypophosphite de Sodium, *Fr. Cx.* 1937, by weight of the precipitate produced with mercuric chloride contains not less than 95% of the anhydrous substance.

ACIDUM LACTICUM

Acidum Lacticum (*B.P.*). Contains the equivalent of not less than 87.5% *w/w* of $\text{C}_3\text{H}_5\text{O}_3$; it is assayed to include both lactic acid and lactide, by boiling for five minutes with excess of normal sodium hydroxide and back titration with sulphuric acid to phenolphthalein, a blank titration being made. Sp. gr. about 1.21. A test for limit of various reducing sugars is included as shown by the formation of not more than a slight red precipitate on boiling the neutralised acid with Fehling's solution. The acid of the *B.P.* '14 contained 75% of hydrogen lactate with 10% of lactide. Lactic acid, *U.S.P. XII*, contains the equivalent of 85 to 90%; also assayed with excess of sodium hydroxide but with boiling for 20 minutes. Should give no reactions for sarcolactic acid with copper sulphate solution, or for citric, oxalic, phosphoric or tartaric acids with calcium hydroxide solution. The *P.G. VI* requires (with sp. gr. 1.206 to 1.216) total acid 90%, of which about 72% is free acid, reckoned as lactic acid. Assay process: 5 g. of lactic acid is diluted with water to 100 ml. 40 ml. of this mixture is neutralised with N/1 KOH in presence of phenolphthalein, using approx. 16 ml. of test solution (=72% of lactic acid). Further 5 ml. of N/1 KOH is added and the mixture warmed

5 minutes on the water-bath until the pink colour of phenolphthalein has disappeared. Then 2 ml. of N/1 HCl is added with further 2 minutes warming. The excess acid is back titrated. The total N/1 KOH used less the total N/1 HCl must be approx. 20 ml., i.e., approx. 90% total acid. *Acide Lactique Officiel, Fr. Cx.* 1937, assayed similarly, contains not less than 60% of lactic acid and not more than 30% of lactic anhydride. *Acidum lacticum, P. Helv. V.*, contains 88 to 92% w/w of total lactic acid. *Acidum Lacticum Dilutum, B.P.C.*, contains about 15% by volume of lactic acid and has a sp. gr. of about 1.04.

The absence from the *B.P.* of any limit for lactide is a disadvantage if the acid is used for the preparation of *Calcii Lactas Recens.*—*Retail Chem.*, ii/1932, 271.

Detection of Lactic Acid. A bright red coloration is obtained when 0.2 ml. of solution, containing less than 0.2% of lactic acid, is heated for two minutes at 100° with 2 ml. of conc. H_2SO_4 , cooled and treated with two drops of 5% alcoholic guaiacol solution.

This reaction is not given by formic, acetic, malic, benzoic or salicylic acids. Citric acid gives a yellow colour, tartaric acid a slight red colour, and tannin a blackish-violet.—*J. chem. Soc. Abstr.*, ii/1921, 356.

Calcii et Sodii Lactas (B.P.C. Supp. V).

$C_{12}H_{20}O_{12}CaNa_2 \cdot 4H_2O = 514.3$. Contains 7.5 to 8.5% of Ca and 8.5 to 10% of Na. A free acid limit equivalent to approximately 0.9% of lactic acid is included. Calcium is determined gravimetrically, by precipitation as oxalate and titration with sulphuric acid of the ignited residue; titration of the total alkalinity of the ash, less the titration for calcium, is calculated to Na.

Assay. Moisture.—This is best determined by drying for 2 hours below 100° and subsequently to constant weight at 130°. **Calcium.**—Instead of titrating the ignited oxalate with N/10 sulphuric acid, it is better to dissolve in N/2 hydrochloric acid and back titrate with N/2 sodium hydroxide. **Sodium.**—Dissolve the substance (containing 5 to 10 mg. of sodium) in 5 to 10 ml. of water and for every 3 mg. of sodium anticipated add 3 ml. of Kahane's reagent (magnesium acetate 100 g., uranyl acetate 32 g., glacial acetic acid 20 ml., alcohol (90%) 500 ml., water to 1 litre, heat on a steam-bath until dissolved, cool, filter at 20° and store in an amber-coloured bottle). Cool in ice-cold water for 30 minutes, stirring occasionally. Collect the precipitate in a sintered glass crucible, wash with 5 to 10 ml. of reagent, followed by 10 ml. of alcohol (95%). Dry at 105° to 110°. 1 g. of residue = 0.0153 g. of Na. **Lactic Acid.**—Dissolve 0.35 g. in 20 ml. of water, and add 30 ml. of 10% sulphuric acid and 25 ml. of N/2 potassium dichromate. Reflux for 15 minutes, cool, dilute, add 10 ml. of 10% potassium iodide solution and, after five minutes, titrate with N/10 thiosulphate, a blank being carried out simultaneously.—S. G. Liversedge, *Quart. J. Pharm.*, 1937, 364.

Calcii Lactas (B.P.). $C_6H_{10}O_6Ca \cdot 5H_2O = 308.2$. As indicated by weight of the sulphated residue, it contains from 97% to the equivalent of 103% of the pure substance. The *B.P.*'14 required a purity of only 93% and a test for limit of various sugars was not included. *Calcii Lactas, U.S.P. XII*, dried at 120°, loses 25 to 30% of water and then contains not less than 98% of the anhydrous salt; determined by precipitation with ammonium oxalate, decomposition of the precipitate with sulphuric acid and titration with N/10 potassium permanganate. *Lactate de Calcium, Fr. Cx.* 1937, yields not less than 70% of the anhydrous salt which contains not less than 98% of the pure substance, corresponding to 17.82% CaO. *Calcium lacticum, P. Helv. V.*, yields 43 to

46% of CaSO_4 , corresponding to 68.9 to 73.7% of the anhydrous lactate and loses 27 to 29.5% at 120° to 125° . Calcium lacticum, *P.G. VI*, contains 70.5 to 73% of anhydrous calcium lactate.

An examination of a large number of commercial and specially prepared samples showed that there are two kinds of calcium lactate. One is soluble in 20 parts of water at 23° and the other is soluble in 16 parts of water. Since different methods of manufacture give products of different solubility it is useless to set a single standard for solubility.—N. Glass, *Quart. J. Pharm.*, 1933, 522.

The solubility does not decrease on keeping nor is there any appreciable loss of water of crystallisation. The solubility varies with the method of preparation but does not appear to be due to any variation in constitution.—G. H. Macmorran, *Pharm. J.*, i/1933, 245.

Tabellæ Calcii Lactatis (*N.F. VII*). Contain 92.5 to 107.5% of the labelled amount of calcium lactate, including all tolerances. Assayed by ignition to carbonate, dissolving the residue in dilute hydrochloric acid, filtering and precipitating the calcium in an aliquot of the filtrate with ammonia and ammonium oxalate solution, filtering and washing the precipitate, finally transferring the filter to a flask, adding water and dilute sulphuric acid and titrating with N/10 potassium permanganate.

Ethyl Lactate, $\text{CH}_3\text{CHOH}\cdot\text{COOC}_2\text{H}_5$, a colourless liquid used as a solvent. *B.S.S. No.* 663—1936 includes requirements regarding specific gravity (1.032 to 1.040 at 15°), distillation range (not less than 96% between 135° and 160°), residue, acidity, ester content and miscibility in all proportions with petroleum ether and water.

Ferri Lactas (*B.P.C.*). $\text{C}_6\text{H}_{10}\text{O}_6\text{Fe}\cdot 3\text{H}_2\text{O} = 288.0$. Residue on ignition, 26.5 to 28.5%, being equivalent approximately to a purity of 96%. Tartaric, citric and malic acids are tested for by addition of lead acetate solution. By titration with sodium thio-sulphate of the iodine liberated on the addition of potassium iodide and hydrochloric acid, a ferric iron limit of about 0.8% is specified. The *Fr. Cx.* 1937 substance yields on ignition 27% of Fe_2O_3 .

Sodii Lactas (*B.P. Add. IV*). $\text{C}_3\text{H}_5\text{O}_3\text{Na} = 112.04$. Contains 68 to 72% *w/w* of the pure salt, by ignition and titration of the residue with excess N/2 sulphuric acid and N/2 sodium hydroxide, using methyl orange indicator. Limits of alkalinity and of various sugars are included.

ACIDUM MANDELICUM

Acidum Mandelicum (*B.P. Add. IV and VI*).

$\text{C}_6\text{H}_5\text{CHOH}\cdot\text{COOH} = 152.1$. Contains not less than 99.5% of $\text{C}_6\text{H}_5\text{O}_3$, by titration with N/10 sodium hydroxide to phenolphthalein. *M.p.*, 119° to 121° . Loss at 100° , not more than 0.5%. Ash, not more than 0.1%. A test for limit of chlorinated compounds is included. The *U.S.P. XII* requires Acidum Mandelicum, after drying for 24 hours over sulphuric acid, to contain not less than 99.0% of the pure substance.

Tentative methods for the determination of mandelic acid and its salts in tablets and liquid preparations are described in *Methods of Analysis* (*A.O.A.C.*, 1940, 610). The mandelic acid, extracted with chloroform-ether (2 + 1) from an acidified solution of the sample, is dissolved in water free from carbon dioxide and titrated with standard sodium hydroxide, using phenolphthalein as indicator.

Estimation in Preparations. A convenient method is presented for determining mandelic acid in calcium mandelate, monoethanolamine mandelate

and elixir of mandelic acid, which involves an ether extraction in acid solution and a direct titration by means of N/10 barium hydroxide solution.—A. N. Stevens and E. J. Hughes, *J. Amer. pharm. Ass.*, 1939, 222.

Calcii Mandelas (U.S.P. XII). $\text{Ca}(\text{C}_8\text{H}_7\text{O}_3)_2 = 342.3$. Dried at 110° , loses not more than 1% and then contains 98.5% of $\text{Ca}(\text{C}_8\text{H}_7\text{O}_3)_2$. Tests for completeness of solution in boiling water, free acid, chloride, sulphate and heavy metals are included. Magnesium and alkali salts are determined by dissolving the sample in dilute hydrochloric acid, rendering the solution alkaline with ammonia, precipitating the calcium as oxalate, filtering and evaporating an aliquot of the filtrate with 0.5 ml. of sulphuric acid to dryness. 0.5 g. should yield not more than 10 mg. of residue. Assayed by precipitation with ammonium oxalate, washing the residue, decomposition of the calcium oxalate with dilute sulphuric acid and titration with N/10 potassium permanganate.

ACIDUM NITRICUM

Acidum Nitricum (B.P.). Contains 69 to 71% by weight of HNO_3 . Sp. gr., about 1.42. Acidum Nitricum Dilutum, B.P.C. contains 9.5 to 10.5% w/w of HNO_3 , with sp. gr. 1.054 to 1.060 and is of the same strength as the dilute acid of the B.P. '14. The acid of the U.S.P. XII contains 67 to 71% of HNO_3 . The *Fr. Cx.* 1937 acid contains not less than 63.05% of HNO_3 . Acidum nitricum, P.G. VI, contains 24.8 to 25.2% of HNO_3 . Acidum nitricum crudum 61 to 65% and Acidum nitricum fumans not less than 86%. Acidum nitricum concentratum, P. *Helv.* V, contains 64 to 66% w/w of HNO_3 .

British Standard Density-Composition Tables for Aqueous Solutions of Nitric Acid (B.S.S. No. 975—1941) give the concentration in g. of HNO_3 per 100 g. and in g. of HNO_3 per 1000 ml. corresponding to densities of 1 to 1.531 for each 2° over the range 10° to 40° . The tables are designed for use in conjunction with British Standard Density Hydrometers.

Nitrous Fumes in Industry

Nitrous fumes are usually reddish-brown in colour and may consist chiefly of a mixture of nitrogen peroxide (NO_2) with smaller quantities of nitric oxide (NO). They are formed by the action of concentrated nitric acid on metals or organic matter, such as wooden flooring, in the manufacture of nitric acid and sulphuric acid by the lead chamber process, and in the manufacture of explosives and dyes. In war-time they may cause trouble in confined spaces, such as gunpits, armoured cars and magazines, when combustion is incomplete. They are also liable to occur in mining operations, where explosives are employed. The fumes are exceedingly dangerous on account of the delayed action and workmen may be unaware of any effects but collapse after returning home, oedema of the lungs developing and death occurring in about 24 hours. Exposure to from 2 to 8 parts per 10,000 for a short time may be fatal, even 1 to 1.5 parts per 10,000 for a short exposure being dangerous, whilst 1 part per 100,000 is the maximum concentration allowable for several hours' exposure.

Treatment. Prompt removal to fresh air is essential. The patient should be kept warm in a prone position, and given stimulants, such as tea, but not alcohol. Strict confinement to bed for not less than 2 days is advisable.

Detection and Determination. The official method does not determine actual nitrous fumes, but the quantity of nitrous acid or nitrogen trioxide present in the fumes and is dependent on the well-known Griess-Ilosvay reaction (see this volume, p. 853) for the determination of nitrites in water. For comparison a standard colour solution is prepared by acidifying an acetone solution of dimethylamino-azo-benzene with hydrochloric acid.—(*Toxic Gases in Industry*, No. 5, D.S.I.R.)

Potassii Nitras (B.P.). $\text{KNO}_3 = 101.1$. A purity of 99% is required. The assay process of the B.P. reduces the nitrate with nascent hydrogen obtained by addition of sulphuric acid and reduced iron, liberating the ammonia formed with sodium hydroxide, distilling into excess of standard acid and back titrating with sodium hydroxide; a blank titration is performed. Potassii Nitras, *U.S.P. XII*, contains 99% of KNO_3 after drying to constant weight at 110° ; assayed by evaporation with hydrochloric acid and titration of the chloride with silver nitrate and ammonium thiocyanate.

Uranii Nitras (B.P.C. Supp. IV). $\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O} = 502.2$. Determined by precipitation as hydroxide and ignition to oxide (U_3O_8), it contains not less than 98% of the pure hexahydrate. A 5% solution remains clear on the addition of an equal volume of ammonium carbonate solution (limit of alkaline earths) and does not show more than a faint darkening (due to lead, iron, manganese or zinc) on saturating with hydrogen sulphide. It should contain no more uranous compounds in 1 g. dissolved in 20 ml. water acidified with dilute sulphuric acid, than will decolorise 0.1 ml. of N/10 potassium permanganate.

Determination of Nitrates. Nitrates can be determined by using Nitron, *Syn.* 1 : 4-Diphenyl-3 : 5-endanilo-4 : 5-dihydro-1 : 2 : 4-triazole. $\text{C}_6\text{H}_5 \cdot \text{N} \cdot \text{N} : \text{C} \cdot \text{N}(\text{C}_6\text{H}_5) \cdot \text{CH} \cdot \text{N} \cdot \text{C}_6\text{H}_5$. The reagent is used as a 10% solution in N/1 acetic acid. To 100 ml. of aqueous solution containing 0.1 g. of the nitrate acidified with acetic acid and heated to boiling, is added 10 ml. of the reagent. The mixture is cooled at 0° for 2 hours and the precipitate then collected, washed with a saturated aqueous solution of nitron, dried at 110° and weighed. Each gramme of precipitate is equivalent to 0.1653 g. of NO_3 . Bromides, iodides, nitrites and chromates should be removed before the reagent is added.

Sodii Nitris (B.P.). $\text{NaNO}_2 = 69.005$. Estimated by titration of standard potassium permanganate, acidified with sulphuric acid, diluted, and warmed to 40° with a 0.5% solution of the salt. 95% purity is required. Sodii Nitris, *U.S.P. XII*, contains 97% after drying over sulphuric acid. A solution of the salt is added to excess acidified permanganate, warmed to 40° , stood for 5 minutes and then excess standard oxalic acid added, heated to 80° , and back titrated with permanganate. The *Fr. Cx.* 1937 requires the same purity.

Tabellæ Sodii Nitritis (*U.S.P. XII*). Contain 93 to 107% of the labelled amount of NaNO_2 , including all tolerances. Assayed by dissolving a weighed quantity in water, filtering, making up the filtrate to volume, adding saturated potassium chlorate solution and N/10 silver nitrate followed by nitric acid to an aliquot of the solution, filtering and titrating the excess of N/10 silver nitrate in an aliquot of the filtrate with N/10 ammonium thiocyanate. If more than 0.1% of Cl is present, it is determined by treating the same volume of tablet solution with N/10 silver nitrate and nitric acid, heating until no more nitrous fumes are evolved, filtering and titrating an aliquot of the filtrate with N/10 ammonium thiocyanate. The volume of N/10 silver nitrate required by the Cl present is then deducted from the volume consumed in the assay.

Liquor Æthylis Nitritis Concentratus (*B.P. Add. V*). Contains, when freshly prepared, 17.0 to 20% *w/v* of $\text{C}_2\text{H}_5\text{O}_2\text{N}$, or after storage or when the container has been opened occasionally, not less than 10% of $\text{C}_2\text{H}_5\text{O}_2\text{N}$; determined by the process described under *Spiritus Ætheris Nitrosi*.

Spiritus Ætheris Nitrosi (*B.P.*). Contains from 1.25 to 2.5% *w/v* of ethyl nitrite, approximately the same as the *B.P.* '14 preparation which was required to contain 1.52 to 2.66% *w/w*. Sp. gr., 0.838 to 0.842. There is also a test for limit of acid. Assayed by the *B.P.* process in which the ethyl nitrite is decomposed by shaking in a brine-charged nitrometer with potassium iodide solution and dilute sulphuric acid, the liberated nitric oxide being measured. Each ml. of moist nitric oxide is equivalent to 0.0032 g. of $\text{C}_2\text{H}_5\text{O}_2\text{N}$. *Spiritus Æthylis Nitritis, N.F. VII*, contains 3.5 to 4.5% *w/w* of $\text{C}_2\text{H}_5\text{ONO}$; determined by passing carbon dioxide through a cooled solution of potassium iodide, deaerated water, and dilute hydrochloric acid, decolorising if necessary with N/10 sodium thiosulphate, adding the spirit just above the surface of the liquid and immediately titrating with N/10 sodium thiosulphate; both the pipette and tip of the burette are introduced into the flask through an outlet tube. *Spiritus Ætheris nitrosi, P. Helv. V*, is a solution in absolute alcohol containing from 2 to 2.5% *w/v* of ethyl nitrite. It is assayed as follows:—Shake vigorously for 5 minutes in a closed flask 20 ml. of N/10 silver nitrate, 10 ml. of the spirit, 20 ml. of saturated solution of potassium chlorate and 5 ml. of dilute nitric acid, and then dilute to 100 ml. with water. Filter and titrate 50 ml. of the filtrate with N/10 ammonium thiocyanate using iron alum as indicator; each ml. of N/10 AgNO_3 used up is equivalent to 0.022515 g. of $\text{C}_2\text{H}_5\text{O}_2\text{N}$.

This preparation decomposes even when kept under the best conditions. The first change is probably the formation of aldehyde and nitrous acid, and then the aldehyde is oxidised into acetic acid. In the course of time the nitrous constituent of the spirit entirely disappears, but aldehyde, one of the most readily oxidisable bodies, remains. The spirit should be kept in cool cupboards and in well-filled bottles, preferably upside down.

With regard to the volatilisation of ethyl nitrite, Cowley has shown that every trace of ethyl nitrite disappears from a solution within a few days in ordinary vessels. As to decomposition in an aqueous solution, a mixture containing spirit of nitre loses the whole of it in three days. Solutions in absolute alcohol change less rapidly than those in 90% alcohol on account of the water present. A mixture of 90% alcohol and glycerin in equal volumes is a good solvent for all preparations of ethyl nitrite.

ACIDUM OLEICUM

Acidum Oleicum (B.P.). Consists chiefly of $C_{17}H_{33}COOH$. Sp. gr., about 0.898. Acid value, 195 to 200. Iodine value, 85 to 90. It should not become cloudy on cooling until a temperature of 10° has been reached; a higher point indicates the presence of stearic acid; it congeals at about 4° . Should comply with limits for mineral acids and for neutral fats and mineral oils. Ash not more than 0.1% w/w. The *U.S.P. XII* substance has a congealing temperature not above 10° ; acid value, 188 to 203; iodine value, 85 to 95. Acidum oleicum, *P. Helv. V*, has an acid value of 195 to 205 and an iodine value, 78 to 90.

Acidum Ricinoleicum (B.P. Add. VI). Sp. gr., 0.945 to 0.948. Acid value, not less than 175. Iodine value, 85 to 91. n_D at 40° , 1.462 to 1.468.

Acidum Stearicum (B.P.C.). Should not melt below 54° . Acid value, 200 to 210. Complies with a limit test for neutral fat or paraffin. Acidum Stearicum, *U.S.P. XII*, has a congealing point not below 54° . Iodine value, not more than 4.

Alcohol Cetylicum (B.P.C. Supp. III). M.p., 48° to 52° . Ash, not more than 0.1%. Iodine value, not more than 20. Tests for limit of paraffin and of fatty acids are included.

ACIDUM PHOSPHORICUM

Acidum Phosphoricum (B.P.). Contains 88 to 90% w/w of H_3PO_4 with a sp. gr. of about 1.75. The corresponding acid of the 1914 Pharmacopœia contained only 66.3% with sp. gr. 1.5. No brown colour, indicative of phosphorous and hypophosphorous acids, is produced on warming with silver nitrate. Acidum Phosphoricum Dilutum, *B.P.*, contains 9.5 to 10.5% w/w of H_3PO_4 . Assayed in saturated salt solution by titration with N/1 sodium hydroxide, using phenolphthalein as indicator; each millilitre of normal solution is equivalent to 0.04902 g. of H_3PO_4 . The corresponding acids of the *U.S.P. XII* contain 85 to 88% w/w and 9.5 to 10.5% w/v of H_3PO_4 respectively. Tests for phosphate, in which no turbidity should be produced with ether (6 parts) and alcohol (2 parts), and for nitrate by treatment with sulphuric acid and indigo solution, are included. Acide Phosphorique Officinal, *Fr. Cx. 1937*, determined by precipitation with magnesia mixture and ignition to pyrophosphate, contains not less than 49.7% of H_3PO_4 . The dilute acid contains 10% H_3PO_4 . Acidum phosphoricum, *P.G. VI*, contains 24.8 to 25.2% of H_3PO_4 .

The best method for the complete titration of P_2O_5 , NaH_2PO_4 and Na_2HPO_4 is the use of phenolphthalein at a temperature of 55° to 70° after $CaCl_2$ has been added to the phosphate solution. The proportion of phosphate to $CaCl_2$ should be 1 in 2 to 1 in 5.—*per Yearb. Pharm.*, 1926, 305.

Metaphosphoric Acid, $HPO_3=80.0$, is equivalent to *glacial phosphoric acid*, and is employed as an albumin test (*vide Urine*, p. 641).

Ammonii Phosphas (B.P.C.). A mixture of the di-ammonium and di-hydrogen salts, containing not less than 20% of NH_3 . The B.P.C. directs 1 g. to be dissolved in 200 ml. of water, 25 ml. of 25% sodium hydroxide solution added, the liberated ammonia distilled into 50 ml. of N/2 sulphuric acid and the excess acid titrated with N/2 sodium hydroxide to methyl red.

Calcii Phosphas (B.P.). Assayed by addition of ammonium acetate and ammonium oxalate to a solution slightly acidified with hydrochloric acid, heating and allowing to stand for several hours, filtration and ignition with sulphuric acid of the washed precipitate. Contains calcium equivalent to 85% of $\text{Ca}_3(\text{PO}_4)_2$. Calcii Phosphas Tribasicus, U.S.P. XII, loses not more than 8% on ignition, and then contains not less than 90% of $\text{Ca}_3(\text{PO}_4)_2$. Determined by precipitation with ammonium molybdate solution, decomposition of the washed precipitate with N/1 sodium hydroxide and back titration with N/2 sulphuric acid, using phenolphthalein indicator. Limit of fluorine, not more than 0.005%; 2 g. of the substance, 5 ml. of perchloric acid and 15 ml. of distilled water is distilled at 135° to 145° , by gradual additions of water, until 70 ml. has been collected. An aliquot is adjusted to the same reaction to sodium alizarinsulphonate as distilled water by addition of N/20 sodium hydroxide. 1 ml. of N/10 hydrochloric acid is added to the solution and to the water control, and 0.025% thorium nitrate is added gradually to the test solution until the liquid is faintly pink and the same quantity added to the water control. Sodium fluoride solution (0.00222%) is then added to the control until after adjusting to the same volume, the colours match. By weight of magnesium pyrophosphate the *Fr. Cx.* 1937 requires Phosphate Di-acide de Calcium to contain 97% of the monohydrate, Phosphate Mono-acide de Calcium to contain 97% of the dihydrate, and Phosphate Neutre de Calcium, determined on the substance dried at 100° , to contain 92% of the anhydrous substance; loss of the latter at 100° , not more than 3% and on incineration not more than a further 5%. Calcium phosphoricum, *P.G. VI*, leaves 25 to 26.2% of residue on ignition. Calcium phosphoricum bibasicum, *P. Helv. V*, is determined by dissolving 1 g. in 25 ml. of N/1 hydrochloric acid, diluting with 150 ml. of water and titrating to methyl orange with N/1 sodium hydroxide; 1 ml. is equivalent to 0.1361 g. of CaHPO_4 and the salt should contain from 78.8 to 80.2% of anhydrous CaHPO_4 . Mono- and tribasic salts are excluded by titration to phenolphthalein after the previously neutralised solution has been treated with neutral calcium chloride solution. The same salt for veterinary use must contain from 35 to 38% of P_2O_5 . Calcium phosphoricum monobasicum, *P. Helv. V*, contains not more than 5% of free phosphoric acid and not less than 92% of $\text{Ca}(\text{H}_2\text{PO}_4)_2 + \text{H}_2\text{O}$. Phosphoric acid determined by titration to methyl orange with N/1 sodium hydroxide and $\text{Ca}(\text{H}_2\text{PO}_4)_2$ by continuing the titration to phenolphthalein with addition of calcium chloride, calculating by subtracting twice the methyl orange reading from the phenolphthalein reading. Calcium

phosphoricum tribasicum, *P. Helv. V*, is assayed by dissolving about 1 g., accurately weighed, in 25 ml. of N/1 hydrochloric acid, diluting with 200 ml. of water and, after adding 3 or 4 drops of methyl orange, titrating with N/1 sodium hydroxide until the red colour disappears, rotating constantly to redissolve the precipitate formed. Each ml. of N/1 HCl is equivalent to 0.07756 g. of $\text{Ca}_3(\text{PO}_4)_2$ and the salt should contain not less than 95%.

Determination of Phosphorus in Syrups. An amount of material corresponding to from 15 to 20 mg. of P_2O_5 is dissolved in 70 ml. of water, 5 ml. of nitric acid is added and 10 g. of ammonium nitrate, and the temperature raised to 65°. To the stirred solution is then added, in a thin stream, 35 ml. of nitric acid solution of ammonium molybdate. The mixture is stirred for a further 30 seconds, allowed to stand at a temperature of 65° to 70° for 15 minutes, removed from the water-bath and allowed to cool for a further 15 minutes, the supernatant liquid being then filtered off through an asbestos or paper pulp filter in a Gooch crucible under slight suction. The precipitate is washed, as far as possible by decantation, with two 20 ml. portions of 5% nitric acid, then with five 20 ml. portions of 5% ammonium nitrate solution, and finally with small quantities of water. The final washings should not redden litmus paper. The precipitate is transferred to the original beaker, the crucible being washed out with about 50 ml. of water, 50 ml. of N/5 sodium hydroxide (free from carbonate) is added, the yellow precipitate allowed to dissolve completely, and the excess of alkali titrated with N/5 hydrochloric acid, using thymol blue or phenol violet as indicator and titrating to the yellowish-green tint.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1934, 347.

Magnesii Phosphas (B.P.C. Supp. IV). Consists of $\text{Mg}_3(\text{PO}_4)_2$ with about 30% of combined water. The residue on ignition is not less than 68%. **Magnesii Phosphas Tribasicus, U.S.P. XII**, loses on ignition, 20 to 27% of its weight and then contains not less than 98% of $\text{Mg}_3(\text{PO}_4)_2$. Assayed by the method described for **Calcii Phosphas Tribasicus**. Limits for carbonate, residue insoluble in hydrochloric acid (0.2%), barium, heavy metals, arsenic, soluble salts (1.5%), sulphate, chloride, nitrate, calcium and of dibasic salt and magnesium oxide are included.

Tabellæ Magnesii Phosphatis Tribasici, (U.S.P. XII). Contain 94 to 108% of the labelled amount of $\text{Mg}_3(\text{PO}_4)_2 \cdot 5\text{H}_2\text{O}$, including all tolerances. Limit tests for calcium and soluble salts are included. Assayed by igniting a weighed quantity of powdered tablets, dissolving the residue in nitric acid and water, filtering and thoroughly washing the filter with hot water. After the filtrate has been made slightly alkaline with ammonia solution, the precipitate formed is dissolved by addition of nitric acid and the solution warmed to 50° and solution of ammonium molybdate added. The mixture is kept at 50° for 30 minutes and the precipitate then washed with cold water until free of acid. The precipitate is dissolved in a known excess of N/1 sodium hydroxide and the excess alkali titrated with N/2 sulphuric acid, using phenolphthalein indicator.

Potassii Phosphas (B.P.C.). $\text{K}_2\text{HPO}_4 = 174.2$. Loses not more than 5% at 100° and then contains 98% of the pure substance. Assayed by titration with N/2 sulphuric acid to the green colour of bromocresol green indicative of pH 4.5, which converts the dipotassium compound into the di-hydrogen compound.

Potassii Phosphas Acidus (B.P.C.). $\text{KH}_2\text{PO}_4 = 136.1$. Contains 97% of KH_2PO_4 . Titrated with standard sodium hydroxide in the presence of sodium chloride using phenolphthalein as indicator. A limit of dipotassium phosphate by neutralisation with N/10 sulphuric acid to the pH 4.5 green colour

of bromocresol green, equivalent to about 1.7% of K_2HPO_4 , is included.

Sodii Phosphas (*B.P. Add. I*). $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O} = 358.2$. Assayed by titration to pH 4.5 with N/2 sulphuric acid using bromocresol green as indicator, which replaces the *B.P.* '14 titration to NaH_2PO_4 with methyl orange indicator. Contains from 99% to the equivalent of 105% of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$. A test for absence of fluorides, by treatment of a solution acidified with acetic acid, with calcium chloride solution is included; no turbidity should be produced on standing for 1 hour. Sodii Phosphas, *U.S.P. XII*, loses 43 to 50% at 110° , and then contains not less than 98% of Na_2HPO_4 ; assayed by precipitation with magnesia mixture, finally weighing the ignited residue of pyrophosphate.

Sodium phosphate may contain fluoride as impurity, which may cause serious disturbance in biochemical work.—A. Harden, *Nature, Lond.*, ii/1934, 101.

The addition of 10 ml. of a 33% solution of sodium hexametaphosphate (Calgon) to the Fehling's solution immediately before the addition of the invert sugar will eliminate interference due to the presence of calcium. When an excess of sodium hexametaphosphate is added to a solution of a calcium salt the calcium becomes inert and cannot be detected by any of the normal reagents.—J. G. W. Gaskin, *Analyst*, 1935, 318.

Sodii Phosphas Acidus (*B.P.*). $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O} = 156.1$. Contains not less than 98% of the pure salt. It is assayed by titration with N/2 sodium hydroxide after the addition of 25% of sodium chloride. A titration of not more than 1 ml. of N/10 sulphuric acid for 1 g. of salt, to bromocresol green, represents a limit of the di-sodium salt equivalent to about 1.4% of Na_2HPO_4 . The *U.S.P. XII* requires Sodii Biphosphas to lose 10 to 15% of water when dried for 1 hour at 60° and then at 100° ; it then contains 98% of the anhydrous acid phosphate; the acidity or alkalinity (disodium phosphate) to methyl orange of 2 g. is between 0.3 ml. N/1 sodium hydroxide and 0.3 ml. N/1 sulphuric acid. Phosphate Monoacide de Sodium, *Fr. Cx.* 1937, contains not less than 99% of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$. The anhydrous salt contains not less than 98%.

Sodii Phosphas Exsiccatus (*B.P.C.*). Loses not more than 2% at 100° and then contains 99% of Na_2HPO_4 , determined by the *B.P.* method for Sodii Phosphas. Sodii Phosphas Exsiccatus, *U.S.P. XII*, contains 98% of the anhydrous compound after drying to constant weight at 110° ; loss at 110° , not more than 5%; assayed by precipitation as magnesium ammonium compound and ignition to pyrophosphate.

Sodium Acid Pyrophosphate, as used in baking powder, is the anhydrous compound, $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$. The aqueous solution is neutral to methyl orange and acid to phenolphthalein.

Estimation of Phosphates. The following modified procedure for the colorimetric determination of phosphates is recommended:—*Reagents.* Ammonium molybdate solution, 5 g. of ammonium molybdate in 100 ml. of N sulphuric acid.

Hydroquinone solution, 0.5 g. of hydroquinone dissolved in 100 ml. of distilled water made slightly acid with one drop of concentrated sulphuric acid.

Sodium succinate solution, 20 g. (anhydrous basis) of sodium succinate in 100 ml. of distilled water. *Sample.* All phosphorus should be in the ortho

form of the acid in clear colourless solution at about pH 5.0. *Procedure.* To an aliquot of the sample equivalent to not more than 0.3 mg. phosphorus and contained in a volume of not less than 10 ml., add the following in order, mixing well after each addition: (1) 2 ml. ammonium molybdate solution, (2) 2 ml. hydroquinone solution, (3) 2.5 ml. sodium succinate solution. Adjust the volume to 25 ml. with distilled water and measure the colour at 460 m μ within four hours.—L. S. Stoloff, *Industr. Engng Chem. (anal. Edn.)*, 1942, 637.

ACIDUM SALICYLICUM

Acidum Salicylicum (B.P.). $C_6H_4OH \cdot COOH = 138.0$. M.p., 158° to 159°. When titrated in alcoholic solution with N/2 sodium hydroxide using phenol red as indicator a purity of 99.5% is indicated. Ash not more than 0.05%. No assay was included in the 1914 Pharmacopœia. The *U.S.P. XII* requires the same purity after drying the acid for 5 hours over sulphuric acid; titration of a solution in alcohol is made with N/10 sodium hydroxide using phenolphthalein as indicator. Acidum salicylicum, *P. Helv. V*, is required to contain at least 99.6% of the pure acid and to melt between 155° and 157°.

Vanadate Test for Salicylic Acid. Mix equal parts by volume of 40% formaldehyde and conc. sulphuric acid and cool the mixture thoroughly. Moisten the substance to be tested in a dish with the mixture, add a little ammonium vanadate and stir well. If salicylic acid is present a prussian blue colour appears immediately, changing rapidly to greenish blue and finally green. For about 1 mg. of salicylic acid use 2 drops of the liquid and 2 to 3 mg. of ammonium vanadate. The only other substance giving the colour is salicylic aldehyde.—*Pharm. J.*, i/1915, 521.

The second report of the Commission Internationale des Spécialités includes an agreed method for the determination of salicylic acid in which the acid is converted to tribromophenol by the addition of excess of bromide-bromate solution and acidifying, the excess of bromine being determined iodometrically.—*Bull. Fed. int. Pharm.*, 1938, 76.

Assay of Ointment. The following assay for salicylic acid in the *B.P.* 1932 ointment is recommended by the Sub-Committee on the Assay of Galenicals of the Committee on Pharmaceutical Chemistry:—Boil about 5 g., accurately weighed, with 20 ml. of water and 20 ml. of N/1 sodium hydroxide under a reflux condenser for fifteen minutes. Filter through a wet filter paper, wash the residue and filter with hot water; cool, and dilute the mixed filtrate and washings to 100 ml. Transfer 50 ml. to a stoppered flask; add 50 ml. of N/10 bromine, 50 ml. of water and 5 ml. of hydrochloric acid, shake repeatedly during half an hour, add 15 ml. solution of potassium iodide and titrate with N/10 sodium thiosulphate. Each ml. of N/10 bromine is equivalent to 0.00230 g. of $C_6H_4O_2$. Limits of 1.9 to 2.1% of $C_6H_4O_2$ are suggested. (*British Pharmacopœia Commission Report*, No. 11, May 1939.)

The use of salicylic acid as a preservative is now illegal (see p. 837).

Detection. Concentrate liquid (distil off any alcohol) in presence of alkali and sodium chloride, acidify and shake out with chloroform, evaporate and add ferric chloride solution—violet colour. See also Scheme for Recognition of Organic Chemicals and under Acidum Benzoicum, p. 6.

Official quantitative and qualitative methods for the determination of salicylic acid in foods are described in *Methods of Analysis (A.O.A.C., 1940, 454)*.

Detection and Determination in Presence of Benzoic Acid. Nicholls's modification of the Jorissen test is advocated. To the solution to be tested, containing about 20 mg. of mixed acids in 25 ml., is added 1 ml. of 2% sodium nitrite solution and 1 ml. of 0.3% crystalline copper sulphate solution in 10% acetic acid. The mixture is heated in a boiling water-bath for 15 minutes, cooled and diluted to 50 ml. The red colour is matched against that given by a standard solution prepared by carrying out the test on 5 ml. of 0.1% salicylic

acid solution diluted to 40 ml., using 5 ml. each of the nitrite and copper sulphate solutions and diluting the final solution to 100 ml.

The benzoic acid may be determined after destroying the salicylic acid with alkaline potassium permanganate. The solution is warmed to 50° with 5 ml. of N/10 potassium hydroxide and N/10 permanganate added slowly until a pink colour persists. The mixture is then acidified with 1 in 3 dilute sulphuric acid and decolorised with acetic acid added drop by drop. The benzoic acid is extracted with ether from the solution saturated with ammonium sulphate, converted to the ammonium salt and determined by the method for foodstuffs (see p. 6). The method can be applied to the determination of sodium salicylate and sodium benzoate in compound glycerin of thymol by separating the mixed acids by acidification and extraction with ether following a preliminary extraction of the volatile oils from an unacidified 1 in 5 solution by means of ether.—F. W. Edwards, H. R. Nanji and M. K. Hassan, *Analyst*, 1937, 175.

A tentative method for the determination of salicylic acid in the presence of other phenols is described in *Methods of Analysis (A.O.A.C., 1940, 572)*.

Ammonii Salicylas (N.F. VII). $\text{NH}_4\text{C}_7\text{H}_5\text{O}_3 = 155.1$. After drying for 24 hours over sulphuric acid it contains not less than 98% of the pure substance; assayed by the method described for Sodium Salicylate, *B.P.*, using tenth-normal hydrochloric acid.

Magnesium Salicylas (B.P.C.). $\text{C}_{14}\text{H}_{10}\text{O}_6\text{Mg} \cdot 4\text{H}_2\text{O}$. Loses not more than 19% at 110° and then contains 99% of the anhydrous salt. Assayed by the *B.P.* process for Sodii Salicylas by titration with standard sulphuric acid to bromophenol blue.

Potassii Salicylas (B.P.C.). $\text{C}_7\text{H}_5\text{O}_3\text{K} = 176.1$. Dried at 110° it contains 99% of the pure substance. Moisture, determined at 110°, not more than 1%. Assayed by the *B.P.* ether-acid titration used for Sodii Salicylas.

Sodii Salicylas (B.P.). $\text{C}_6\text{H}_4\text{OH} \cdot \text{COONa} = 160.0$. A purity of 99.5% is required for the substance dried at 110°. Loss at 110° not more than 1%. The separated salicylic acid melts between 158° and 159°. It is assayed by titration with half normal sulphuric acid, removing the liberated acid with ether and using bromophenol blue as indicator. Sodii Salicylas, *U.S.P. XII*, after drying for 4 hours at 110°, contains 99.5% of $\text{NaC}_7\text{H}_5\text{O}_3$. Limit of moisture 0.5%; assayed similarly using N/2 hydrochloric acid. Salicylate de Sodium, *Fr. Cx.* 1937, assayed as the lithium salt, contains 99% of the sodium salt, corresponding to 85.4% of salicylic acid.

Tabellæ Sodii Salicylatis (U.S.P. XII). Contain 93 to 107% of the labelled amount of $\text{NaC}_7\text{H}_5\text{O}_3$, including all tolerances. Assayed by transferring a weighed quantity of powdered tablets to a separator with water, acidifying and extracting the liberated salicylic acid with ether, removing the ether, dissolving the residue in alcohol and water and titrating with N/10 sodium hydroxide, using phenolphthalein indicator.

Strontii Salicylas (N.F. VII). $(\text{C}_6\text{H}_4\text{OH} \cdot \text{COO})_2\text{Sr} \cdot 2\text{H}_2\text{O} = 397.7$. Loses not more than 3% over sulphuric acid for 2 hours, and then contains not less than 99% of the pure salt; assayed by titration with N/2 hydrochloric acid to methyl orange, removing the liberated salicylic acid with ether.

Methylis Salicylas (B.P. Add. I). $\text{C}_8\text{H}_8\text{O}_3 = 152.1$. Assayed for esters by saponification of the neutralised substance with N/2 alcoholic potash during one hour, dilution, and back titration with standard sulphuric acid to phenolphthalein, the equivalent of the titration for free acid being subsequently deducted. A blank titration on the alcoholic potash is performed; each millilitre of

N/2 alcoholic potash is equivalent to 0.07603 g. of $C_6H_5O_3$; a titration difference indicating not less than 98% should be obtained. Sp. gr., 1.186 to 1.191; refractive index at 20° , 1.536 to 1.583. Methylis Salicylas, *U.S.P. XII*, may be the synthetic or the natural substance and must be labelled accordingly. In assaying, the saponification is allowed to proceed for 2 hours; a purity of 98% is required.

Oleum Betulæ (B.P.C.). This naturally occurring oil should contain 98% *w/w* of esters calculated as methyl salicylate and determined by the *B.P.* ester process. Sp. gr., 1.182 to 1.192; optical rotation, $+0.5^\circ$ to -0.5° ; refractive index at 20° , 1.534 to 1.538.

Distinction from Methyl Salicylate. To 5 drops of the oil in a test tube add 5 drops of a 5% alcoholic solution of vanillin and 1 ml. of alcohol, shake well and add 2 ml. of concentrated sulphuric acid; mix thoroughly. Sweet birch oil gives a red coloration while methyl salicylate gives a yellow.—*Perfum. essent. Oil Rec.*, 1914, 60.

Salol (B.P.C.). $C_6H_4 \cdot OH \cdot COOC_6H_5$. The *B.P.C.* requires the substance to melt between 42° and 43.5° . Phenylis Salicylas, *U.S.P. XII*, melts between 41° and 43° .

Tabellæ Phenylis Salicylatis (N.F. VII). Contain 91 to 109% of the labelled amount of phenyl salicylate, including all tolerances. Comply with a test for absence of uncombined phenol and salicylic acid. Assayed by heating with sodium hydroxide solution for 45 minutes over a steam-bath, acidifying the solution and extracting the salicylic acid with ether, washing the ether extracts, evaporating the ether and finally titrating the residue, dissolved in neutral alcohol, with N/10 sodium hydroxide, using phenolphthalein indicator.

Tentative methods for the determination of mixtures of salol and phenacetin, and salol, phenacetin and acetylsalicylic acid are given in *Methods of Analysis (A.O.A.C., 1940)*.

Methylis Hydroxybenzoas (B.P.C. Supp. III). $C_6H_5O_3 = 152.1$. M.p., 122° to 130° . Ash not more than 0.1%. Methylis Parahydroxybenzoas, *N.F. VII*, m.p., 125° to 127° , when dried at 100° and assayed by hydrolysis with N sodium hydroxide and back titration with N sulphuric acid to pH 6.7, contains not less than 99% of $C_6H_5O_3$.

Propylis Hydroxybenzoas (B.P.C. Supp. III). $C_{10}H_{12}O_3 = 180.1$. M.p., 96° to 97° . Ash not more than 0.1%.

Methods are given for the detection and determination of *p*-hydroxybenzoic acid and its esters, cinnamic acid and anisic acid.—F. C. M. Jansen, *Chem. Weekbl.*, 1936, 33, 1.

Detection and Determination in Presence of Salicylic and Benzoic Acids.

Detection. The preservative is extracted from food products, etc., by means of an organic solvent and is hydrolysed with alcoholic potash to decompose any esters of *p*-hydroxybenzoic acid present. The acids are converted to the ammonium salts and the solution boiled until the vapour is neutral. The following tests are then applied to the solution:—(I) Millon's Reagent. (II) Iron Reagent B (see Determination of Benzoic Acid in Foodstuffs, see p. 6). (III) Jorissen's test (see p. 36). (IV) Copper sulphate—evaporate an aliquot part of the ammonium salt solution containing at least 2 mg. of the *p*-acid with 1 ml. of 2% copper sulphate solution on a water-bath to 1–2 ml. (V) Nicholls's benzoic acid test after oxidation of salicylic acid, if present, with alkaline permanganate (see p. 37). (VI) Mohler's test:—A portion of the ammonium salt solution is evaporated to dryness with sufficient N/10 potassium hydroxide

to form the potassium salt and the residue treated as described by Illing (*Analyst* 1927, 225). The following table gives the indications shown by these tests:—

| Test | Result | Inference | Remarks |
|---------------------------------|--|---|------------------------------------|
| I Millon .. | No red colour .. | Salicylic and <i>p</i> -acids absent | Omit tests II, III and IV. |
| | Red colour .. | Salicylic and/or <i>p</i> -acid present | Apply tests II, III and IV. |
| II Ferric chloride .. | Violet colour .. | (a) Salicylic acid present | Confirm by test III. |
| | | (b) <i>p</i> -Acid may also be present | In either case confirm by test IV. |
| | No violet colour | (a) <i>p</i> -Acid alone may be present | |
| | | (b) Salicylic acid absent | Omit test III. |
| III Jorissen .. | Pink colour .. | Confirms presence of salicylic acid. | |
| IV Copper salt | Characteristic crystalline precipitate | Confirms presence of <i>p</i> -acid. | |
| | No crystals within 12 hours | <i>p</i> -Acid absent. | |
| V Nicholls* .. | No violet colour | Benzoic acid absent. | Confirm by test VI. |
| | Violet colour .. | Benzoic acid present. | |
| VI Mohler as modified by Illing | Red colour .. | Confirms presence of benzoic acid. | |

Determination. In the absence of salicylic acid the *p*-acid is determined colorimetrically with Millon's reagent. 20 ml. of ammonium salt solution containing not more than 2 mg. of acid is heated with 2 ml. of the reagent. Different quantities of a standard solution of the *p*-acid are treated similarly and both test solution and the standard are heated in a boiling water-bath for 2 minutes, then diluted to 50 ml. in Nessler glasses and the colours compared. In the presence of salicylic acid, the latter is determined colorimetrically (*i.e.*, by test II or III above). A quantity of the ammonium salt solution containing, say, 0.5 mg. of salicylic acid is diluted to 20 ml. and treated with Millon's reagent as described, standards being prepared with the same weight of salicylic acid and varying quantities of the *p*-acid.—F. W. Edwards, H. R. Nanji and M. K. Hassan, *Analyst*, 1937, 178.

Colour Test. The mixed mono-, bis-, and tris-azophenols produced by coupling *p*-hydroxybenzoic acid with benzene diazonium chloride are insoluble in sodium carbonate solution while the product from salicylic acid is readily soluble. The ethereal solution of the compounds from *p*-hydroxybenzoic acid acquires a red colour when shaken with sodium hydroxide solution. The test is conducted as follows:—The diazotising solution is prepared by adding a 22.5% *w/v* aqueous solution of sodium nitrite to a solution of aniline 5 g. in hydrochloric acid 13 ml. and water 26 ml., the temperature being kept below 5°, until free nitrous acid is present as indicated by starch iodide paper. A small quantity of the mixture of acids is dissolved in sodium hydroxide solution and cooled below 5°. Excess of the diazo solution is added and after a short time the mixture is acidified and extracted with ether. The ethereal extract is then shaken with sodium carbonate to remove the salicylic acid derivative. On shaking with sodium hydroxide the ethereal layer acquires a red colour. If the acids are extracted from foodstuffs they will be obtained in the form of esters which must be hydrolysed before the test is applied.—S. G. Stevenson and J. C. L. Resuggan, *Analyst*, 1938, 152.

ACIDUM SULPHURICUM

Acidum Sulphuricum (B.P.). Contains not less than 95% *w/w* of H_2SO_4 with a sp. gr. of about 1.84. The B.P.

* If tests II and III are positive, the preliminary oxidation with alkaline permanganate must be carried out before applying this test.

limits the amount of oxidisable impurities present by addition of 0.1 ml. of N/10 potassium permanganate to a cooled mixture of 5 ml. with 20 ml. of water, which should not be decolorised within 5 minutes; and nitrate by 5 ml. with 5 ml. of water not decolorising 0.5 ml. of indigo carmine solution. Acidum Sulphuricum Dilutum, *B.P.*, contains from 9.5 to 10.5% *w/w* of H_2SO_4 , and has a sp. gr. of 1.064 to 1.073. The strong acid of the *U.S.P. XII* contains 94 to 98% *w/w* of H_2SO_4 ; sp. gr. at 25°, about 1.84. The dilute acid contains 9.5 to 10.5% *w/v* of H_2SO_4 ; sp. gr. at 25° about 1.064. The acid of the *Fr. Cx. 1937* contains not less than 95% of H_2SO_4 and has a sp. gr. at 20° of about 1.8385. The dilute acid (sp. gr. at 15°, 1.068) contains 10% H_2SO_4 . Acidum sulfuricum, *P.G. VI*, contains 94 to 98%, Acidum sulfuricum crudum not less than 94%, and Acidum sulfuricum dilutum from 15.6 to 16.3% of H_2SO_4 .

The British Standards Institution has published British Standard Density-Composition Tables for Aqueous Solutions of Sulphuric Acid (*B.S.S. No. 753—1937*) giving the concentration of acid in g. of H_2SO_4 per 100 g. and in g. of H_2SO_4 per 1000 ml. corresponding to densities of 0 to 1.834 for each 2° over the range of 10° to 40°. The tables are designed for use in conjunction with British Standard Density Hydrometers.

Acidum Sulphuricum Aromaticum (*B.P.C.*). Contains 12.2 to 13.5% *w/v* of free and combined sulphuric acid. Assayed by evaporation with excess standard sodium hydroxide solution followed by titration of the dissolved residue with standard sulphuric acid, using methyl orange indicator. The *U.S.P. XI* preparation contained free sulphuric acid and ethylsulphuric acid equivalent to 19 to 21% *w/v* of H_2SO_4 .

Calcii Sulphas Exsiccatus (*B.P.C.*). $\text{CaSO}_4, \frac{1}{2}\text{H}_2\text{O} = 145.1$. The *B.P.C.* specifies the solidifying power; a mixture of 20 g. with 10 ml. of water at 15° to 20° sets in about 3 minutes, the test being performed in a cylindrical container of about one inch diameter; after 3 hours the edges of the moulded mass retain their sharpness of outline and do not crumble under pressure of the fingers.

Ligamentum Calcii Sulphatis (*B.P.C.*). The weight of a length of 4 yards of 2-inch bandage is not less than 2.5 ounces, the fabric alone weighing not less than 85 grains; the other widths should be in proportion; not less than an average of 33 threads in the warp and 19 in the weft, per inch. The bandage should be reasonably free from loose powder and 75% of the weight of the bandage should be plaster of paris which is adherent to the fabric.

Magnesii Sulphas (*B.P.*). $\text{MgSO}_4, 7\text{H}_2\text{O} = 246.5$. The 97.4% standard of the 1914 Pharmacopœia is replaced by a standard of not less than 99.5% and not more than the equivalent of 102% of the pure salt. Assayed by precipitation as magnesium ammonium phosphate with sodium phosphate in ammoniacal solution containing ammonium chloride, filtration after shaking and standing, washing with 2% ammonia solution and final ignition to pyrophosphate. The substance of the *U.S.P. XII* is required to contain

from 40 to 52% of water, and after ignition to the anhydrous salt contains not less than 99.5% of MgSO_4 .

Magnesii Sulphas Exsiccatus (B.P.C.). Contains from 62 to 70% of MgSO_4 , when precipitated as the magnesium ammonium phosphate compound and ignited to pyrophosphate. Magnesium sulfuricum siccatum, *P. Helv. V*, contains about two molecules of water and on heating to a low red heat loses from 22.5 to 25% of water.

Ammonii Persulphas (B.P.C.). $(\text{NH}_4)_2\text{S}_2\text{O}_8 = 228.2$. Contains not less than 98% of the pure substance. Assayed by the method of the *B.P.C.* 34: to 0.5 g. dissolved in 10 ml. of water, 50 ml. of N/10 oxalic acid and 0.2 g. of silver sulphate in 20 ml. of dilute sulphuric acid are added, after heating on a water-bath till evolution of carbon dioxide has ceased the mixture is diluted and the excess oxalic acid titrated with standard potassium permanganate.

Potassii Persulphas (B.P.C.). $\text{K}_2\text{S}_2\text{O}_8 = 270.3$. Assayed by the oxidising action of one equivalent of oxygen upon excess oxalic acid, as in the *B.P.C.* titration for Ammonii Persulphas, it contains not less than 98% of $\text{K}_2\text{S}_2\text{O}_8$.

Sodium, Ammonium and Potassium Persulphates are strong bleaching agents, the last known as Anthion, and the ammonium salts are used in photography to reduce dense negatives—they oxidise and then dissolve part of the silver. On adding barium chloride to a solution of a persulphate there is no precipitation but, on warming, barium sulphate is thrown down.

The ammonium salt is prepared by electrolysis of a solution of ammonium sulphate containing sulphuric acid. In presence of water it yields ozonized oxygen. It bleaches, and has been used as a hand disinfectant and to sterilise sponges.

Potassii Sulphas (B.P.C.). $\text{K}_2\text{SO}_4 = 174.3$. Contains not less than 99% of the pure salt, determined gravimetrically by precipitation and ignition of the barium compound. A 2% solution should not be acid to methyl orange. Potassii Sulfas, *N.F. VII*, contains 99%.

Sodii Sulphas (B.P.). $\text{Na}_2\text{SO}_4, 10\text{H}_2\text{O} = 322.2$. Assayed by weight of the ignited barium salt, it contains not less than 99% and not more than the equivalent of 102% of $\text{Na}_2\text{SO}_4, 10\text{H}_2\text{O}$. The substance of the *U.S.P. XII* contains not less than 99% of the anhydrous salt, after rendering anhydrous at 110° ; loss at 110° , 51 to 57%.

Sodii Sulphas Exsiccatus (B.P. Add. IV). $\text{Na}_2\text{SO}_4 = 142.1$. Loses not more than 5% of its weight at 100° , and then contains not less than 99% of the anhydrous substance. Assayed by precipitation with barium chloride and ignition of the insoluble sulphate. Complies with the tests for purity for Sodii Sulphas using 2/5 of the quantities. The *N.F. VII* substance loses not more than 3% at 100° , and is then of the same purity. Natrium sulfuricum siccatum, *P.G. VI*, contains not less than 88.6% of Na_2SO_4 .

Zinci Sulphas (B.P. Add. I). $\text{ZnSO}_4, 7\text{H}_2\text{O} = 287.5$. Assayed by the process of the British Pharmacopœia Add. I; a solution of

0.4 g. in 120 ml. of water, just acidified with dilute sulphuric acid and mercuric ammonium thiocyanate solution added, is set aside to crystallise; the filtered precipitate is washed with five 10 ml. quantities of diluted ammonium mercuric thiocyanate (1 : 50), and then titrated immediately after the addition of 5 ml. of water, 40 ml. of hydrochloric acid and 5 ml. of chloroform, with M/5 potassium iodate. It contains from 99.5% to the equivalent of 101% of $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$. Zinci Sulfas, *U.S.P. XII*, contains from 55.58 to 61.0% of ZnSO_4 , corresponding to not less than 99% of crystalline substance and is assayed by precipitation as carbonate and ignition to oxide; limit of alkalis and alkali earths weighed as sulphate, 0.5%.

ACIDUM SULPHUROSUM

Acidum Sulphurosum (B.P.C.). Contains not less than 4.5% and not more than 5.5% *w/w* of SO_2 , corresponding to 5.76 to 7.05% *w/w* of H_2SO_3 . Sp. gr. about 1.025. Estimated by oxidation with excess standard iodine and titration with sodium thiosulphate.

Sulphurous acid is a strong reducing agent. For example, many colours are bleached by the sulphurous acid combining with the oxygen of any water present, hydrogen being liberated, which latter forms colourless compounds with the colours. These compounds may then be removed by washing.

The gas compressed in small cylinders was used for room disinfection, but formaldehyde (*q.v.*) is more frequently used now.

Official qualitative and quantitative methods for the determination of sulphurous acid in foods are described in *Methods of Analysis (A.O.A.C., 1940, 463)*.

Sulphur Dioxide in Industry.

Sulphur dioxide is one of the most commonly used gases. Apart from its occurrence in industry in the roasting of ores and the distillation of coal, it is used extensively in refrigeration, fumigation, and for bleaching. It is colourless, but possesses a distinctive odour, whilst some people taste it even more readily at the back of the mouth than they are able to smell it. At one time it was believed that sulphur dioxide in the air of towns did considerable damage, but much of the damage attributed to it may be caused by sulphuric acid, to which it is stated to be oxidised fairly readily. In the neighbourhood of blast furnaces vegetation may be attacked at a distance of several miles, conifers being particularly susceptible. In high concentration it acts as an asphyxiant, but, as generally encountered, it is an irritant. Concentrations of 400–500 parts per million are dangerous even for a short exposure. 20 parts per million will cause coughing in a short time, whilst not more than 10 parts per million can be inhaled for any considerable period. The least detectable odour is stated to be between 3 and 5 parts per million.

Detection and Determination. Three methods are in general use for the determination of sulphur dioxide in air, all of which have been adapted for the particular purpose in hand. For the

detection of comparatively large amounts of the gas, i.e., a concentration of 10 parts per million or more, the air is drawn through a test paper, prepared by soaking in a dilute solution of glycerin containing 1% of potassium iodate and 2% of potassium iodide, drying and using fresh. The colours obtained are compared with standard coloured charts. Sulphur dioxide in the air in amounts down to 1 part per 100,000,000 is determined by drawing a known volume of air, usually over a 24-hour period, through a 1% hyperol solution and determining the increase in acid formed either by titration with N/100 NaOH or by precipitation as barium sulphate. Active sulphur dioxide in the air is determined by exposing cylinders coated with a tragacanth suspension of lead peroxide and determining the quantity of lead sulphate formed.—(*Toxic Gases in Industry*, No. 3, D.S.I.R.)

Sodii Sulphis (B.P.C.). $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O} = 252.2$. Assayed by addition of excess standard iodine solution and titration with sodium thiosulphate, using starch mucilage indicator, a purity of not less than 94% should be indicated. Thiosulphate is limited by absence of turbidity on addition of hydrochloric acid to a 10% aqueous solution.

Sodii Metabisulphis (B.P. Add. IV). $\text{Na}_2\text{S}_2\text{O}_5 = 190.1$. By oxidation with excess of N/10 iodine in acid solution and back titration with N/10 sodium thiosulphate, it contains not less than 90% of $\text{Na}_2\text{S}_2\text{O}_5$. A test for absence of thiosulphate is included.

Sodii Thiosulphas (B.P. Add. I). $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O} = 248.2$. On titration with N/10 iodine, 99 to the equivalent of 101% of $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ is indicated. Sodii Thiosulphas, U.S.P. XII, contains 99% of $\text{Na}_2\text{S}_2\text{O}_3$, determined on the anhydrous substance; loss at 40° to 50°, and afterwards at 100°, 32 to 37%. Natrium thiosulfuricum is official in the P.G. VI.

Decinormal sodium thiosulphate solution is stable for 5 months if prepared with 0.05% NaOH and 0.1% sodium benzoate as preservatives.—J. Ehrlich, *Industr. Engng Chem. (anal. Edn.)*, 1942, 5, 406.

Auri et Sodii Thiosulphas (B.P.C.). $\text{Na}_3\text{Au}(\text{S}_2\text{O}_3)_2 \cdot 2\text{H}_2\text{O} = 526.5$. Should retain its colour, physical properties and solubility when kept in closed phials at 75° for 24 hours. Assayed by the B.P.C. process for Au content by treatment of 0.8 g. in 50 ml. of water with 10 ml. of N/1 sodium hydroxide and 10 ml. of 20 vols. hydrogen peroxide, boiling off excess peroxide and acidifying with hydrochloric acid; the coagulated precipitate of gold is washed, dried, ignited and weighed. A gold content of 37.0 to 37.6% is required.

ACIDUM TANNICUM

Acidum Tannicum (B.P.). Obtained from the galls of various species of *Quercus*; it loses from 6 to 12% of its weight at 100°. Gums, dextrin, sugar and salts are limited by the addition of an equal volume of alcohol to a 20% aqueous solution, and no turbidity is shown on the addition of a half volume of ether. The

U.S.P. XII acid should lose not more than 12% of its weight at 100°.

The identification by chemical methods of drugs containing tannins.—A. H. Ware, *Pharm. J.*, ii/1925, 131.

A review of the tannins in astringent drugs.—A. H. Ware, *Pharm. J.*, ii/1926, 162.

Commercial examination of tannins by comparative methods.—W. B. Forbes, per *Yearb. Pharm.*, 1926, 293.

Garratt (*Drugs and Galenicals*) gives details for the application of the Lowenthal-Proctor method for determination of tannin in drug infusions.

Ammonium molybdate, 10% solution, gives a reddish-brown colour with tannic acid, also gallic acid, pyrogallol and tincture of catechu. May be used for colorimetric assay for tannin and drugs containing it.—J. Rae, *Pharm. J.*, i/1928, 539.

For a general account of the history, chemistry and distribution of the natural organic tannins see *The Natural Organic Tannins* by M. Nierenstein (J. & A. Churchill).

Albumini Tannas (U.S.P. XI). Loses not more than 6% at 100° for 3 hours; ash not more than 0.3%; water-soluble matter not more than 12%; residue insoluble in 1% sodium bicarbonate solution with pancreatin at 40° after drying at 110°, not more than 30%; residue insoluble in acid pepsin mixture at 40°, and after drying at 110°, not more than 40%.

Acetannin (B.P.C.). Loses not more than 3% of its weight at 100°. A limit of the colour produced on adding ferrous tartrate solution to water shaken with the substance is specified and is equivalent to a tannic acid limit of 0.2%. *Acidum Acetyltannicum, U.S.P. XI*, yielded not more than 15% of matter insoluble in 1% sodium bicarbonate solution and dried at 110°; water-soluble matter not more than 6%.

Acidum Gallicum (B.P.C.). $C_7H_6O_5 \cdot H_2O = 188.1$. Loss at 100°, not more than 10%. A 5% solution should be not more than faintly yellow and does not precipitate with gelatin or albumen solutions. The *N.F. VII* allows a 12% loss at 100° and 0.1% of ash.

Catechu (B.P.). The substance dried at 100° yields not more than 25% of water-insoluble matter. Loss at 100°, not more than 10%. Alcohol-insoluble matter dried at 100° and containing not more than occasional starch grains, not more than 30%. Ash, not more than 8%. Gambir, *N.F. VII*, yields not less than 70% of water-soluble extractive and not less than 60% of alcohol-soluble extractive; acid-insoluble ash limit, 0.5%.

Chloroform extractives not green.—Kay and Oldham, *Pharm. J.*, i/1938, 663.

Intensity of colour in chloroformic extract depends upon the particular sample rather than upon age.—R. E. Wagg, *Pharm. J.*, ii/1938, 27.

Catechu Nigrum (B.P.C.). Alcohol extractive, not less than 60%. Ash, not more than 8%.

Galla. The following tests for purity of Aleppo Galls are recommended by the Sub-Committee on Crude Drugs of the Committee on Pharmacy and Pharmacognosy:—Contains not more than 1% of foreign organic matter; ash, not more than 3%. Transfer 0.1 g. in No. 60 powder to a glass-stoppered vessel of about 300 ml. capacity. Add 100 ml. of boiling water, shake well, allow to stand for ten minutes, and cool quickly to about 20°. Add 50 ml. of N/10 iodine and 40 ml. of N/10 sodium carbonate. Shake gently, allow to stand for ten minutes, add 15 ml. of N/1 sulphuric acid and titrate the excess of iodine with N/10 sodium thiosulphate, using mucilage of starch as indicator; the iodine absorbed is equivalent to not less than 23 ml. of N/10 iodine.—(*British Pharmacopœia Commission Report*, No. 13, September 1939.)

Kino (B.P.C.). Extractive to boiling water, not less than 75%. Ash, not more than 2.5%. The *N.F. VII* requires Kino to yield not less than 60% of alcohol-soluble extractive and not less than 75% of water-soluble extractive.

Tests for Identity and Purity. The following tests for East Indian, Malabar, Madras or Cochin Kino are recommended by the Sub-Committee on Crude Drugs of the Committee on Pharmacy and Pharmacognosy:—To an aqueous solution add test-solution of ferric chloride; a dark green precipitate is produced. To an aqueous solution add solution of sodium hydroxide; a reddish-violet colour is produced. To 5 ml. of a filtered 1% solution in cold water, add 2 ml. of *N/10* iodine; a slight precipitate is produced; add 0.5 ml. of dilute solution of ammonia; the precipitate dissolves (distinction from butea kino). To 5 ml. of a filtered 1% solution in cold water, add 2 ml. of *N/10* iodine; a slight precipitate is produced; boil for one minute, cool, and add 0.5 ml. of dilute solution of ammonia; the precipitate is insoluble (distinction from eucalyptus kino). **Tests for Purity.**—Ash, not more than 2.5%. Yields not less than 75% of extractive soluble in hot water, as determined by the following method:—stir 1 g. in powder with 50 ml. of boiling water, and decant the liquid through a filter into a 200-ml. flask; stir the residue with two further quantities of 50 ml. of boiling water, decanting the liquids through the filter; transfer the insoluble residue to the filter and wash it with hot water; cool the filtrate and washings and make up to 200 ml. with water; evaporate 50 ml. to dryness in a flat-bottomed shallow dish and dry at 100°.—(*British Pharmacopæia Commission Report*, No. 13, September 1939).

Kino Eucalypti (B.P.C.). Alcohol (90%) extractive, not less than 80%. Ash, not more than 3%.

ACIDUM TARTARICUM

Acidum Tartaricum (B.P.). $C_4H_6O_6 = 150.0$. Loses not more than 1% at 100° and then contains 99.5% of the pure substance. Acidum Tartaricum, *U.S.P. XII*, contains 99.7% of $H_2C_4H_4O_6$, when dried over sulphuric acid for 5 hours.

Detection in Syrups and Lemonades. Dilute 100 ml. of the liquid with 20 ml. of water and filter into a 300 ml. test-glass. Add 20 ml. of strong solution of calcium acetate, made by dissolving $CaCO_3$, 32 g. in glacial acetic acid 120 ml. and diluting to 1 litre with distilled water. Mix, stir well, and set aside for 72 hours. In presence of tartaric acid an evident crystalline deposit will be seen which is identified by micro-examination. Confirm by applying Denigé's Test (resorcin and sulphuric acid).—per *Yearb. Pharm.*, 1926, 179.

Determination of Tartaric Acid. About 0.3 g. of the acid is added to a flask containing 1 g. of potassium iodate, a few drops of water and 80 ml. of concentrated sulphuric acid, and the mixture is heated for about 30 minutes until most of the iodine is expelled. Water is added and the last traces of iodine are removed by boiling. By estimation of the remaining potassium iodate (by adding potassium iodide to an aliquot portion and titrating with thiosulphate) the amount of tartaric acid can be calculated from the following equation:—

—*J. chem. Soc. Abstr.*, ii/1924, 73.

Determination as Lead Tartrate. Lead tartrate is quantitatively precipitated from solutions containing tartrates, neutralised to phenolphthalein, by means of 5% lead nitrate solution, of which about 15 ml. is required for 2 g. of acid. After standing 2 hours the precipitate is collected on a Gooch crucible, washed, dried at 105°, and weighed. 1 g. of lead tartrate corresponds to 0.423 g. of $C_4H_6O_6$.—C. H. Manley, *Analyst*, 1937, 526.

Garratt (*Drugs and Galenicals*) recommends the method of King (*Analyst*, 1933, 135) for the determination of tartaric acid in pharmaceutical preparations, in which calcium racemate is separated in dilute acetic and hydrochloric acids.

An official quantitative method for the determination of tartaric acid in baking powders is described in *Methods of Analysis (A.O.A.C., 1940, 188)*.

Potassii Tartras (*B.P.C.*). $C_8H_8O_{12}K_4 \cdot H_2O = 470.5$. Contains not less than 99% of $C_8H_8O_{12}K_4 \cdot H_2O$. Assayed by titration of the alkaline residue, on gentle ignition, with standard sulphuric acid to methyl orange.

Potassii Tartras Acidus (*B.P.*). $C_4H_5O_6K = 188.1$. The substance dried at 100° contains not less than 99.5% of the pure compound. Loss at 100° , not more than 1%. Assayed by titration of the boiling solution with N/5 sodium hydroxide to phenolphthalein. Potassii Bitartras, *U.S.P. XII*, contains 99.5% of $KHC_4H_4O_6$ after drying at 100° . The *Fr. Cx.* 1937 substance contains 99% of the pure salt and loses not more than 1% at 100° .

Cream of Tartar Substitutes. These are usually calcium acid phosphate. A sample examined by Evans was a mixture of cream of tartar with sodium acid sulphate, but in such proportion that the whole of the tartaric acid would be liberated with the cream of tartar in solution, with an excess of about 10% $NaHSO_4$ still remaining. Another sample was a mixture of "dry" calcium acid phosphate and sodium chloride.

Sodium acid pyrophosphate, $Na_2H_2P_2O_7$, is also used as the acidic constituent of baking powders in place of tartaric acid and cream of tartar.

Sodii et Potassii Tartras (*B.P.*). $C_4H_4O_6NaK \cdot 4H_2O = 282.2$. By titration with standard sulphuric acid of the carbonised alkaline residue, using methyl orange as indicator, a purity of not less than 99% and not more than the equivalent of 104% should be found. Potassii et Sodii Tartras, *U.S.P. XII*, loses 21 to 26% of water at 150° , and then contains not less than 99% of the pure anhydrous substance. A test for limit of ammonium compounds is included.

ACONITUM

Aconitum (*B.P.*). The dried root of *Aconitum Napellus*; should contain not more than 2% of other organic matter. The Pharmacopœia states that there is no trustworthy chemical method of assaying the root, and does not consider the drug sufficiently important medicinally to include a biological method. Aconitum, *N.F. VII*, contains not more than 5% of its stems and not more than 2% of other foreign organic matter. 0.1 g. possesses an activity equivalent to not less than 0.150 mg. of reference aconitine when extracted by the method for Tinctura Aconiti, *N.F. VII*, and administered subcutaneously to guinea-pigs. Pulvis Aconiti I.A. is adjusted, by dilution with rice starch if necessary, to contain 0.5% of total alkaloids.

Aconiti Radix of the 1914 Pharmacopœia was assayed for ether-soluble alkaloids of which it was required to contain not less than 0.40%. A tincture was prepared from 10 g. by maceration and percolation with 75% alcohol, and was then evaporated to dryness at a temperature not above 60° ; a filtered solution of the residue dissolved in 5 ml. of N/10 sulphuric acid and 20 ml. of water and washings was made ammoniacal with 2 ml. of solution of ammonia and shaken for one minute with 25 ml. of ether; after evaporation the aqueous liquid was extracted with three subsequent portions of 20 ml. of ether; the ethereal solutions, filtered and

evaporated to dryness, were dried at 60° and the residue titrated with N/20 sulphuric acid, using cochineal as indicator. Tuber Aconiti, *P. Helv. V*, consists of the roots of *Aconitum Napellus* dried rapidly at about 40° and then for one hour at 50° and containing not less than 0.8% of alkaloid. The powder for administration is adjusted with lactose to contain 0.5% of alkaloid.

Assay. The method is based on a determination of the benzoic acid produced by the hydrolysis of the alkaloids, and therefore determines aconitine plus benzoylaconine but not aconine. The total alkaloids are first determined, after extraction in the usual way, by the method of indirect titration, and the solution is evaporated practically to dryness in a current of air on the water-bath. 10 ml. of N/2 alcoholic potash is added, and the mixture refluxed for two hours, and evaporated to dryness. The residue is dissolved in water, acidified with sulphuric acid, and shaken out into a mixture of 80 ml. of light petroleum and 20 ml. of ether for some hours. 80 ml. of the ethereal layer is then evaporated in a current of air, the residue dried *in vacuo* to remove acetic acid, and then titrated with N/100 sodium hydroxide, using a micro-burette.—W. A. van Bronkhorst, *Pharm. Weekbl.*, 1935, 1056.

The Poisons Sub-Committee of the Society of Public Analysts have found that more consistent results were obtainable when assays were based on total alkaloidal content rather than upon the ether-soluble portion. By comparison with biological methods, it was concluded that the chemical assay for total alkaloids generally gives good indication of toxicity, but it should not be assumed that the chemical determination of total alkaloids will give more than an approximate measure of the therapeutic efficacy of the drug. **Recommended Method:**—Shake 10 g. of the drug in No. 60 powder in a suitable stoppered percolator with 100 ml. of ether-chloroform mixture (3 : 1) and allow to stand 15 minutes. Add 5 ml. of dilute solution of ammonia and shake for 1 minute at 10-minute intervals during 1 hour. Allow the liquid to percolate into a separating funnel. When the liquid ceases to flow, pack the drug firmly and continue percolation with mixed solvent until complete extraction of the alkaloids is effected. (Test for complete extraction by evaporating 2 ml. of percolate, dissolving the residue in a few drops of 0.1 N sulphuric acid and adding a few drops of 0.1 N iodine; no precipitate or turbidity should be formed.) To the percolate add 30 ml. of N sulphuric acid, or sufficient to render it faintly acid. Shake, allow to separate and transfer the lower layer to another separating funnel A. Complete the extraction of the alkaloids from the organic solvent, using 10 ml. portions of 0.1 N sulphuric acid and testing for complete extraction by the iodine test. Wash the mixed solutions in A with about 10 ml. of chloroform, and run off the latter to a second separating funnel B, containing 20 ml. of 0.1 N sulphuric acid. Shake, allow to separate and reject the chloroform. Wash the liquid in funnel A with two further 5 ml. portions of chloroform, transferring each in turn to funnel B, washing, and rejecting the chloroform. Transfer the acid liquid from funnel B to funnel A, make just alkaline with dilute solution of ammonia and add 2 ml. excess. Shake with successive portions of chloroform until complete extraction is effected, washing each chloroform extract with the same 20 ml. of water. Distil off the chloroform, add 2 ml. of absolute alcohol to the residue and evaporate at not more than 60°. Dry at a temperature below 60° for 30 minutes. Dissolve the residue in 2 ml. of neutral 95% alcohol, warm to dissolve, add 20 ml. of 0.02 N sulphuric acid and 10 ml. of water, cool and titrate with 0.02 N sodium hydroxide, using methyl red indicator. 1 ml. of 0.02 N acid = 0.01291 g. of alkaloids calculated as aconitine.—*Analyst*, 1942, 289.

Determination of Aconitine in Preparations. Aconitine cannot be separated from benzoylaconine by any usual method for isolating alkaloids, and the following assay depends on the extraction of the two compounds with ether from a buffered solution and calculation of the amount of aconitine present from a study of their dissociation constants. To 10 ml. of the liquid extract or 100 ml. of the tincture add 1 ml. of 10% sulphuric acid and evaporate the alcohol on a steam-bath. Add about 20 ml. of water, filter off the insoluble residue, washing the filter paper with small quantities of water and finally with one or two portions of acidified water. Shake out with ether, rejecting the ether. Add 10% ammonium hydroxide until slightly alkaline to litmus and completely extract the alkaloids with ether. To the combined ethereal extracts add 10 ml.

of N/100 acid, evaporate the ether, and titrate with N/100 alkali using methyl red as indicator. Each ml. of N/100 acid is equivalent to 6.45 mg. of total alkaloids calculated as aconitine. Transfer the neutral solution to a separator containing 50 ml. of the buffer solution (0.0159 N ammonium hydroxide and 0.75 N ammonium chloride) and extract with four successive portions of ether, each of 25 ml., shaking each time for about 10 minutes. Again add 10 ml. of standard acid to the combined ethereal extracts, evaporate the ether and titrate the excess acid as before. The weight in mg. of aconitine, A, is given by the equation $A = 7.236y - 0.1106h$, where y = ml. of standard acid used, and h = total alkaloids.—G. Baker and C. B. Jordan, *J. Amer. pharm. Ass.*, 1936, 291.

Farr and Wright found in aconite extract an average of 0.43% total alkaloid. The amount in the root is about twice that in the leaf. They found in dry root extract from 1.2 to 6%, English root being the best. A method of making the extract is outlined. The average yield of the dry extract was 25.9%, the ether-soluble alkaloid in this averaging 1.95%. Foreign root yielded 30% with an average of only 0.68% ether-soluble alkaloid. A standard of 1% proposed. The dose of this extract would be $\frac{1}{2}$ to $\frac{1}{4}$ grain. Foreign root is very mixed owing to mode of collection.—*Pharm. J.*, i/1913, 216.

Fluidextractum Aconiti (N.F. VII). 1 ml. has a potency equivalent to from 1.4 mg. to 1.6 mg. of reference aconitine, when assayed by the biological method used for tincture of aconite.

Tinctura Aconiti (B.P.C.). An unstandardised tincture prepared by percolation of 150 g. of powdered root with 70% alcohol to 1 litre. Alcohol content, 67 to 69% *v/v* of ethyl alcohol. The tincture of the B.P. '14 was standardised to contain 0.04% of ether-soluble alkaloids. Tinctura Aconiti I.A., prepared with 70% alcohol, contains 0.05% of total alkaloids.

Assay of Aconite Tincture and Liniment. Loss of time caused by filtering the acid liquid can be minimised thus:—Evaporate 15 ml. of liniment or 100 ml. of tincture at low temperature to remove bulk of the alcohol. Add 5 ml. of 10% sulphuric acid. Shake with 20 ml. of petroleum ether, rinse same with water and extract with ether after making alkaline. Evaporate the ether extracts and titrate.—E. J. Chappel and N. L. Allport, *Yearb. Pharm.*, 1920, 444.

Biological Methods of Assay.

Tinctura Aconiti (N.F. VII), when assayed biologically on guinea-pigs, is required to possess a potency in 1 ml. equivalent to not less than 0.140 mg. and not more than 0.160 mg. of reference aconitine. In the assay, the guinea-pigs must all be from one colony and be kept under identical conditions. The doses are determined of reference aconitine and of the sample being tested, which will kill not more than seven and not less than three of groups of ten animals, within 6 hours. The doses are considered equivalent if the mortalities in each case differ by not more than two animals. The accuracy of this standardisation is stated to be $\pm 20\%$.

Toxicity Test on Mice. Dyer (*Quart. J. Pharm.*, 1930, 626) has suggested the determination of the toxicity by injection of a tincture into mice to find the dose which kills fifteen out of thirty mice. The toxicity, however, cannot be expressed in terms of this dose since when one sample is tested in different laboratories the dose differs (see Broom, Burn, Gaddum, Trevan and Underhill, *Quart. J. Pharm.*, 1932, 33). Each sample must, therefore, be compared for toxicity with a standard, which can be prepared by mixing a series of ten samples of the dried and powdered root of *Aconitum Napellus*. This standard would have to be distributed from some central institution. By comparing a tincture prepared from the sample with that prepared from the standard and finding the dose of each which kills fifteen out of thirty mice, then if the unknown sample is more toxic than the standard, it can be adjusted by dilution so as to be equal to the standard.

Aconitina (B.P.C.). $C_{34}H_{47}O_{11}N = 645.4$. M.p. when heated rapidly, 196° to 200° , acetic acid being evolved. The amount of pseudaconitine present is limited: 10 mg. dissolved in and evaporated with 5 drops of fuming nitric acid produces a yellow residue which should show no red colour on moistening

with N/2 alcoholic potassium hydroxide. Aconitina, *U.S.P. X*, dissolved in water with a little acetic acid and injected under the skin of the abdomen of guinea-pigs, had a minimum lethal dose of from 0.000000055 g. to 0.000000065 g. for each gramme of body weight of guinea-pig, two-thirds of the number of guinea-pigs being tested dying within 6 hours. Aconitinum, *P. Helv. V*, contains not less than 99.1% of $C_{34}H_{47}O_{11}N$ and is determined by titrating a solution in a known excess of N/10 hydrochloric acid with N/10 sodium hydroxide using methyl orange.

Aconitine gives a reddish-violet colour when warmed with resorcinol and sulphuric acid, and the liquid becomes colourless with a blue fluorescence when made alkaline with strong sodium carbonate solution; a residue of total alkaloids of aconite gives the same reddish-violet colour, but when made alkaline a deep purple colour is produced with a green fluorescence.—C. Bruegas, *Ann. Falsif.*, 1932, 25, 147.

Pseudaconitine. A crystalline alkaloid obtained from Indian (or Nepaul) aconite, *A. laciniatum*, melts at 201° and has the constitution of acetyl-veratroyl-pseudaconine.

Most of the Japanese aconite plants contain several isomers and closely related aconitines. Methods of extraction and isolation of 6 isomers.—*Yearb. Pharm.*, 1925, 48, 49.

ACRIFLAVINA

Acriflavina (*B.P. Add. I*). A 2% solution in water at 30°, and also a 0.2% solution in normal saline at 30°, should remain clear and free from sediment on standing in the dark for 24 hours at 15° to 20°. Residue on ignition with sulphuric acid, not more than 1%. Acriflavina, *N.F. VII*, a mixture of 2 : 8-diamino-10-methyl-acridinium chloride and 2 : 8-diamino-acridine and similar to euflavine, after drying to constant weight at 100°, contains 13.3 to 15.8% of Cl. Loss at 100°, not more than 7%. Residue on ignition with sulphuric acid, not more than 3.5%; matter insoluble in warm water, not more than 0.5% when dried at 100°. Assayed by digestion with potassium permanganate, sulphuric acid and silver nitrate solution, decolorisation with hydrogen peroxide and subsequent gravimetric estimation of the precipitated silver chloride. Acriflavinae Hydrochloridum, *N.F. VII*, loses not more than 7% over sulphuric acid, and then contains 23 to 24.5% of Cl; residue on ignition with sulphuric acid, not more than 1%.

Assay. The following process for the total diaminoacridines in acriflavine is recommended by the Sub-Committee on Synthetic Chemicals of the Committee on Pharmaceutical Chemistry:—Dissolve about 2 g., accurately weighed, in 250 ml. of water, and dilute with water to 750 ml. Adjust the reaction of the solution, at room temperature, by the addition of N/1 hydrochloric acid, until faintly acid to Congo-red paper, and then add 5 g. of sodium acetate. Add 50 ml. of M/10 potassium ferricyanide, stirring during the addition, allow to stand for ten minutes, filter through a Buchner funnel, and wash the precipitate with three successive quantities of 50 ml. of water. Mix the filtrate and washings, and add separately 10 ml. of hydrochloric acid, 10 g. of sodium chloride, 1 g. of potassium iodide, and 3 g. zinc sulphate, dissolved in 10 ml. of water, mixing after each addition. Allow to stand for three minutes, and titrate the liberated iodine with N/10 sodium thiosulphate, using mucilage of starch as indicator. When the titration is nearly complete, allow to stand for a further three minutes, and then complete the titration. Determine by :

control experiment the number of ml. of N/10 sodium thiosulphate equivalent to 50 ml. of the M/10 potassium ferricyanide. Calculate the volume of M/10 potassium ferricyanide required by the acriflavine; each ml. of M/10 potassium ferricyanide is equivalent to 0.08883 g. of $C_{14}H_{14}N_2Cl.HCl$.—(*British Pharmacopæia Commission Report*, No. 12, May 1939).

Commercial acriflavine consists of a mixture of approximately equal parts of the hydrochloride of 2:8-diaminomethylacridinium chloride and diaminoacridine dihydrochloride. The solubility of acriflavine depends on the proportions in which the two compounds are present. The methylacridinium compound has a solubility of 0.4%, and the diaminoacridine dihydrochloride of 0.3%. A synthetic mixture of equal parts has a solubility of 1%. The difference between this figure and that for acriflavine is due to the existence of diaminoacridine hydrochloride in an unstable but more soluble form. Mixtures of approximately equal parts of the two substances obtained by adding hydrochloric acid to a warm concentrated solution containing them have a solubility in agreement with the B.P. figure of 1 in 3.—*M. Gailliot, Quart. J. Pharm.*, 1934, 63.

Solubility. The solubility increases with increasing proportions of diaminoacridine dihydrochloride up to 50%. On standing, most solutions precipitate owing to hydrolysis. An acidity corresponding to more than about 1% of HCl results in a lowering of the solubility.—*G. F. Hall and A. D. Powell, Quart. J. Pharm.*, 1936, 510.

From commercial samples of acriflavine containing 30 to 40% of diaminoacridine, a product containing only about 12% of this material may be obtained by treatment with caustic soda. Recrystallisation of the partly purified product from water then suffices to remove the whole of the remaining diaminoacridine.—*J. Marshall, Quart. J. Pharm.*, 1934, 514.

Results of Analysis of some Commercial Flavines

| Samples of Acriflavine | "Total flavines" (ferricyanide) as acriflavine per cent. | Acriflavine from chloride (uncorr.) per cent. | Diamino- acridine dihydrochlor. (alkali pptn.) per cent. |
|---------------------------|--|--|--|
| A | 97.2 | 96.5 | 35.2 |
| B (1) | 96.1 | 96.8 | 11.0 |
| B (2) | 98.6 | 96.7 | 20.0 |
| C | 93.6 | 94.6 | 42.0 |
| Samples of Euflavine | "Total flavines" (ferricyanide) as euflavine per cent. | Euflavine from chloride corrected for NaCl per cent. | Diamino- acridine monohydro- chlor. (alkali pptn.) per cent. |
| A | 91.4 | 94.2 | 33.5 |
| B (1) | 93.9 | 97.2 | — |
| B (2) | — | — | 5.5 |
| C | 87.5 | 95.6 | 25.5 |
| Samples of Proflavine | "Total flavines" (ferricyanide) as proflavine (sulphate) per cent. | Proflavine (sulphate) from sulphate per cent. | Proflavine (sulphate) (alkali pptn.) per cent. |
| A | 92.4 | 89.7 | 92.1 |
| B | 97.7 | 94.4 | — |

—*G. F. Hall and A. D. Powell, Quart. J. Pharm.*, 1934, 522.

Determination of Flavine Compounds. For determining flavine compounds in preparations the ferricyanide method must be modified as follows:—

General Method. The solution derived from preliminary treatment, and containing from 0.02 to 0.2 g. of the diaminoacridine derivative, is diluted to approximately 200 ml. and rendered faintly acid to Congo-red paper. 1 g. of sodium acetate crystals is added, followed by sufficient excess of M/50 potassium ferricyanide with stirring during the addition (10 to 30 ml. according to the amount required for precipitation). The mixture is allowed to stand for 30 minutes and then filtered through a Buchner funnel. The precipitate is washed with three successive quantities of 10 ml. of water, and to the combined filtrate and washings 5 ml. of hydrochloric acid (sp. gr. 1.16), 1 g. of sodium chloride, 0.5 g. of potassium iodide and 5 ml. of 30% zinc sulphate solution are added, with mixing after each addition. After standing for 3 minutes, the liberated iodine is titrated with N/100 sodium thiosulphate. A blank determination is also made, using the same amount of M/50 ferricyanide reagent. 1 ml. of M/100 ferricyanide precipitated is equivalent to 0.00888 g. of acriflavine, 0.00779 g. of euflavine, or 0.00921 g. of proflavine.

Dressings. Extract 20 g. or other convenient quantity, in a Soxhlet extractor, with alcohol (95%) slightly acidified with hydrochloric acid (250 ml. of alcohol and 2 ml. of dilute hydrochloric acid). Usually 3 hours are required. Transfer the extract to a beaker, add 50 ml. of water, evaporate to remove the bulk of the alcohol, and add, whilst still hot, 25 ml. of chloroform. Mix thoroughly, cool, transfer to a separator, allow to separate and then complete the removal of fats by extraction with chloroform (25, 25 ml.). Wash these combined extracts with two successive quantities of 10 ml. of water, made slightly acid with one or two drops of dilute hydrochloric acid. If emulsions are formed, break with a little alcohol. Evaporate the united aqueous solutions to low volume to remove alcohol, dilute to about 200 ml., add dilute sodium hydroxide solution until slightly acid to Congo-red paper, and complete as the general method.

Pessaries and Emulsions Containing Fat or Oil. A suitable quantity of the preparation (generally 25 to 50 g.) is treated with about 50 ml. of chloroform to dissolve the basis. The solution is then transferred to a separator and extracted with 20 ml. of water containing 2 ml. of dilute hydrochloric acid, followed by two extractions with 10 ml. of water containing 0.5 ml. of dilute hydrochloric acid. The combined acid-aqueous extracts are washed with 25 ml. of chloroform: any medicament taken into the chloroform is re-extracted with 10 ml. of water containing 1 or 2 drops of dilute hydrochloric acid. If emulsions form, they can be broken by the addition of alcohol. The combined acid-aqueous extracts are transferred to a beaker, evaporated sufficiently to remove alcohol if present, cooled, and diluted to about 200 ml. Sodium hydroxide is added until the liquid is only slightly acid to Congo-red paper, and the estimation completed by the general method.

The method can also be applied to preparations containing glycerin and gelatin but errors of 5 to 10% arise owing to the presence of reducing substances. —G. F. Hall and A. D. Powell, *Quart. J. Pharm.*, 1937, 486.

Methylene Blue Determination of Acridines. Acridines and their salts are precipitated by picric acid. By adding an excess of picric acid, removing the precipitate, and estimating the amount of acid unused by titration with methylene blue, the acridine may be determined. The reagents required are (1) N/100 picric acid, prepared by dissolving 2.29 g. of picric acid in water and diluting to 1 litre, and (2) N/1000 methylene blue, prepared by dissolving 3.8 g. of methylene blue in water containing about 3 ml. of chloroform and diluting to 1 litre to produce an approximately N/100 solution; N/1000 methylene blue is prepared by dilution and standardisation against N/1000 picric acid, which is made by dilution of the above N/100 solution. **Methods.**—(a) 2:8-Diaminoacridine (base). Dissolve about 0.1 g. in 30 ml. of 0.5% acetic acid in a 200 ml. graduated flask. Add a measured excess of N/100 picric acid (0.1 g. requires theoretically 47.85 ml.) and adjust the volume to 200 ml. with water. Mix well and keep for at least an hour in a refrigerator. An aliquot portion (20 ml.) of the filtrate is transferred to a separating funnel containing chloroform and calcium carbonate, and N/1000 methylene blue run in from a burette. The methylene blue picrate formed is extracted by the chloroform, on shaking, leaving the aqueous layer yellow. On continuing the titration, with frequent changes of chloroform, the yellow colour gradually fades and the end-point is taken when one drop of methylene blue solution gives a faint blue colour, which is not removed by the chloroform, to the almost

colourless, aqueous layer. (b) *Proflavine*. 0.1 to 0.2 g. of sample (0.1 g. theoretically requires 32.56 ml. of N/100 picric acid) is used, and it is advisable to keep the reaction mixture in a refrigerator for at least four hours, otherwise the procedure is the same as for the base. Details are also given for combined determinations of base and sulphate. (c) 2 : 8-Diamino-10-methylacridinium chloride. Determine as for proflavine, using 0.1 to 0.2 g. of sample (0.1 g. theoretically requires 38.46 ml. of N/100 picric acid). In this case the picrate precipitated is orange and amorphous, contrasted with the yellow, crystalline appearance of 2 : 8-diaminoacridine picrate. Chloride may be determined by applying Volhard's method to a portion of the filtrate, providing only a small excess of picric acid has been used, and the precipitated silver chloride and thiocyanate are filtered off before the end-point is reached. (d) *Acriflavine* (and similar mixtures of acridine hydrochlorides). The total "flavine" content can be determined by adding picric acid to a solution and titrating the excess of picric acid. The result is preferably expressed as percentage of diamino-methylacridinium chloride (euflavine). The chloride content may be determined by Volhard's method. An approximate separation of the two constituents may be effected by the silver oxide method of Gailliot (*Quart. J. Pharm.*, 1934, 63). Approximately 0.5 g. of sample is dissolved in 30 ml. of water and added to freshly prepared silver oxide. The mixture is stirred for five minutes, filtered through sintered glass, and the precipitate washed with 5 ml. of water, which is added to the filtrate. The filtrate contains diamino-methylacridinium hydroxide. After slight acidification with hydrochloric acid it is treated with a known excess of N/100 picric acid (120 ml.), and the solution made up to volume. After standing for four hours the picrate is filtered off and the excess picric acid determined. The precipitate containing the diaminoacridine is removed from the filter and treated with 50 ml. of 4% acetic acid. To the mixture is added 80 ml. of N/100 picric acid and the volume of solution adjusted to 250 ml.; after filtration the excess of picric acid is determined.—A. Bolliger, *Quart. J. Pharm.*, 1940, 1.

Euflavina (*B.P.C.*). Should contain not less than 93% of the pure substance, calculated with reference to the sample dried at 120° at which temperature it should lose not more than 7% of its weight. A 0.2% solution should remain clear when kept in the dark for 24 hours. Assayed by the recommended *B.P.* process for acriflavine (*see* p. 49). 1 ml. of M/10 potassium ferricyanide is equivalent to 0.07788 g. $C_{14}H_{14}N_3Cl$. Chlorhydrate de Diamino-Acridine is official in the *Fr. Cx.* 1937.

Linteum Euflavinæ (*B.P.C. Supp. I*). Contains not less than 0.075% of euflavine, $C_{14}H_{14}N_3Cl$. Assayed by the method described for dressings on p. 51.

Proflavinæ Sulphas (*B.P. Add. IV*). $C_{13}H_{11}N_3 \cdot H_2SO_4 = 307.19$. Loses at 100°, not more than 10% and then contains not less than 98% of the pure salt. 1 g. in 250 ml. of water at 35°, and 0.2 g. in 100 ml. of water at 50° and at 20° with 0.9 g. of sodium chloride, remain clear and free from sediment when kept in the dark for 24 hours at 15° to 20°. Residue on re-ignition with sulphuric acid, not more than 1%. Assayed by precipitation with M/10 potassium ferricyanide as recommended for the *B.P.* assay of acriflavine on p. 49.

ADEPS LANÆ

Adeps Lanæ (*B.P. Add. I*). M.p., 34° to 40°. Acid value not more than 1. Saponification value (2 hours boiling), 94 to 106. Iodine value, to 32. Loss at 100°, not more than 0.5%. Ash not more than 0.15%. Complies with the revised limit test for

chlorides described under Adeps. The *U.S.P. XII* substance melts between 38° and 42°; loss on a water-bath, not more than 0.5%; ash, not more than 0.1%; acids in 10 g. equivalent to not more than 2.0 ml. of N/10 sodium hydroxide; iodine value, 18 to 36.

Alcoholia Lanæ (*B.P. Add. VI*). Assayed by precipitation with digitonin solution at 60°, collecting the residue on a Gooch crucible and drying at 100°, it contains not less than 28% of cholesterol. M.p. not below 54°; acid value not more than 3; saponification value not more than 12; acetyl value 130 to 140. Loses not more than 0.5% when heated at 100° for 1 hour; ash not more than 0.3%. An 8% solution in neutral alcohol (90%) is not alkaline to phenolphthalein.

Adeps (*B.P. Add. I*). After the preliminary treatment described in the *B.P.*, by melting 10 to 20 g., cooling until a turbidity appears, stirring until homogeneous, and setting aside for five hours with the container in water at 10° to 12°, or in running water for twenty-four hours, it should melt between 34° and 41°. Refractive index at 60°, 1.452 to 1.455. Acid value, not more than 1.2. Saponification value, 192 to 198. Unsaponifiable matter, not more than 0.5%. Iodine value, 52 to 66. The melting-point of the lard stearin obtained by the matter insoluble in ether at 16° to 20° should be not lower than 63° and is usually higher than 63.4°; a low melting-point indicates the presence of beef stearin. Sesame oil is tested for by the general pharmacopœial test with hydrochloric acid containing 1% of sucrose, giving no pink colour on shaking and setting aside for 5 minutes; and cottonseed oil by the general *B.P.* test of mixing with an equal volume of a mixture of equal parts of amyl alcohol and 1% solution of precipitated sulphur in carbon disulphide and immersing the container in boiling water for 30 minutes, when no red colour develops. A limit of chlorides in which the turbidity with silver nitrate produced by the filtrate from 1 g. boiled with alcohol, diluted and acidified, is not greater after 5 mins. standing than that produced by 0.5 ml. of N/50 hydrochloric acid similarly treated, is included. Adeps, *U.S.P. XII*, melts at 36° to 42°, after melting just sufficiently to draw into a capillary, cooling at 10° for 24 hours or at 0° for 2 hours, and the point taken when melted just sufficiently to rise in the capillary when heated in a water-bath at about 0.5° rise per minute. It is tested for cottonseed fats by warming 5 ml. with an equal volume of alcohol containing 0.05 g. of silver nitrate and one drop of nitric acid on a water-bath for 5 minutes, when no red or brown colour nor brown line of contact develops. The microscopical appearance of the separated stearin, which should appear as flat, rhomboidal plates with one oblique end and irregularly placed, and not as cylindrical sharp-ended rods or needles in fan-shaped clusters, excludes beef fat. Saponification value, 195 to 203; iodine value, 46 to 70; solidification point of the fatty acids, 36° to 42°. The *Fr. Cx.* 1937 describes a test for cottonseed oil (limit 5%) in lard,

when the fat and a silver nitrate solution in alcohol with nitric acid, kept in the water-bath for 10 minutes, does not become red or brown.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined lard as the rendered fresh fat from hogs, in good health at the time of slaughter, free from rancidity and containing not more than 1% of substances other than fatty acids and fats. *Leaf lard*: lard rendered at a moderately high temperature from the internal fat of the abdomen of the hog, excluding that adherent to the intestines, and with iodine number not greater than 60. *Neutral lard*: lard rendered at low temperatures.—*S.R.A., F.D. No. 2, Rev. 5, Nov. 1936.*

Lard is very fully standardised because it is very easily adulterated and if any standards at all are given they should be as many as will give the greatest assurance that genuine lard is being used. The directions for the treatment of the sample before determining the melting-point are complicated but do not go far enough because the method adopted for the preliminary treatment may seriously affect the result. The melting-point range does not include all genuine lards.—*N. Evers, Pharm. J., i/1933, 196.*

A method for the approximate determination of some of the unsaturated minor component acids of pig and other fats is by separation of the fatty acids as lithium salts from acetone. The yield of ether-insoluble bromo-derivative products is determined and from this the percentage of C_{20-22} acids is obtained. The iodine and thiocyanogen values of the acids are determined and from the results the total saturated oleic and linoleic acids are found.—*T. P. Hilditch and W. H. Pedelty, Analyst, 1939, 640-647.*

Extraordinary variations occur in lard according to the age of the pig and the character of the food. Iodine value, refractive index, Bömer value, microscopical appearance of crystals, are all examined for various lards and mixtures.—*R. W. Sutton et al., Analyst, 1940, 623-636.*

Sevum (B.P.). M.p., 45° to 50° (by introducing into a capillary 0.75 to 1 mm. diameter, and, if by melting, cooling at 0° for 2 hours or standing for 24 hours and taking the temperature at which the substance is completely transparent). Refractive index at 60° , 1.449 to 1.451. Acid value, not more than 2.0. Saponification value, 192 to 195. Iodine value, 33 to 46. Sevum Præparatum, *U.S.P. XII*, melts at 45° to 50° ; congealing point, 37° to 40° ; saponification value, 193 to 200; iodine value, 33 to 48; the acid value of 10 g. is equivalent to not more than 6 ml. of N/10 NaOH.

ADRENALINA

Adrenalina (B.P.). $C_9H_{13}O_3N=183.1$. M.p., 205° to 212° with decomposition (the rate of rise of temperature being 10° per minute); specific rotation of a 4% w/v solution in normal hydrochloric acid, -50° to -53° . Epinephrina, *U.S.P. XII*, has an $\alpha_{D_{25}}$, determined on a 5% w/v solution of the substance, dried over sulphuric acid, in N/2 hydrochloric acid, of -50° to -53.5° . Liquor Epinephrinæ Hydrochloridi, *U.S.P. XII*, has a potency equivalent to a 0.1% solution of Reference Standard Epinephrine. Assayed biologically by measuring the rise in the systolic blood pressure of the dog and comparing it with that obtained with a standard solution.

Suprarenalum (N.F. VII) yields not less than 0.8% of natural epinephrine of glandular origin; moisture not more than 6%; ash, not more than 7%. Assayed by the method for Liquor Epinephrinæ Hydrochloridi, *U.S.P. XII*, using an extract of 0.5 g. in 50 ml. of N/10 hydrochloric acid.

Biological Methods of Determination.

Biological methods for the estimation of adrenaline are not required in any of the pharmacopœias since adrenaline is a chemical substance with well-defined chemical properties. Nevertheless biological tests are often applied to adrenaline to determine whether a particular sample is entirely pure or whether its activity corresponds, for example, to only 90% of that of the pure substance. The estimation of adrenaline on the blood pressure of the spinal cat is sufficiently accurate to detect differences of 5 or 6%.

(a) *Estimation of the blood pressure.* A cat is anaesthetised with chloroform and the spinal cord is exposed by removing the laminae of the second cervical vertebra. The spinal cord is divided and the brain is destroyed by passing a probe through the foramen magnum. The anaesthetic can then be discontinued, though the circulation is only maintained so long as artificial respiration is given. The blood pressure is recorded by placing a cannula in the carotid artery, and a cannula is placed in the jugular vein to give injections. In the cat so prepared the blood pressure is low and steady, and well suited for comparing the pressor (blood pressure raising) effect of different doses of adrenaline. A sample of pure adrenaline is taken as standard and a solution of strength 1 in 40,000 in saline acidified with hydrochloric acid is prepared. A similar solution of the unknown sample is prepared. Doses of 0.3 or 0.4 ml. are then injected, using the standard and the unknown alternately, in order to discover what amount of the unknown produces the same effect as a given amount of the standard.

(b) *Estimation on the isolated intestine.* A strip of the intestine of the rabbit is suspended in Ringer's solution; one end is fixed and the other is attached by a thread to a lever so that the movements of the strip are recorded by the lever on a smoked drum. In Ringer's solution supplied with oxygen and maintained at 37°, the strip alternately contracts and relaxes. If adrenaline is added to the bath the contractions are lessened or abolished according to the dose; when the adrenaline is removed the contractions begin again. An unknown solution of adrenaline can be compared with a known solution by using this property of inhibiting the movements.

Ewin's Colorimetric Test. Potassium persulphate is added to produce a concentration of 0.1% and the mixture placed in a boiling water-bath. A red colour is produced. This shows adrenaline in a dilution of 1 in 5 million.—H. Dryerre, *Chem. & Drugg.*, i/1922, 418.

Colorimetric determination in extracts of suprarenal glands gives results comparable with the biological test. Gland extracts at pH 5.4 and containing 0.01 to 0.1 mg. of adrenaline are mixed with an equal volume of the reagent containing potassium persulphate, 0.2%; sodium chloride, 1%; sodium phosphate, 0.239%; and sodium acid phosphate, 0.937%. The increase in red colour, determined with a tintometer, during 30 minutes at 22° is proportional to the adrenaline content.—J. H. Barker, C. J. Eastland and N. Evers, *Biochem. J.*, 1932, 2129.

Errors in the above test are due to the presence of ascorbic acid and uric acid, chiefly the former. Good agreement is found between the figure found by the pressor assay and that obtained by the colorimetric method if allowance is made for the ascorbic acid, determined by indophenol titration, and uric acid determined by the Folin method after precipitation with silver lactate and re-dissolving in lithium chloride, sodium cyanide and water.—J. Devine, *Biochem. J.*, 1937, 545.

Mercuric salts with adrenaline give a definite colour reaction which has been used for analysis of adrenaline contained in medicinal preparations. Details are given for the determination of adrenaline in adrenal extracts for injection, powdered gland, fresh gland and solution of adrenaline (1 in 1000), *Fr. Cx.* The results obtained compare closely with those given by physiological assays.—P. Bouvet, *J. Pharm. Chim., Paris*, 1939, 29, 481.

Extract of Suprarenal Cortex.

Biological Method of Assay. The potency of extracts of suprarenal cortex was first demonstrated by showing that they were able to prolong the life of cats or dogs from which the suprarenal glands were removed. This method is still used, but it suffers from the drawback that several animals are needed for testing each extract, and after the animals have been kept for 3 weeks from the time of removal of the glands it is uncertain whether some small portion of gland has regenerated or not. Very commonly rats are used, since, provided they are young,

they die after removal of the suprarenals. Schultzer has described a method (*J. Physiol.*, 1936, 87, 222) in which two preparations can be compared by injecting them daily for 21 days into groups of adrenalectomised rats. The percentage of rats which survive to the end of this period depends on the dose injected, and it is possible to discover what dose of each preparation will prolong the life of 50 per cent. of rats for 21 days. The doses of the two preparations which have this effect can then be equated.

The most rapid and the best method from the point of view of accuracy of estimating extract of suprarenal cortex is that described by Bülbring, *J. Physiol.*, 1937, 89, 64. The suprarenal glands are removed from groups of drakes. The mean survival time of uninjected birds is about 8 hours. If, however, after the operation birds are injected hourly with cortical extract, the survival time can be prolonged indefinitely. Bülbring has shown that the relation between the logarithm of the dose injected and the survival time is linear, and has determined the equation to the regression line. If a comparison of two preparations is made using 10 birds for each, the standard deviation of the comparison is 22 per cent. Since Bülbring recommends that the injections be made for a period of 20 hours, the test may be completed in one day. The operations, however, require considerable skill.

A rapid method of assay for suprarenal cortical extract is described. It is based on the increase in potassium excretion after subcutaneous injection of the extract in rats maintained on a diet of constant potassium content. For routine use four groups of four rats are used, two of these groups being injected with one dose of one extract and two with one dose of the other. The potencies can then be calculated, using the formula for the regression line, and the whole can be completed within ten days.—G. B. West, *Quart. J. Pharm.*, 1941, 26.

A method of assay for the adrenal cortical hormone based on the use of the month-old adrenalectomised rat, and a method of preparation of concentrates. The final biologically active fraction, which is practically free from N, will maintain adrenalectomised rats in daily doses of 0.1 mg., equivalent to 10 g. of whole ox adrenal gland.—G. Hunter and M. M. Cantor, *Canad. med. Ass. J.*, ii/1937, 368.

Fr. Cx. 1937. Assay of Poudre de Glande Surrénale. Shake 1 g. with 10 ml. N/10 sulphuric acid for 15 minutes and dilute to 100 ml.; to 1 g. sodium acetate in 8 ml. water add 2 ml. of the solution followed by 3 drops of mercuric chloride (5%) solution; after 3 minutes match the red coloration against a standard solution. The powder should contain at least 1% of adrenaline by the colorimetric method and by biological test.

Desoxycorticosteroni Acetas (*B.P.C. Supp. III*). $C_{23}H_{33}O_4$ = 372.25. M.p., 154° to 159° . α_D of 1% solution in dehydrated alcohol, $+175^\circ$ to $+185^\circ$. Loss at 100° , not more than 0.5%. Ash, not more than 0.1%.

ÆTHER

Æther (*B.P. Add. I*). $(C_2H_5)_2O$ = 74.08. The boiling-range should be 34° to 36° and the specific gravity should be from 0.720 to 0.724. It should comply with limit tests for peroxides and residue on evaporation. Water heated with it should have a pH value of not less than 4.9. Complies with the test for methyl alcohol in Æther Anæstheticus. Æther, *U.S.P. XII*, containing 96 to 98% of $(C_2H_5)_2O$, boils at about 35° and has a sp. gr. of 0.713 to 0.716 at 25° . Tests for acidity, residue, foreign odour on evaporation, aldehyde and peroxide are specified. Æthylis Oxidum, *U.S.P. XII*, a solvent ether containing 96 to 98% of $(C_2H_5)_2O$, conforms to less stringent tests for peroxide and aldehydes.

A British Standard Specification (B.S.S. No. 579—1934) has been issued by the British Standards Institution for Technical Ether. The specification includes requirements regarding description, sp. gr. (not exceeding 0.725 at 15.5°C), distillation, residue on evaporation, acidity, peroxides (titanium oxide test), sulphur compounds and sampling, and the appendices describe the methods and apparatus to be used.

A method, accurate to $\pm 1\%$, is described for the determination of diethylether in preparations such as simple collodion, ethereal tincture of lobelia and spirit of ether.—E. J. Boorman, *J. Soc. chem. Ind., Lond.*, 1938, 65.

An official method for the determination of ether, inapplicable in the presence of essential oils, is described in *Methods of Analysis (A.O.A.C., 1940, 604)*.

Acetone in Ether. A sample of ordinary 0.720 ether from S.V.M. gave nearly 24 parts of acetone per 10,000. As a qualitative test **Rothera's Nitro-Prusside Test** may be used. 5 ml. of ether, 1 ml. of 5% sodium nitro-prusside solution and 3 ml. of strong ammonia are shaken together. Then solid ammonium chloride is added, *q.s.* to supersaturate, and the whole shaken. Samples will show a slight reaction or none at all.—A. J. Jones, *Yearb. Pharm.*, 1919, 403.

Scott Wilson's Reagent. Dissolve mercuric cyanide, 0.5 g., and sodium hydroxide, 9 g., in water, 60 ml., and add with constant stirring 20 ml. of 0.727% silver nitrate solution. No turbidity should develop on shaking the ether with excess of the reagent.

For quantitative determination employ Scott Wilson's method.—*J. Physiol.*, 1907, 444.

Æther Anæstheticus (B.P.). The boiling-range is limited to 34° to 35°. No foreign odour is perceptible on evaporation; no brown or red colour of peroxides is produced when shaken with potassium iodide and starch solution in a completely filled bottle and set aside in the dark for half an hour; presence of acetone and aldehyde is eliminated by no colour or turbidity being produced when shaken and set aside with Nessler's reagent; and no reaction for methanol is given by water shaken with it. *Æther, U.S.P. XII*, is only to be used for anæsthesia when preserved in small well-closed containers and the original container must not have been opened more than 24 hours.

The difference between *Æther* and *Æther Anæstheticus* is the difference between two fractions from the same distillation. Anæsthetic ether is prepared from a fraction containing less than 0.5% of alcohol. Ether is prepared from fractions containing more than 0.5% of alcohol, a denaturant, usually 5% of wood spirit, being added. Only anæsthetic ether should be official.—W. H. Linnell, *Pharm. J.*, i/1933, 106.

Peroxides in Anæsthetic Ether. Decomposition, with formation of peroxides, prevented by addition of $\frac{1}{2}$ grain of hydroquinone to 4 oz. of ether. One part of hydroquinone to 5000 parts of ether is sufficient.—H. O. Nolan, *Lancet*, ii/1933, 129.

Powdered iron, 1 g. per 100 ml. of freshly distilled ether, prevents formation of peroxides.—*Pharm. J.*, ii/1927, 434.

JORRISON'S REAGENT (0.4 g. of vanadic acid in 4 ml. of sulphuric acid and 96 ml. water) gives a red colour with ether if peroxides are present. Aldehydes and unsaturated alcohols give a blue colour on keeping.—*J. chem. Soc. Abstr.*, ii/1924, 706.

Ferrous Thiocyanate Test. To ether, 5 ml., add N/10 potassium thiocyanate solution, 1 ml., and fresh 5% ferrous ammonium sulphate solution, 1 drop. If peroxide be present a pink or red tinge develops almost immediately.—F. H. Hocking, per *Chem. & Drugg.*, i/1927, 592. See also *Yearb. Pharm.*, 1924, 615.

Determination of minute quantities of peroxides. The following method is stated to be accurate for less than one part per million of ethyl peroxide. Place 10 ml. of the sample and 20 ml. of dehydrated alcohol in a 250 ml. stoppered flask, and add a freshly prepared solution of cadmium iodide, 1 g., and potassium iodide, 1 g., in 5 ml. of acetic acid (36%). Mix thoroughly and allow to stand

for one hour in the dark. Conduct a blank experiment on the reagents simultaneously. If any yellow tint is visible, titrate with N/50 sodium thiosulphate (prepared with CO_2 -free distilled water). Towards the end of the titrations stopper the flasks and shake vigorously. Each ml. of N/50 sodium thiosulphate is equivalent to 9.008 parts of $(\text{C}_2\text{H}_5)_2\text{O}_2$ per million.—L. W. Green and R. E. Schoetzow, *J. Amer. pharm. Ass.*, 1933, 412.

Æthylenum (B.P.). $\text{C}_2\text{H}_4 = 28.03$. Not more than 2% by volume of gas remains when a volume equivalent to 1000 to 1500 ml. is passed into a gas pipette containing fuming sulphuric acid or bromine solution and the residual gas treated with potassium hydroxide solution, corresponding to not less than 98% by volume of C_2H_4 ; absence of carbon monoxide in the gas remaining is shown by no further contraction of volume occurring, after treating first with alkaline solution of pyrogallol, when it is treated with freshly prepared acid cuprous chloride solution. Tests for limit of carbon dioxide, acid and sulphur dioxide, acetylene, phosphine, aldehydes and hydrogen sulphide and carbon monoxide are included. *Æthylenum, U.S.P. XII*, leaves not more than 1% by volume unabsorbed by bromine solution and potassium hydroxide solution, corresponding to 99% v/v of C_2H_4 ; 2000 ml. does not turn 100 ml. of boiled and cooled water, with methyl red and 0.2 ml. of N/100 hydrochloric acid, more red than 100 ml. of the water and methyl red with 0.4 ml. of N/100 hydrochloric acid, nor more yellow than 100 ml. of the water with methyl red. A test for limit of carbon dioxide is included. Tested for limit of carbon monoxide by addition of 2.5 ml. of diluted blood to 250 ml. of ethylene and agitation for 15 minutes; after addition of 0.02 g. each of pyrogallol and tannic acid, shaking and standing in the dark for 15 minutes, no pink colour should be observed and the grey colour produced must match that produced by similarly treating 250 ml. of air which has been collected remote from sources of carbon monoxide.

Cyclopropanum (U.S.P. XII). $\text{C}_3\text{H}_6 = 42.05$. Contains 99% v/v of C_3H_6 , by measurement of the residual gas after absorption in sulphuric acid. Limits for acids and alkalis, carbon dioxide, propylene, allene, and other unsaturated hydrocarbons and of halogens are included.

ÆTHYLIS CHLORIDUM

Æthylis Chloridum (B.P.). $\text{C}_2\text{H}_5\text{Cl} = 64.50$. Contains not less than the equivalent of 99.5% w/w of $\text{C}_2\text{H}_5\text{Cl}$. The assay by digestion with N/2 alcoholic potassium hydroxide in a water-bath for thirty minutes is incomplete; it is best conducted by introducing about 1.5 g. into a stoppered bottle containing 50 ml. of N/1 alcoholic potassium hydroxide, weighed accurately, and heating in a water-bath for at least 1 hour; titrate the excess of alkali with N/2 hydrochloric acid to phenolphthalein; conduct a blank experiment for an identical time using a bottle of exactly similar glass. During evaporation no foreign odour is at any time detectable and the residue is not more than 0.01%. Tests for

limit of acidity, alkalinity, ionisable chlorides and ethyl alcohol are included. *Æthylis Chloridum, U.S.P. XII*, is not assayed; tests for chloride, neutrality, alcohol, foreign volatile matter and residue on evaporation are included.

AGAR

Agar (*B.P.*). Yields not more than 5% of ash. It should be soluble when boiled with 100 parts of water, yielding a stiff jelly on cooling. Should yield no precipitate on addition of tannic acid to a hot 0.2% solution. 10 ml. of a rapidly cooled 0.2% aqueous solution gives a pale yellow colour with one drop of N/10 iodine and a dark purple coloration with 0.5 ml.; on setting aside for two hours, 0.5 ml. of the iodine solution gives a brownish colour. The *U.S.P. XII* substance contains not more than 1% of foreign organic matter; acid-insoluble ash, not more than 1%; moisture limit, 20% when determined by the toluene distillation method. A solution of 0.1 g. in 100 ml. of boiling water, on cooling, gives no blue colour with iodine. A 1% solution in boiling water, cooled to 50°, gives no turbidity within 10 minutes with an equal volume of picric acid solution.

Tests for Identity. The following tests for the identity of agar are recommended by the Sub-Committee on Crude Drugs of the Committee on Pharmacy and Pharmacognosy:—To 4 ml. of a 0.5% *w/v* solution in water, add 0.5 ml. of hydrochloric acid and heat for thirty minutes in a water-bath. Divide the liquid into two parts. To one part add 1.5 ml. of solution of sodium hydroxide and 3 ml. of solution of potassio-cupric tartrate and warm in a water-bath; a red precipitate is produced. To the remainder of the liquid add solution of barium chloride; a white precipitate is produced (distinction from tragacanth). When powdered it acquires a pink colour in solution of ruthenium red (distinction from acacia and tragacanth). On addition of N/50 iodine it acquires a deep crimson colour (distinction from acacia and from tragacanth).—(*British Pharmacopœia Commission Report*, No. 13, September 1939).

ALCOHOL ÆTHYLICUM

Alcohol (*B.P.*). Contains from 94.7 to 95.2% *v/v* or 92.0 to 92.7% *w/v* of C_2H_5OH . Sp. gr., 0.815 to 0.817. Refractive index at 20°, 1.3637 to 1.3639. Limit tests for acidity, alkalinity, oily or resinous substances, fusel oil and allied impurities, and aldehyde are included. Absence of methyl alcohol is shown by the *B.P.* test: 5 ml. of a 10% aqueous dilution is mixed with 2 ml. of a solution of potassium permanganate in phosphoric acid and set aside for 10 minutes, after which 2 ml. of solution of oxalic and sulphuric acids is added and to the colourless solution 5 ml. of decolorised magenta solution is added; no colour is produced within 10 minutes. Industrial methylated spirit gives a deep violet coloration within 5 minutes by this test. Residue on evaporation and drying at 100°, not more than 0.01%

w/v. The official alcohol of the *U.S.P. XII* contains not less than 92.3% *w/w* or 94.9% *v/v* of C_2H_5OH at 15.56°; residue on evaporation on a water-bath and drying at 100°, not more than 0.0025%. Tests for acidity, fusel oil constituents, amyl alcohol or non-volatile carbonisable substances, aldehydes and organic impurities, methanol and acetone, ketones, tertiary butyl alcohol and isopropyl alcohol, alkaloids and for formaldehyde are also included.

Alcohol Dehydratum (B.P.). $C_2H_5OH=46.05$. Has a sp. gr. of 0.7936 to 0.7967, a refractive index at 20° of 1.3614 to 1.3618 and contains not less than 99.4% by volume or 99% by weight of C_2H_5O . Alcohol Dehydratum, *U.S.P. XII*, containing 99% by weight of C_2H_5OH , has sp. gr. not higher than 0.798 at 15.56°.

A British Standard Specification (B.S.S. No. 507—1933) has been issued by the British Standards Institution for ethyl alcohol. The specification includes requirements regarding description, strength, miscibility with water, residue on evaporation, acidity, aldehyde content and sampling, and the appendices describe the methods and apparatus to be used. This alcohol is 66° O.P. (91.95% by weight or 94.68% by volume) or from 61° to 68° O.P. (91.83 to 95.81% by volume) if agreed between purchaser and vendor.

The strength of alcohol is usually expressed in terms of vol. %, though the Board of Customs and Excise favour "proof" terms (see Vol. I, p. 156).

Determination in Aqueous Dilutions by Capillary Rise. A method is described which is based on the variation of surface tension and density as observed by the capillary rise measurement. The sensitivity of the method is greatest when the percentage of alcohol is between 0 and 5, and if the proportion of alcohol is greater than 15% it should be diluted. The average error is then not greater than 0.05%.—F. Todd, *Amer. J. Pharm.*, 1936, 488.

Identification in Mixtures. The liquid is distilled and the distillate treated successively with a strong oxidising agent such as potassium hypochlorite in alkaline solution, and then ammoniacal silver nitrate solution and finally redistilled first in alkaline and secondly in acid solution; by this process the ethyl alcohol and its higher homologues are obtained free from other organic substances. The distillate is then oxidised quantitatively with potassium dichromate and the acid formed isolated, measured and identified. If the acid found after oxidation is identified as acetic acid, and if the amount of oxygen required, measured by the amount of potassium dichromate used, is the same as that which would theoretically be required to produce the same amount of acetic acid from ethyl alcohol, the liquid can only be ethyl alcohol. The identification of propionic, butyric or valeric acid indicates the presence of the corresponding alcohol. Butyl alcohol on oxidation yields both acetic and butyric acids, in the proportion of six parts of butyric acid to two parts of acetic acid, and thus the presence of acetic acid in the oxidation mixture does not specifically show the presence of ethyl alcohol. In a mixture of ethyl and butyl alcohols, by determining the respective quantities of the two acids formed on oxidation and subtracting the proportion of acetic acid produced from the butyl alcohol, the quantity of acetic acid produced from the ethyl alcohol is obtained, and the original amount of ethyl alcohol may be calculated.—M. Nichoux, *C. R. Acad. Sci., Paris*, 1936, 203, 16.

ALCOHOL DILUTION RULES

If *V* be the volume percentage of the stronger alcohol and *v* that of the alcohol required—

I. *By volume.* Mix *v* volumes of the stronger alcohol with distilled water, q.s., after cooling to make *V* volumes, e.g. to make an alcohol 43% from alcohol 95% take 43 volumes of the 95% and make up to 95 volumes. (See also Appendix III, *B.P.C.* '34, for temperature correction tables.)

II. *By weight.* Proceed on the same lines by weight throughout.

To Transpose Volume per cent. of Alcohol into Weight per cent.
The volume per cent. is multiplied by 0.7938, and the product divided by the sp. gr. of the liquid, e.g., 80.22% v/v = $\frac{80.22 \times 0.7938}{0.863} = 73.7875\%$ w/w.

To express the weight per cent. as volume per cent. divide the weight per cent. by 0.7938 and multiply by the sp. gr. of the liquid, e.g., 90.29% by weight = $\frac{90.29 \times 0.822}{0.7938} = 93.49\%$ v/v.

Proof Spirit Conversion Factors (F. C. J. Bird, *Chem. & Drugg.*, Dec. 27 1919).

METRIC MEASURE.

To express:—

| | | | | | |
|-----------|-----|-------------------------------|----|-------------|--------|
| Litres of | 90% | Alcohol B.P. in PROOF GALLONS | .. | Multiply by | 0.3471 |
| " | 70% | " | " | " | 0.2697 |
| " | 60% | " | " | " | 0.2312 |
| " | 45% | " | " | " | 0.1733 |
| " | 20% | " | " | " | 0.0767 |

IMPERIAL MEASURE.

| | | | | | |
|---------|-----|-------------------------------|----|-------------|--------|
| Gallons | 90% | Alcohol B.P. in PROOF GALLONS | .. | Multiply by | 1.5779 |
| " | 70% | " | " | " | 1.2263 |
| " | 60% | " | " | " | 1.051 |

| " | 20% | " | " | " | 0.3487 |

QUANTITY OF SPIRITS WHICH MAY BE SOLD BY A CHEMIST WITHOUT LICENCE.

In view of the Immature Spirits (Restrictions) Act, 1915, the Commissioners of Customs and Excise reduced the quantity of duty-paid Spirits of Wine (including Absolute Alcohol), which may be sold without a licence, to 5 ounces fluid. Strict inquiries should be made by the pharmacist as to requirements. —*Pharm. J.*, i/1922, 505.

To State Volume per cent. as Alcohol of Proof Strength. Multiply V per cent. by 1.753 and deduct 100 from the product. Thus 65% v/v = $65 \times 1.753 - 100 = +13.945^\circ$ over proof. Further, alcohol of 25% v/v = $25 \times 1.753 - 100 = -56.175^\circ$ proof, i.e., 56.175° under proof.

(B.P. 1885 stated: Proof spirit=about 57% C_2H_5OH by vol., i.e., 57 parts alcohol with water produce 100 parts proof spirit.)

∴ 1 part pure alcohol = $\frac{100}{57} = 1.753$ (about) parts proof strength.

Conversely, to State Alcohol of Proof Strength as Volume per cent.:—

Add 100 to the proof strength and divide the product by 1.753; thus,

$$13.945^\circ \text{ o.p.} = \frac{113.945}{1.753} = 65\% \text{ by vol., and}$$

$$56.175^\circ \text{ u.p.} = \frac{100 - 56.175}{1.753} = 25\% \text{ by vol.}$$

To Convert Bulk Gallons to Proof Gallons multiply by

$$\frac{\text{Proof Strength} + 100}{100}$$

100 vols. of alcohol 90% (approx. 58° o.p.) are equivalent to 153 vols. of proof spirit.

"Proof Spirit" has sp. gr. 0.920. This, formerly, was found to be the weakest spirit that could be put to the proof of igniting a little gunpowder moistened with it. If the spirit caught fire and inflamed the gunpowder, it was designated "over proof," and if not, "under proof." By the Hydrometer Act, 58 Geo. III., cap. 28, Proof Spirit is defined as spirit of strength which, at a temperature of 51°F., weighs exactly twelve-thirteenths of an equal quantity of distilled water.

The following Table, founded on B.P. 1898 and Gilpin's Tables, shows:—

(i) The volume of distilled water necessary to be added to 100 volumes of alcohol (90%) for the production of each strength of diluted alcohol.

(ii) The volumes of alcohol (90%), and of distilled water respectively which, when mixed and reduced to 60°F. (15.5°C.), will produce, allowing for contraction in volume, 1000 ml., 1 pint, or 1 gallon of each strength of diluted alcohol.

The sp. gr. and the exact Excise (Sikes') strength at 60°F. (15.5°C.), in degrees over proof (O.P.) and under proof (U.P.), of each dilution, are given in the first column.

Table for the Dilution of Alcohol (90%) to Weaker Strengths

| Volume Percentage, Specific Gravity, and Excise Strength | Alcohol (90%) | Distilled Water | Volume Produced |
|--|--|--------------------|--|
| 70 % Sp. gr. 0.8900 22.7 O.P.† | 100 vols. + 31.05 vols. 777.8 ml. + 241.6 ml. *648.5 g. + 241.6 g. 15 oz. 266 m. + 4 oz. 398 m. 124 oz. 215 m. + 38 oz. 307 m. *6 lbs. 7½ oz. + 2 lbs. 6½ oz. | | = 128.57 vols. = 1000 ml. = 1000 ml. = 1 pint = 1 gal. = 8 lbs. 14½ oz. |

Analysis of Wines. *P. Helv. V* gives a useful summary.

Spirit tables for use with Sikes' A and B Hydrometers, issued by the Commissioners of H.M. Customs and Excise for use in connection with "The Strength and Weight of Spirits Ascertainment Regulations," are available (H.M. Stationery Office).

Alcohol Limits of B.P. Galenicals. Insufficient allowance has been made for moisture in the air-dry drug and for the volume occupied by the solid extractive. Revised limits are suggested for the majority of preparations.—T. T. Cocking, *Quart. J. Pharm.*, 1934, 76.

Presence of Methyl Alcohol in Galenicals. Some official preparations, especially those prepared from orange or lemon peel, contain methyl alcohol, probably derived from decomposition of pectin. The quantity present is sufficient to respond to Denigés' test.—R. W. Richardson, *Pharm. J.*, ii/1936, 249.

Diethyl Phthalate. A British Standard Specification (B.S.S. No. 574—1934) has been issued by the British Standards Institution for diethyl phthalate. The specification includes requirements regarding description, specific gravity (1.114 to 1.129 at 15.5°), refractive index (1.4805 to 1.506 at 20°), water, ash, acidity, ester content (not less than 98% w/w) and sampling, and the appendices describe the methods and apparatus to be used.

DETECTION OF DIETHYL PHTHALATE IN ALCOHOLIC LIQUIDS. The following test of the Bureau of Internal Revenue of the U.S. Treasury Department was found satisfactory:—(a) In presence of considerable amount. To 10 ml. of sample add 2 ml. of 10% NaOH and evaporate to dryness on the steam-bath. Add 5 ml. of conc. sulphuric acid and 0.025 g. of resorcinol and heat for 5 minutes on the steam-bath. Transfer to a test-tube, heat in oil bath at 160° for 5 minutes, cool, pour into excess of alkaline water. A greenish yellow fluorescence (due to fluorescein) is produced. (b) In presence of traces. To not less than 50 ml. add 0.2 ml. of 10% NaOH and proceed as above. Allow the dilute fluorescein solution to stand 24 hours and view through the long axis of a Nessler glass. A blank test on pure alcohol should be made for comparison since a fluorescence is produced in the absence of diethyl phthalate which fades in 24 hours.—J. A. Hardy & L. F. Hoyt, *J. Amer. pharm. Ass.*, 1925, 219.

The following methods are suggested for determination of ethyl phthalate in perfumes or in the presence of essential oils.

As dipotassium phthalate. 1 to 2 g. of sample is refluxed for 1 hour with 25 ml. of N/2 potassium hydroxide in commercial absolute alcohol in a conical flask provided with a cooling tube. The cooling tube is then rinsed with more alcohol and the contents cooled on ice, centrifuged and filtered on a sintered glass filter. The precipitate is washed with 30 to 50 ml. of ice-cold absolute alcohol, heated at 140°, and weighed. 1 g. of precipitate corresponds to 0.917 g. of ethyl phthalate. Other acids giving insoluble potassium salts must be absent. A method is also described in which the potassium salt is converted to the lead salt. A method is also given for determination as lead phthalate.—Y. R. Naves and S. Sabetay, *Bull. Soc. Chim.*, 1937, 5, 102.

Distil a mixture of 25 ml. of sample and 50 ml. of water, collecting 50 ml. of filtrate. Evaporate 10 to 12 ml. of filtrate (or sufficient to correspond to about 5 ml. of absolute alcohol) to dryness on a steam-bath with 5 to 6 drops of sodium hydroxide. When dry moisten with 5 to 6 drops of dilute sulphuric acid to dissolve the sodium salts, add 1.2 ml. of sulphuric acid, rub with a glass rod to ensure complete solution and add to 0.05 g. of resorcinol in a long narrow test-tube. Immerse the tube in an oil-bath at 165° to 175° for from 3½ to 4 minutes; then cool the tube, transfer 0.2 to 0.5 ml. of the acid solution to a 50 ml. separator, add 5 to 10 ml. of water and shake thoroughly with 8 to 10 ml. of ether for 30 seconds. Allow to separate, reject the lower layer, wash the residue three or four times with 10 ml. quantities of water until free from acid, and pour off the ether extract into a long narrow test-tube. To the ether extract add down the side of the tube 2 ml. of 5% sodium hydroxide and allow to stand for 15 minutes. If any diethyl phthalate is present a yellowish-green fluorescence will appear.—I. Schwartz, *J. Amer. pharm. Ass.*, 1936, 749.

Spiritus Frumenti (U.S.P. XII). Contains at 15.56°, 47 to 53% v/v of C₂H₅OH and must have been kept in charred wood containers for not less than 4 years. Complies with tests for glycerin, sugar, etc., indication of storage in wood barrels, acidity, esters, acetone, other ketones, isopropyl alcohol and

tertiary butyl alcohol, for methanol, alkaloids, caramel and some coal tar dyes, and for formaldehyde.

Spiritus Vini Vitis (*U.S.P. XII*). Contains at 15-56°, 48 to 54% *v/v* of C_2H_5OH , and is stored in wood barrels for at least 4 years; complies with a test for acidity and other tests given under *Spiritus Frumenti, U.S.P. XII*.

Alcohol Tribromoethylicum (*B.P. Add. III*). $CBr_3CH_2OH = 282.8$. M.p., 79° to 81°. Presence of dibromoacetaldehyde is limited by adding phenylhydrazine acetate solution to a 2% solution in water when no precipitate forms during 30 minutes; limits of readily carbonisable substances, acidity, ionised halogens sulphates, and heavy metals. Leaves on incineration not more than 0.05% of residue. Contains not less than 99% CBr_3CH_2OH ; assayed by refluxing for 2 hours with N/1 sodium hydroxide, followed by titration of the bromide with excess silver nitrate solution and ammonium thiocyanate. Assayed similarly, after drying for 18 hours over sulphuric acid, Tribromoethanol, *U.S.P. XII*, complies with the same standard for purity. M.p., 79° to 82°, loss on drying, not more than 1%, ash not more than 0.1%.

Bromethol (*B.P. Add. III*) is a 66.7% *w/v* solution of tribromoethyl alcohol in amylene hydrate. *Liquor Tribromoethanolis, U.S.P. XII*, is a solution in the same solvent containing 99 to 101% *w/v* of $C_2H_5Br_3O$.

Vinum Xericum (*B.P.C.*). Contains not less than 16% *v/v* of ethyl alcohol. Sp. gr., 0.990 to 1.000. Total acids as tartaric acid ($C_4H_6O_6$) not less than 0.4%. It contains not more than 450 parts per million of sulphur dioxide, to comply with the Public Health (Preservatives in Food) Regulations. The alcohol content is determined by Method I of the British Pharmacopœia:

Dilute 25 ml. with 100 to 150 ml. of water in a 500 to 800 millilitre flask; add a little pumice powder; connect by a still-head to a condenser and distil at least 90 ml.; dilute with water to 100 ml. at the same temperature as that at which the original volume was measured, determine the sp. gr. and refractive index and by reference to tables calculate the percentage of ethyl alcohol in the original wine; if the refractive index differs by more than 0.0002 from that corresponding with the specific gravity found, saturate 75 ml. with sodium chloride and shake for several minutes with 100 ml. of light petroleum (b.p. 50° to 60°); after standing for half an hour run off the lower layer and wash the petroleum layer with 25 ml. of brine; distil the mixed brine liquids after making just alkaline with normal sodium hydroxide to solid phenolphthalein and determine specific gravity and refractive index as before. Total acids are titrated with fifth normal sodium hydroxide to phenolphthalein.

Sulphur dioxide may be determined by boiling for 10 minutes 500 ml. of water and 20 ml. of hydrochloric acid in a round-bottomed litre flask, which is connected with a water-cooled reflux condenser of which the upper end connects with two absorption flasks in series each containing 10 ml. of hydrogen peroxide solution, and maintaining a current of carbon dioxide (passed through sodium carbonate solution) through the apparatus during the whole process; the contents of the flask are cooled and 50 to 100 grammes of the wine introduced as quickly as possible and boiled for 45 minutes; the absorption flasks are disconnected and the contents titrated with N/10 sodium hydroxide using bromophenol blue as indicator, and subtracting the amount of standard sodium hydroxide required to neutralise 20 ml. of the hydrogen peroxide solution to bromophenol blue.

ALCOHOL AMYLICUM

Alcohol Amylicum (*B.P.C.*). $C_5H_{12}O = 88.09$. Boiling-range 128° to 132° . Sp. gr., 0.815 to 0.817. Acidity as $CH_3 \cdot COOH$, not more than 0.01%.

A *B.S.S.* (No. 696, Part 2, 1936) has been prepared by the British Standards Institution for amyl alcohol for use in the Gerber test.

Iso-Amyl Butyrate. $CH_3 \cdot CH_2 \cdot CH_2 \cdot COO \cdot CH_2 \cdot CH_2 \cdot CH < \begin{smallmatrix} CH_3 \\ CH_2 \end{smallmatrix} = 158.144$. Colourless liquid with sp. gr. 0.882 at 0° . Used as a flavouring agent. Commercially the article contains 78 to 93%; sp. gr. ranges from 0.853 to 0.860. Refractive index, 1.4073 to 1.4110 at 20° . B.p. about 135° .

Amylis Nitris (*B.P.*). $C_5H_{11}O_2N = 117.1$. Contains not less than 90% *w/w* of nitrites, calculated as $C_5H_{11}O_2N$. At least 85% distils between 90° and 100° . Sp. gr., 0.874 to 0.884. Assayed by the interaction of an alcoholic dilution with potassium iodide solution and dilute sulphuric acid in a brine-charged nitrometer, and measurement of the nitric oxide produced; at 15.5° and normal pressure each millilitre of moist nitric oxide is equivalent to 0.0049 g. of $C_5H_{11}O_2N$. Amylis Nitris, *U.S.P. XII*, contains not less than 90% of $C_5H_{11}ONO$, when assayed by the general method for nitrites; carbon dioxide is passed through a solution of potassium iodide in boiling deaerated water, while cooling for three minutes, after adding a dilute hydrochloric acid (1 in 2) (any iodine liberated being just decolorised with N/10 sodium thio-sulphate) and while a dilution of the amyl nitrite in aldehyde-free alcohol is introduced into the mixture; the liberated iodine is then immediately titrated with sodium thiosulphate, all additions being made through an outlet tube to the flask employed, of specified dimensions. Amylium nitrosum, *P. Helv. V*, is assayed by decomposing the amyl nitrite by shaking for 5 minutes 0.5 g. in 10 ml. of alcohol with 20 ml. of N/10 silver nitrate, 15 ml. of saturated solution of potassium chlorate and 5 ml. of dilute nitric acid. The mixture is then filtered and 50 ml. of the filtrate is titrated with N/10 ammonium thiocyanate using iron alum as indicator. Each millilitre of N/10 silver nitrate is equivalent to 0.0351 g. of $C_5H_{11}O_2N$.

Amyleni Hydras (*B.P. Add. III*). $C_5H_{12}O = 88.09$. Sp. gr., 0.814 to 0.817. Not less than 95% by volume distils between 100° and 104° . Other amyl alcohols, amylene and other organic impurities limited by mixing 1 part in 20 parts water with 0.25 ml. potassium permanganate solution, which should not be completely decolorised in 10 minutes; it should have no reducing action on ammoniacal silver nitrate on heating at 60° for 10 minutes. No cloudiness (limit of water) should be produced when mixed with an equal volume of light petroleum (b.p., 50° to 60°). Residue on evaporation and drying at 100° , not more than 0.01% *w/v*. Amyleni Hydras, *U.S.P. XII*, boils between 97° and 103° ; sp. gr. at 25° , 0.803 to 0.807, non-volatile residue not more than 0.25%. Limit tests are included for acidity, heavy metals, aldehyde, readily oxidisable substances and water.

ALCOHOL ISOPROPYLICUM

Alcohol Isopropylicum (B.P.C.). $(\text{CH}_3)_2\text{CHOH} = 60.06$. Boils between 80.5° and 81.5° and contains about 96% v/v (equivalent to about 94% w/w) of $\text{C}_3\text{H}_8\text{O}$; sp. gr., 0.810 to 0.812. It may be detected in methyl or ethyl alcohols by the production of a white or yellow precipitate on heating the liquid to be tested just to boiling with mercuric sulphate solution. It may be separated in solutions of ethyl and methyl alcohols by saturating with salt, when an upper layer of isopropyl alcohol separates.

Table for calculating the percentages of isopropyl alcohol in mixtures of isopropyl alcohol and water from their Zeiss refractometer readings at 20° to 25° , also a table of specific gravities at $20^\circ/20^\circ$ and $25^\circ/25^\circ$ of mixtures of isopropyl alcohol and water containing from 2 to 25% of the alcohol.—J. Batscha and S. Reznick, *J. Ass. off. agric. Chem., Wash.*, 1937, 107.

Detection of isopropyl alcohol.—*Amer. J. Pharm.*, 1931, 341; *Analyst*, 1931, 115.

Determination. A definite volume equivalent to about 15 ml. of 0.1% solution is heated with 0.4 g. of powdered potassium dichromate and 3 ml. of 4% sulphuric acid solution, shaken and allowed to stand for 24 hours. The mixture is then made alkaline with potassium hydroxide, diluted to 100 ml. and distilled. 60 ml. of distillate is heated with 40 ml. of N/1 potassium hydroxide and 25 ml. of N/10 iodine. After standing for 15 minutes, the liquid is acidified with a mixture of equal parts of hydrochloric acid and water and the excess of iodine titrated with N/10 sodium thiosulphate.—H. Kemal, *Z. anal. Chem.*, 1936, 107, 33.

Determination of acetone, isopropyl alcohol and alcohol in mixtures.—*See Adams and Nicholls, Analyst*, 1929, 2.

Isopropyl alcohol made in Great Britain is obtained by catalytic reduction of acetone. In perfumery, it is a good plan to blend with ethyl alcohol, the odour of isopropyl alcohol being too heavy and persistent when used alone. A table of solubilities of oils and synthetic perfumes in various spirits is given.—*Chem. & Drugg.*, 1/1927, 11.

Normal Butyl Alcohol. A British Standard Specification (B.S.S. No. 508—1933) has been issued by the British Standards Institution for Normal Butyl Alcohol (Butanol). The specification includes requirements regarding description, specific gravity, distillation-range, flash-point, residue on evaporation, acidity, aldehyde content and sampling, and the appendices describe the methods and apparatus to be used.

Dibutyl Phthalate. A British Standard Specification (B.S.S. No. 573—1934) has been issued by the British Standards Institution for Dibutyl Phthalate (di-normal-butyl ester of ortho-phthalic acid). The specification includes requirements regarding description, specific gravity, refractive index, water, ash, acidity, ester content and sampling, and the appendices describe the methods and apparatus to be used.

ALCOHOL METHYLICUM

Alcohol Methylicum (B.P.C.). $\text{CH}_3\text{OH} = 32.03$. Sp. gr. not higher than 0.799. Limit of ethyl alcohol is included by shaking with 10 volumes of 10% sodium hydroxide solution and 5 volumes of N/10 iodine solution when no turbidity or precipitate appears and no odour of iodoform develops when heated to from 60° to 70° for half an hour. On acidifying with acetic acid a mixture of 5 ml. of the alcohol, 2 ml. of normal sodium hydroxide and 0.2 ml. of 2% sodium nitroprusside solution, no violet colour is produced within one minute, limiting the acetone present. It may be estimated in alcoholic mixtures by matching with a series of control concentrations when oxidised with potassium permanganate and

phosphoric acid, decolorising after 10 minutes with oxalic and sulphuric acids and treating with decolorised magenta solution as described under Alcohol, previously making sure that the solution contains no formaldehyde.

A tentative method for the determination of methyl alcohol (0.5 to 5%) in the presence of ethyl alcohol is described in *Methods of Analysis (A.O.A.C., 1940, 611)*.

A British Standard Specification (B.S.S. No. 506—1933) has been issued by the British Standards Institution for Methyl Alcohol (Methanol). The specification includes requirements regarding description, specific gravity, distillation range, residue on evaporation, miscibility with water, acidity, aldehydes and ketones, sulphur and sulphur compounds, and sampling, and the appendices describe the methods and apparatus to be used.

Spiritus Methylatus Industrialis (B.P.). Sp. gr. not greater than 0.817. Residue at 100° not more than 0.01%.

Spiritus Methylatus Industrialis sine Acetone (B.P.C.). Sp. gr. not greater than 0.817. An acetone limit is specified: when to 5 volumes diluted with water to 10 volumes, 1 volume of 1% *o*-nitrobenzaldehyde in 50% alcohol and 1 volume of 15% sodium hydroxide solution are added the colour developed in 15 minutes should not be deeper than that produced by similarly treating 10 volumes of 0.025% *v/v* solution of acetone in 50% alcohol.

Acetone. Colorimetric method for determining and detecting in spirit, based on formation of indigo when sodium hydroxide is added to a mixture of *o*-nitrobenzaldehyde and acetone; can also be used for isopropyl alcohol after oxidation to acetone.—C. A. Adams, *Pharm. J.*, ii/1928, 604.

ALOE

Aloe (B.P.). Loss at 100° not more than 10%. Ash not more than 5%. Aloes, in powder, complies with the standard for the unground drug. On boiling with 100 parts of water until nearly dissolved, cooling, adding 1 part of diatomite and filtering, 5 ml. of the filtrate with 2 ml. of nitric acid gives a yellow-brown colour changing quickly to vivid green in the case of Cape aloes, Curaçao aloes gives a deep brownish red, in the case of the Socotrine variety a pale brownish yellow and with Zanzibar aloes a yellowish-brown colour is produced. In the *U.S.P. XII* the Socotrine and Curaçao varieties are official. Aloe, *U.S.P. XII*, should yield not more than 4% of ash, not more than 12% of moisture, and not less than 50% of water-soluble extractive determined by maceration and washing of the residue, evaporation and drying at 110°. Alcohol-insoluble substances, not more than 10%. Aloe, *P. Helv. V*, contains less than 12% of moisture and 1.5% of ash. Curaçao and Natal aloes are excluded and the product contains not less than 80% of non-resinous substances soluble in a mixture of 5 parts of methyl alcohol and 30 parts of chloroform.

Extract Content in Aloes. Average content water-soluble in Barbados aloes was 60%, and in Socotrine aloes 45% approx.

The proportion of aloes or other emodin-containing drug in a preparation may be determined by extraction with ether in the presence of acid and measuring the red colour that is produced when the ether extract is made strongly alkaline

with ammonia. Results are given for Socotrine, Cape and Curaçao aloes.—P. Valaer and G. E. Mallory, *Amer. J. Pharm.*, 1934, 81.

Differentiation of Aloes by Quinoline Hydrogen Peroxide Reagent. 30% hydrogen peroxide is shaken with an equal volume of quinoline (synthetic). Heat is evolved. At first the quinoline forms the top layer, but, after shaking, the lower. The quinoline is separated, dried with anhydrous sodium sulphate and filtered. Or in preference proceed more dilute. Finally dilute to 1% with more quinoline. A few mg. of finely powdered aloes are moistened with the reagent and warmed to 60° for 3 to 5 minutes. *A. chinensis* and *A. vulgaris* give purple, turning rose pink on acidifying with 1% sulphuric acid; *A. Perryi* brown with hydrogen peroxide, remaining so on acidifying; *A. ferox* and *A. spicata*, and others, green with hydrogen peroxide, changing to greenish yellow on adding acid.—E. J. Schorn, *Pharm. J.*, i/1930, 212; see also A. H. Ware, *ibid.*, 596.

Aloinum (B.P. Add. I). Ash not more than 0.5%. Water-insoluble matter not more than 1.5%, by shaking frequently for 2 hours and drying at 100°. The proportion of water-insoluble matter varies greatly with the temperature of the water, and samples giving less than 1.5% at 25° may yield as much as from 7 to 10% at 15°. The B.P. Add. I specifies a temperature of 25° to be maintained throughout this test and facilitates manipulation by filtration through a tared Gooch crucible. Aloinum, *U.S.P. XII*, leaves not more than 0.6% of ash; water-insoluble matter, not more than 1.5%, at 25°. A benzene extract should not impart a pink colour to an equal volume of 5% ammonia water.

Aloin may be determined in mixtures containing cascara, rhubarb, senna and other acid hydrolysable anthra-glucosides, resins and phenolphthalein by the official method of *Methods of Analysis (A.O.A.C., 1940)*. The substance dried for 1 hour at 110° and containing about 0.3 g. of aloin, mixed with 10 ml. of water and 5% sodium hydroxide, is diluted with 60 ml. and made acid with sulphuric acid as quickly as possible, diluted to 100 ml., shaken for 1 hour and filtered. 40 ml. of the filtrate with 10 ml. of sulphuric acid (10% w/w) is refluxed in a continuous extractor charged with chloroform. The aqueous solution is then saturated with salt and extracted with chloroform-alcohol (3:1), which is afterwards washed with 1 ml. of water with 1 g. sodium bicarbonate, filtered, evaporated and dried at 110° for 1 hour. The aloin can then be acetylated, and the aloin hexa-acetate extracted with chloroform and dried at 110°. Aloin hexa-acetate $\times 0.615 = \text{aloin}$.

ALUMINIUM

Alumen (B.P. Add. I). $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O} = 474.4$ or $\text{NH}_4\text{Al}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O} = 453.3$. Contains not less than 99.5% of the appropriate pure substance. Ammonia alum leaves not more than 0.5% of residue when the filtrate from 1 g. in 100 ml. of boiling water and excess of dilute ammonia solution, is evaporated and ignited. Both alums are assayed gravimetrically by precipitation as aluminium hydroxide and ignition to Al_2O_3 . In the limit test for ammonium salts in potash alum, the limit allowed is equivalent to 0.1% of NH_3 , 0.01 g. being used for the test. Alumen, *U.S.P. XII*, is either ammonia alum or potash alum containing 99.5% of the pure alum. Limit of alkalis and alkaline earths, 0.5%.

Determination of Aluminium. Aluminium may be separated quantitatively from iron by precipitating the iron as sulphide in ammoniacal tartrate solution, and after removing the sulphides from the filtrate the aluminium is precipitated

as aluminium hydroxyquinolate by adding a 5% solution of 8-hydroxyquinoline sulphate to the ammoniacal solution. The mixture is heated to 90°, allowed to stand and the precipitate dried and weighed.—J. Haslam, *Analyst*, 1933, 270.

Aluminium can be determined by means of 8-hydroxyquinoline, *syn. oxine*, C_9H_7NOH . The slightly acid test solution containing about 0.02 g. of Al per 100 ml. is warmed to 50° to 60° and precipitated by the addition of the acetic 8-hydroxyquinoline solution in slight excess. The mineral acid is neutralised by the addition of 40 g. of ammonium acetate dissolved in water and the precipitate collected, washed with water, and dried at 110°. The residue, $Al(C_9H_6ON)_3$, contains 5.87% of Al. The precipitate may also be determined volumetrically as described for magnesium, after solution in concentrated hydrochloric acid and dilution with about 5 times the volume of water. Each millilitre of N/5 bromine is equivalent to 0.0004495 g. of Al.

The aluminium complex is obtained in the anhydrous form by drying at 98° and there is no particular advantage save that of speed in drying at higher temperatures.—R. C. Chirnside, C. F. Pritchard and H. P. Rooksby, *Analyst*, 1941, 402.

Small amounts of aluminium such as in plant ashes and fruit juices may be determined by precipitating the iron and aluminium as phosphates; the precipitate is dissolved in acid, the iron removed with cupferron and the aluminium precipitated with 8-hydroxyquinoline. Full practical details of the process are included.—L. Hart, *J. Ass. off. agric. Chem., Wash.*, 1932, 285.

Detection of Aluminium. Small amounts of aluminium can be detected and determined by means of Ammonium Aurine-tricarboxylate. *Syn. Aluminon*. $(C_6H_5-OH-COONH_4)_3$; C : $C_6H_5(COONH_4)$: O. The reagent is used as a 0.1% solution in water. To the solution to be tested, evaporated to about 5 ml. and acidified slightly with hydrochloric acid, is added 5 ml. of 25% w/v ammonium acetate solution and an equal volume of the reagent solution. In the presence of aluminium a red coloration or precipitate is produced on allowing to stand for 5 minutes. The colour is reduced in intensity if ammonium carbonate solution be added, but the similar lake formed by chromium is decomposed and interference from Cr ions thereby eliminated. The solution to be tested must be free from iron, and excess of alkaline earth metals must be avoided. The test may also be used quantitatively.

Alumen Exsiccatum (B.P.C.). $KAl(SO_4)_2 = 258.2$. Potash alum deprived of its water of crystallisation. Determined gravimetrically it contains not less than 99.5% of $KAl(SO_4)_2$, calculated on the dried substance. Loses at 200° not more than 10% of its weight. Alumen Exsiccatum of the *U.S.P. XII* may be either potash alum or ammonia alum heated at a temperature not exceeding 200° until aqueous vapours cease to be evolved. After drying at 200°, it contains not less than 96.5% of $AlNH_4(SO_4)_2$ or $AlK(SO_4)_2$. Assayed, after filtering out any matter insoluble in water, by precipitation as hydroxide and ignition to oxide. Yields not more than 2.5% of water-insoluble matter, dried at 100°; loss at 200°, not more than 10%.

Aluminii Sulphas (B.P.C.). $Al_2(SO_4)_3 \cdot 16H_2O = 630.4$. Assayed as for Alumen, it yields Al_2O_3 equivalent to not less than 99% of $Al_2(SO_4)_3 \cdot 16H_2O$. The substance of the *N.F. VII* is $Al_2(SO_4)_3 \cdot 18H_2O$, of which it should contain not less than 99.5% corresponding to a yield of 15.22% of aluminium oxide in the assay. Sulfate d'Aluminium, *Fr. Cx.* 1937, yields on incineration not less than 13% of Al_2O_3 .

Diatomite (B.P.C.). Purified kieselguhr from diatomaceous or infusorial earth. Moisture limit (on ignition), 10%. Ignited acid-soluble residue, not more than 1%. Terra Silicea Purificata, *U.S.P. XII*, is required to comply with the same limit for moisture and leaves an acid-soluble residue of 1.6%.

Kaolinum Ponderosum (*B.P. Add. VI*). Loss on ignition at a red heat, not more than 15%. Residue after ignition of the acid-soluble matter, not more than 1%. Kaolinum, *N.F. VII*, leaves not less than 85% of non-volatile residue on ignition. Ignited acid-soluble residue, not more than 2%.

Kaolinum Leve (*B.P. Add. VI*). Complies with the purity tests described under heavy kaolin, with a limit test for coarse particles, and limits for particles larger than 10μ diameter and for particles larger than 3μ diameter determined by taking the specific gravity of suspensions under stated conditions.

Talcum Purificatum (*B.P.C. Supp. IV*). Loss on ignition at red heat, not more than 2.5%. Water-soluble residue, not more than 0.2%. Ignited acid-soluble residue, not more than 0.5%. The *U.S.P. XII* substance is allowed 5% loss on ignition. Talc, *Fr. Cx.* 1937, has a density of 2.5 to 2.8.

Bentonitum (*U.S.P. XII*). Complies with a test for fineness of powder and loses 5 to 8% at 110° .

Sodium Silicate, Solution of. *Syn.* Soluble Glass, Water Glass. A viscid solution usually containing 10% of caustic soda and 20% of silica. *Liquor Natrii silicici, P.G. VI*, has a sp. gr. of 1.296 to 1.396. The solution will arrest the putrefaction of organic matter. In powder form, this silicate is used medicinally in France, but both it and silica would appear to be unsuitable chemicals for use *per os*.

Potassium Silicate, Solution of. *Syn.* Soluble Glass. This was the original preparation. It is less viscid than the sodium compound and is also used to impregnate bandages for treating fractures.

AMMONIUM

Ammonii Carbonas (*B.P.*). A variable mixture of bicarbonate ($\text{NH}_4\text{HCO}_3 = 79.05$) and carbamate ($\text{NH}_4\text{NH}_2\text{CO}_2 = 78.06$) Determined by dissolving in excess standard acid, boiling, cooling and back titrating with standard alkali using methyl red as indicator, it contains the equivalent of from 30 to 32.5% of NH_3 . Residue on volatilisation, not more than 0.025%. *Ammonii Carbonas, U.S.P. XII*, yields from 30 to 33% of NH_3 ; the titration is conducted without boiling and methyl orange is used as indicator. Ash, not more than 0.05%; the limit of sulphate allowed is two-fifths that of the *B.P.* substance, and a test for thiosulphate is included. Carbonate d'Ammonium, *Fr. Cx.* 1937, titrated to helianthin indicator, contains not less than 30% of NH_3 . Ammonium carbonicum, *P.G. VI*, consists of ammonium bicarbonate or a mixture of ammonium carbonate and ammonium bicarbonate containing from about 21 to 33% of NH_3 .

Liquor Ammonii Carbonatis (*B.P.C. Supp. II*). Determined as for *Ammonii Carbonas*, it contains the equivalent of 1.9 to 4.7% *w/v* of NH_3 .

Stability of Aqueous Solution. A 1 in 8 solution was found to be stable. —Corfield and Self, *Pharm. J.*, i/1926, 132.

Ammonii Bicarbonas (*B.P.*). $\text{NH}_4\text{HCO}_3 = 79.05$. Contains from 98% to the equivalent of 102% of NH_4HCO_3 , by adding

excess of acid, boiling, cooling and back titrating to methyl red. Residue on volatilisation, not more than 0.01%.

Liquor Ammoniaë Aromaticus (B.P. Add. V). Contains ammonia and ammonium carbonate equivalent to 2.1 to 2.4% *w/v* of NH_3 and 1.265 to 1.485% *w/v* of CO_2 . Determined by the assay described for Spiritus Ammoniaë Aromaticus.

Liquor Ammoniaë Fortis (B.P.). Has a specific gravity of 0.885 to 0.891 and contains not less than 31.5% and not more than 33.5% by weight of NH_3 . Methyl red is used as indicator for titration in excess normal sulphuric acid with normal sodium hydroxide. Residue on evaporation on a water-bath, not more than 0.01% *w/v*. Liquor Ammoniaë Fortis, *U.S.P. XII*, contains from 27 to 29% of NH_3 by weight. Assayed by direct titration after dilution with water with normal sulphuric acid to methyl red. Sp. gr., about 0.897 at 25°. Residue on evaporation and drying at 120°, not more than 0.06%. Ammoniaque Officinale, *Fr. Cx.* 1937, contains 20.18% NH_3 .

Liquor Ammoniaë Dilutus (B.P.). An aqueous solution containing not less than 9.5% and not more than 10.5% *w/w* of NH_3 . Residue on evaporation on a water-bath, not more than 0.005% *w/v*. Sp. gr., 0.958 to 0.9615. Liquor Ammoniaë Dilutus, *U.S.P. XII*, contains from 9 to 10% *w/v* of NH_3 , with sp. gr. about 0.957 at 25°. Residue on evaporation and drying at 120° not more than 0.02%. The dilute solution of the *Fr. Cx.* 1937 contains 10.09% NH_3 .

Spiritus Ammoniaë Aromaticus (B.P.). Contains ammonia and ammonium carbonate equivalent to 2.1 to 2.4% *w/v* of NH_3 , and 1.265 to 1.485% *w/v* of CO_2 . Total ammonia determined by addition of excess N/1 sulphuric acid, after boiling and cooling, back titration with N/1 sodium hydroxide to methyl red indicator. CO_2 determined by precipitation with barium chloride at 70°, and titration of the barium carbonate with excess N/1 hydrochloric acid and N/1 sodium hydroxide to methyl orange indicator.

Ammonii Sulphocyanidum. *Syn.* AMMONII RHODANIDUM (Thiocyanas). $\text{NH}_4\text{SCN}=76.1$. White crystals soluble in water and alcohol. Reagent in toxicology to separate arsenic, antimony, mercury, etc., and in silver titrations.

Hydrazine. *Syn.* DIAMIDE. $(\text{NH}_2)_2=32.05$. In the basic condition this body is not stable, but the sulphate, $(\text{NH}_2)_2\text{H}_2\text{SO}_4$, is a well-defined stable salt—white crystals soluble in hot water. It is a useful reducing agent, e.g., in making colloidal metal hydrosols. It has antiseptic properties, e.g., it will destroy fungi, etc.

PHOTOGRAPHIC USE. Caldwell discovered that the inclusion of the salts of hydrazine, or hydroxylamine, in the emulsion renders a plate practically proof against over-exposure or reversal. Plates or papers treated with the hydrazine salts may also be printed right out and toned like ordinary P.O.P., or partly printed and the operation completed by development.

AMYGDALA AMARA

Oleum Amygdalæ (B.P.). Sp. gr., 0.915 to 0.920; $n_{\text{D}40^\circ}$, 1.4624 to 1.4650; acid value, not more than 4.0; saponification

value, 188 to 196; iodine value, 95 to 100. After remaining at -10° for 3 hours, it remains clear and does not congeal until about -18° . Complies with the tests for absence of apricot-kernel and peach-kernel oils, cottonseed oil, sesame oil and arachis oil. *Oleum Amygdalæ Expressum, U.S.P. XII*, has a sp. gr. of 0.910 to 0.915 at 25° ; it should remain clear at -10° and not congeal until nearly -20° ; saponification value, 190 to 200; iodine value, 95 to 105. No solidifying-point of the fatty acids is specified.

Detection of Persic Oil in Almond Oil. In *Oils, Fats and Fatty Foods*, E. R. Bolton with reference to oils of the almond group states, "The oils of this group are remarkably similar in all their properties and their detection in the presence of one another may be taken to be almost a practical impossibility" and "of the many tests which have been described for the purpose of achieving the impossible, probably Bieber's test is the least unsatisfactory." Many modifications of the test have been published. The following modification of the *B.P.* nitric acid test will detect the presence of 5% of apricot-kernel oil. Four drops of oil are shaken with 4 drops of chloroform, and two drops of fuming nitric acid are then added separately down the sides of the tube, with 10 seconds interval between each drop. Apricot-kernel oil gives an immediate blood-red colour changing to brownish-red; peach-kernel oil gives a red colour within one minute; almond oil, a light brown colour within two minutes. Fresh mixtures of almond oil with 5% of apricot oil give a brilliant red within 5 minutes; old mixtures require 15 minutes to develop the full colour. Peach-kernel oil is not a commercial article and is probably never used as an adulterant of almond oil.—*Z. anal. Chem.*, 1933, 94, 184.

The **Titre Test** is the determination of the solidifying-point of the fatty acids. In the *U.S.P. XI*, under tests for identity and purity, almond oil was required to have a solidifying-point of the fatty acids: not less than 9° and not more than 12° , exact details of the method of preparing the fatty acids and the apparatus to be used being specified. This requirement excludes almond oils which are undoubtedly genuine, such oils whilst they show a titre test at about 12° or under give a much more definite figure at about 6° . In neither case is the rise in temperature so definite as with some other oils such as palm kernel or coconut. The two figures are probably due to the formation of eutectic compounds in the mixture of fatty acids which are present.

Elaidin Test. A modification of this test in which the percentage of the elaidin crystallised from acetone, its melting-point, iodine value and saponification value are taken may be applied to almond oil, which yields 26.8 to 29.3% of elaidin with a melting-point of 38.5° to 39° ; iodine value, 78.5 to 79.5 and saponification value, 191.5 to 191.3. These figures differ distinctly from those of ground-nut oil and very widely from those of cottonseed oil. For further details of the test see elaidin test under olive oil (p. 293, this volume) and H. N. Griffiths and T. P. Hilditch, *Analyst*, 1934, 312.

Oleum Persicæ (B.P.C.). Sp. gr., 0.917 to 0.921; n_{D40}^{20} , 1.464 to 1.465; acid value, not more than 8; saponification value, 189 to 193; iodine value, 100 to 110. *Oleum Persicæ, U.S.P. XII*, must be labelled to indicate whether derived from apricot kernels or peach kernels. Sp. gr. at 25° , 0.910 to 0.918. Tests for paraffin oil, cottonseed oil and sesame oil are included. Saponification value, 185 to 195. Iodine value, 90 to 108. Does not become turbid at 15° .

Perilla Oil. The oil obtained by expression or extraction from the seeds of *Perilla ocymoides*, Fam. Labiatae, growing in China, India and Japan. The seeds contain from 36 to 43% oil. *B.S.S. No. 654—1936*, includes the following:—Sp. gr., 0.932 to 0.936; n_{D20}^{20} , 1.481 to 1.484; iodine value, not below 193; saponification value, not below 189; acid value, not above 6; unsaponifiable matter, not more than 1.5.

Oleum Amygdalæ Amaræ (B.P.C.). Contains not less than 85% *w/w* of C_6H_5CHO and the equivalent of 2 to 4% *w/w* of HCN . Sp. gr., 1.055 to 1.065. Refractive index at 20° , 1.534 to 1.542. Assayed by the *B.P.C.* method for benzaldehyde, in which standard hydroxylamine hydrochloride is added to the oil, and titrated with *N/2* alcoholic potassium hydroxide, using methyl orange as indicator, allowance being made for the free benzoic acid present. Hydrocyanic acid is determined by titration of the alcoholic solution, made slightly ammoniacal, with standard silver nitrate to a permanent opalescence with potassium iodide. A benzoic acid limit, equivalent to approximately 2%, is included and the oil should comply with the *B.P.C.* limit test for chlorinated compounds in Benzaldehydum. Nitrobenzene is tested for by reduction of an alcoholic solution with zinc powder and acetic acid, the presence of any aniline formed being detected by the odour of phenyl isocyanide on warming the mixture with chloroform and excess of sodium hydroxide. The *U.S.P. XII* requires a sp. gr. of 1.038 to 1.06 at 25° and the same strength of hydrocyanic acid; a lower standard of 80% of benzaldehyde is required, and is determined by addition to a neutralised solution of hydroxylamine hydrochloride in alcohol (60%) and titration with *N/2* alcoholic potash using bromophenol blue indicator. Hydrocyanic acid is titrated with silver nitrate, using potassium chromate as indicator, in the presence of magnesium sulphate and sodium hydroxide. Nitrobenzene is tested for by reduction to aniline as in the *B.P.C.* n_{D20° , 1.5428 to 1.5439.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined oil of bitter almonds, commercial, for food purposes, as the volatile oil from the seed of the bitter almond (*Amygdalus communis* L.), the apricot (*Prunus armeniaca* L.), or the peach (*Amygdalus persica* L.).—*S.R.A., F.D. No. 2, Rev. 5, Nov. 1936.*

In America, benzaldehyde is largely substituted for oil of bitter almonds. Frequently hydrocyanic acid in sufficient quantity is added to meet the requirements of the trade or the *U.S.P.* Adulteration with benzaldehyde can only be detected if the synthetic benzaldehyde contains chlorine. For method of assay see Salamon, *Perfum. essent. Oil Rec.*, 1917, 41. Much of the synthetic benzaldehyde is now produced by processes which do not involve the use of chlorine and is therefore free from that impurity. Benzaldehyde is considered to be inferior as a flavouring agent to natural oil of bitter almonds.

Small quantities of chlorine may be detected by a modification of the burning method; the combustion vapours being passed over silver gauze and the deposited silver chloride estimated.—Daudney, *Analyst*, 1935, 29.

Oleum Amygdalæ Amaræ sine Acido Hydrocyanico (B.P.C.). Estimated by the method for Benzaldehydum, should contain 95% by weight of C_6H_5CHO . Sp. gr., 1.048 to 1.052. Refractive index at 20° , 1.540 to 1.545. Limits for benzoic acid and nitrobenzene as for Oleum Amygdalæ Amaræ, and should not contain any hydrocyanic acid as shown by addition of sodium hydroxide and ferrous sulphate and acidification with hydrochloric acid, when no greenish blue colour or precipitate is produced. Complies with the test for chlorinated compounds in Benzaldehydum.

Oleum Amygdalæ Volatile Purificatum (*B.P. Add. II*). Contains not less than 95% of benzaldehyde, C_6H_5CHO . Soluble in 2 parts of alcohol (70%). Sp. gr. ($15.5^\circ/15.5^\circ$), 1.048 to 1.052. n_{D20° , 1.542 to 1.546. Tests for absence of hydrocyanic acid and for limit of chlorinated compounds are included. Determined by the *B.P.* process for aldehydes in volatile oils, using 0.5 g. of oil and 12 ml. of hydroxylamine hydrochloride reagent in alcohol (60%).

Benzaldehydum (*B.P.C.*). $C_7H_6O=106.0$. By titration of the acid liberated by interaction with N/2 hydroxylamine hydrochloride with N/2 alcoholic potassium hydroxide to methyl orange, and allowance for the free benzoic acid present, it contains not less than 90% of C_7H_6O . Sp. gr., 1.049 to 1.053; n_{D20° , 1.554 to 1.556. Complies with tests for hydrocyanic acid, nitrobenzene, chlorinated compounds and a limit of benzoic acid. The *N.F. VII* assays by a similar method and requires it to contain not less than 98% of C_7H_6O .

AMYLUM

Amylum (*B.P. Add. I*). Starch obtained from the grains of maize, *Zea Mays* Linn., or of rice, *Oryza sativa* Linn. Loss at 100° , not more than 14%. Ash, not more than 0.5%. Amylum, *U.S.P. XII*, is derived from the grain of *Zea Mays* Linné only. Moisture not more than 14% and ash not more than 0.5%. A trituration with 10 parts of water should be neutral to litmus paper. Complies with a limit test for iron—0.5 g. with 10 ml. distilled water, on the addition of 0.5 ml. of hydrochloric acid and 3 drops of potassium ferrocyanide solution, does not become blue within one minute.

For a gravimetric method for the determination of starch in substances generally, see J. J. Chinay, F. W. Edwards and H. R. Nanji, *Analyst*, 1934, 673.

Details with diagrams, of the microscopical structure of ten common commercial starches.—T. E. Wallis, *Pharm. J.*, ii/1933, 396.

Volumetric Method of Determination. Gelatinise the starch by heating with aqueous potassium hydroxide. Cool, dilute and adjust to a definite volume with water. Put a quantity in a centrifuge tube and make faintly acid to phenolphthalein with acetic acid. Add definite amounts of N/10 iodine, 2N potassium acetate and adjust with water to a definite volume. Centrifuge and pipette off part of the clear liquid and titrate with N/10 thiosulphate, using starch as indicator. Then titrate precipitate and liquid remaining in the tube. In calculating the result a factor is necessary because the composition of starch iodide varies with the excess of iodine left in contact with the precipitate. The factor is obtained from a specially prepared chart.—W. Whale, *Analyst*, 1938, 328–421.

Maranta (*B.P.C.*). Arrowroot is prepared from the rhizomes of *Maranta arundinacea* Linn. Loss at 100° , not more than 20%. Ash, not more than 0.3%.

The government of St. Vincent have defined arrowroot as the separated and purified starch of *Maranta arundinacea*. The starch similar to sweet potato starch with which arrowroot has been adulterated is obtained from "marble arrowroot," the bulbs of *Myrosma canifolia*. It is occasionally mixed with arrowroot by the growers.—P. H. Jones *Food*, 1934, 225.

ANETHUM

(with ANISUM and ANTHEMIS)

Anethum (B.P.). Contains not more than 2% of foreign organic matter, and not more than 11% of ash.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined dill seed as the dried fruit of *Anethum graveolens* L. Required to contain not more than 10% total ash, nor more than 3% ash insoluble in hydrochloric acid. —S.R.A., F.D. No. 2, Rev. 5, Nov. 1936.

Oleum Anethi (B.P.). Carvone content not less than 43% and not more than 63% by weight. Determined by the method of the B.P.: About 1.5 g. is accurately weighed into a stoppered tube, about 150 mm. long and 25 mm. diameter, 10 ml. of a hydroxylamine reagent (70 g. of hydrochloride in 900 ml. of 90% alcohol, 4 ml. of dimethyl yellow solution, sufficient N/1 alcoholic potash to produce the full yellow colour of the indicator, and alcohol to 1000 ml.) added, and placed in a water-bath at 75° to 80°; neutralisation of the liberated acid with N/1 alcoholic potash and further heating in the water-bath is continued alternately until the full yellow colour is permanent for 5 minutes heating (about 35 minutes total heating). A duplicate determination is performed using the first titration with an additional 0.5 ml. of N/1 alcoholic potash as colour standard for the titration end-point; from the second titration each millilitre of N/1 alcoholic potash is equivalent to 0.1513 (0.1501 × 1.008) g. of carvone. The Pharmacopœia requires the oil to be soluble in an equal volume of alcohol (90%, sp. gr. 0.8334 to 0.8340) and in 10 volumes of alcohol (80%, sp. gr. 0.8634 to 0.8640). Sp. gr., 0.900 to 0.915. Optical rotation, + 70° to + 80°. Refractive index at 20°, 1.481 to 1.492.

Few oils contain more than 60% of carvone.—*Perfum. essent. Oil Rec.*, ii/1932, 199.

A method of applying the hydroxylamine reaction in the determination of carvone in dill oil.—Bennett and Cocking, *Quart. J. Pharm.*, 1931, 580.

Anisum (B.P.C.). The dried ripe fruits of *Pimpinella Anisum* Linn. Contains not more than 2% of other seeds and fruits and not more than 1% of foreign organic matter; acid-insoluble ash, not more than 1.5%. Anisum, N.F. VII, contains not more than 3% of foreign organic matter and not less than 1.75% of volatile oil. Acid-insoluble ash, not more than 1.5%. No mouse-like odour, due to the presence of *Conium maculatum* fruit, develops when 1 g. is heated with 10 ml. of potassium hydroxide solution. Fructus Anisi, P.G. VI, yields not less than 1.5% of volatile oil.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined anise, aniseed, as the dried fruit of *Pimpinella anisum* L.; not more than 9% total ash or more than 1.5% ash insoluble in hydrochloric acid. Star aniseed was defined as the dried fruit of *Illicium verum* Hook., and contained not more than 5% total ash.—S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.

Oleum Anisi (B.P.). Distilled from Anisum or from the dried fruits of the star anise, *Illicium verum* Hook. f. Should be soluble in 3 volumes of alcohol (90%, sp. gr. 0.8334 to 0.8340), showing not more than a slight opalescence. Sp. gr. (20°/15.5°), 0.980 to 0.994. Optical rotation, - 2° to + 1°. Refractive index at 20°,

1.553 to 1.560. Freezing-point, not below 15°. M.p., not below 17°. Should comply with a limit for lead. Oleum Anisi, *U.S.P. XII*, may be distilled from the dried ripe fruits of either *Pimpinella Anisum* Linné or *Illicium verum* Hooker filius. Soluble with not more than a faint opalescence in 3 volumes of 90% alcohol, the similar solution of the recently distilled oil being neutral to litmus paper and developing no blue or brownish colour with 1 drop of ferric chloride solution. Sp. gr. at 25°, 0.978 to 0.988. Refractive index at 20°, 1.5530 to 1.5600. α_D at 20°, +1° to -2°.

The lead often contained in this oil is derived from the leaden containers in which most of the oil is imported.

Toxicity of Old Sample of Aniseed Oil. Old oil which can no longer be made to crystallise on cooling shown to be toxic on external application to animals.—Samdahl, *Quart. J. Pharm.*, 1932, 588.

Anthemis (B.P.C.). Dried double or semi-double flower heads of *Anthemis nobilis* Linn. Foreign organic matter, not more than 2%, and acid-insoluble ash, not more than 1%.

Oleum Anthemidis (B.P.C.). Soluble in 6 volumes of alcohol (70%, sp. gr., 0.8896 to 0.8901), forming a clear solution. Sp. gr., 0.905 to 0.915. Refractive index at 20°, 1.442 to 1.448. Acid value, 1.5 to 14.0. Saponification value, 260 to 296.

Matricaria (B.P.C.). Dried flowerheads of *Matricaria chamomilla* Linn. Contains not more than 8% of its stems and other foreign organic matter. Yields not more than 4% of acid-insoluble ash. The *N.F. VII* allows 10% of stems and not more than 2% of other foreign organic matter in *Matricaria*; the acid-insoluble ash limit is 4%.

ANTIMONIUM

Antimonii Oxidum (B.P.C. Supp. IV). $Sb_2O_3 = 291.5$. As assayed by titration with N/10 iodine of a solution in dilute hydrochloric acid, with the addition of sodium potassium tartrate and a slight excess of sodium bicarbonate, it contains not less than 95% of Sb_2O_3 . Completely soluble when boiled with excess of potassium acid tartrate solution.

Acid-Resistance Test for Enamel. The solubility of enamel on enamelled ironware is dependent on the strength of the solutions of organic acids with which it comes in contact. It should be free from antimony, lead, arsenic, and other deleterious or poisonous ingredients. Acid-resistance may be controlled by the following test:—"Enamelware vessels will be considered to be sufficiently resistant to acid if, when filled as full as is convenient with a boiling 0.5% solution of citric acid in water and allowed to stand for 24 hours without being heated or artificially cooled, the amount of ash yielded on ignition of the residue obtained when a definite proportion of the solution is evaporated does not exceed 1.0 mg. per sq. cm. of surface exposed to the action of the acid, and if on repetition of the treatment with a fresh similar volume of the boiling acid solution not more than a further 0.5 mg. per sq. cm. is obtained." Antimony should be absent from the constituents used in making the enamels. Acid extracts may contain appreciable quantities of borax and significant amounts of fluorine and the exclusion of constituents containing these elements is desirable.—J. H. Coste and D. C. Garratt, *Analyst*, 1935, 215.

The determination of antimony compounds extracted from enamelware by citric acid solution.—R. H. Burns, *Analyst*, 1935, 220.

Antimony Detection in Biological Liquids. The reagent used is 1 g. of phenazone and 2 g. of potassium iodide in 30 ml. of water. Biological fluids are evaporated and ignited, the residue dissolved in hydrochloric acid and the

reagent added; 0.025 mg. of antimony can be detected.—*J. chem. Soc. Abstr.*, ii/1923, 587.

Determination. The antimony solution, mixed with twice its volume of reagent (100 g. sodium thiosulphate, 200 ml. of water and 150 ml. of sulphuric acid) is heated on a water-bath for 30 minutes. It is filtered through a sintered glass crucible, washed with 25% sulphuric acid, and the precipitate, antimony, dissolved by passing an excess of N/10 iodine containing 1 ml. of 10% tartaric acid through the crucible. A volume of standard arsenite solution, equivalent to the volume of iodine solution used is added with sodium bicarbonate and the excess arsenite titrated with N/10 iodine. The reaction can also be used as a nephelometric means of determination. To determine antimony in the presence of arsenic, the total arsenic is determined, the combined arsenic and antimony precipitated by the above process is determined and also the arsenic remaining in the filtrate, because only about one-third of the arsenic present is precipitated.—L. Fauchon and L. Vignoli, *J. Pharm. Chim., Paris*, 1937, 25, 541.

Antimonii et Potassii Tartras (B.P.). $C_4H_4O_7SbK, \frac{1}{2}H_2O = 333.9$. Should contain not less than 99% of the pure substance. Assayed by titration of the aqueous solution with N/10 iodine, with the addition of sodium bicarbonate and using starch mucilage as indicator. It is required to comply with a test for alkalinity or acidity by which 1 g. requires for neutralisation to the green colour of bromocresol green indicative of pH 4.5 not more than 2.0 ml. of either N/100 sulphuric acid or N/100 sodium hydroxide. The U.S.P. XII substance is required to be of the same purity; the usual limit test for arsenic, is not used for this substance. 0.1 g. of the salt is dissolved in 5 ml. of hydrochloric acid and 10 ml. of a solution containing 20 g. of stannous chloride in 30 ml. of hydrochloric acid added. After mixing, the tube is allowed to stand 30 minutes and the colour developed is then compared with that of a similar tube containing none of the antimony compound but to which has been added 0.02 mg. of arsenic trioxide. Viewed downward over a white surface the colour of the mixture is not deeper than that of the standard tube. *Tartarus stibiatus, P.G. VI*, contains not less than 99.5% of $C_4H_4O_7SbK, \frac{1}{2}H_2O$.

Antimonii et Sodii Tartras (B.P.). $C_4H_4O_7SbNa = 308.8$. Loses not more than 5% of its weight at 100° and then contains not less than 96% of $C_4H_4O_7SbNa$. The same limit of acidity or alkalinity as for the potassium compound is included and the same method of assay is used. No limit of arsenic is specified.

Stibophenum (B.P. Add. III). $C_{12}H_4O_{16}S_4SbNa_5, 7H_2O = 895.1$. Contains 15.6 to 16.0% of trivalent antimony and 16.5 to 16.9% of sulphur, calculated on the dried substance. Complies with tests for limit of calcium, absence of chloride, and of sulphate. Loss on drying at 140° to 150° in a vacuum, 14 to 16%. Trivalent antimony determined by addition of excess iodine solution to a solution in dilute acetic acid and back titration with standard sodium thiosulphate. Sulphur determined by ignition with potassium hydroxide and potassium nitrate and precipitation as sulphate.

ORGANIC ANTIMONY COMPOUNDS.

Biological Tests. These substances are tested biologically for toxicity and therapeutic potency in the same way as are the organic arsenicals.

Toxicity Tests. Toxicity tests are usually carried out on mice by injection into the tail vein, and the dose is determined which kills 50% of mice.

Therapeutic Potency. Tests for therapeutic potency may be made as described for nearsphenamine, but a better method has been described by Gray, Trevan, Bainbridge, and Attwood (*Proc. roy. Soc., Ser. B.*, 1931, 108, 54). Mice are infected with trypanosomes, but a smaller dose of infected material is given than for the nearsphenamine test. Instead of leaving the mice for two days during which the infection develops unchecked, the agent to be examined is injected at once, ten infected mice each receiving the same dose, and ten other mice each receiving a dose of the substance used as a standard of comparison. No daily examination of the blood of the mice is made, but the number of days each mouse survives is observed. The average period of survival of mice injected with the substance being tested is determined, and also the average period of survival of mice injected with the standard. Should these average survival times not be the same, the experiment is repeated until a dose of the sample is found which gives an average survival time about equal to that given by the chosen dose of the standard.

AQUA DESTILLATA

Aqua Destillata (B.P.). Residue on evaporation on a water-bath, not more than 0.001%. After 5 minutes 10 ml. portions show no reactions for chlorides and sulphates with silver nitrate and barium chloride solutions respectively. 100 ml. (testing for lead, copper and iron) should remain clear and colourless with 1 drop of sodium sulphide solution. Limit of ammonia (1 part NH_3 in 2.5 millions) by Nesslerising 50 ml. Oxidisable matter is limited by boiling 100 ml. for 10 minutes with permanganate, when the colour should not be completely destroyed. The *U.S.P. XII* water should have a pH of 5.0 to 7.0, as shown by the reactions to methyl red and bromothymol blue pH indicators: residue on evaporation and drying at 100° , not more than 0.001%. Tests for sulphate, chloride, calcium, heavy metals, ammonia and carbon dioxide are included.

Aqua Sterilisata (B.P. Add. I). The distillate (excluding the first portion) collected in a sterilised neutral glass container, obtained from potable water using a glass still, or one in which the distillate is not in contact with copper, cleansed immediately before use. Should be sterilised by heating in an autoclave, closing the container with a plug of sterile non-absorbent cotton wool wrapped in gauze, by fusion of the glass or other effective method. When stored in a container closed with cotton wool it may be used within one month only. On using part of the contents of a container the remainder may be stored after sterilisation. For use within 24 hours it may be prepared by boiling for 30 minutes in a plugged container. Complies with tests for sulphates, chlorides, for lead, copper and iron, ammonia, oxidisable matter and residue. Aqua Destillata Sterilisata, *U.S.P. XII*, complies with the tests for distilled water and the sterility test for liquids of the *U.S.P. XII*. It is not to be used for parenteral administration or in preparations used parenterally.

Distilled water for parenteral injections. Reports of the production of rise of temperature and rigors following the intravenous injection of large volumes of perfusion fluids are not

uncommon. It was first investigated by Wechselmann (1911) in respect of Salvarsan-saline injections. Bacteria can multiply in sterile distilled water, though they ultimately die. It is unlikely that pyrogenic symptoms arise from the presence of protein from dead bacteria. Seibert (*Amer. J. Physiol.*, 1923, 67; *ibid.*, 1925, 71) in a series of papers investigated several suggested causal factors and eliminated the following: alkalinity from the glass vessels, the extractive matter from ordinary corks, gases such as CO₂, O₂, H₂S, NO₂, hæmolysis of the blood due to hypotonicity, the pH of the solutions. She concluded that the causal factor must be of bacterial origin, and showed that all waters, tap or distilled, were not pyrogenic. The causative organisms were certain water-borne bacteria producing an excretory product, *pyrogen*, which was capable of passing the usual bacterial filters and was very thermostable; long and drastic heating such as refluxing for 7 hours was necessary to destroy it. Unless a water-still is provided with a splash head, pyrogen may be carried over to give a pyrogenic distillate. It is also possible for the condenser to become contaminated with living pyrogenic organisms and for the distillate to contain them. Such a distillate would develop its maximum pyrogenic properties in 4 days. *Hence it is essential that distillation should be followed by immediate sterilisation.* This will prevent the development of pyrogen in the distillate.

The British Pharmacopœia (*Add. I*) specifies immediate sterilisation of fresh distillate in the preparation of sterilised water and places no limit of storage on such water if stored in hermetically sealed containers.

It is possible that pyrogenic symptoms may also be due to other causes. Thus Hyman and Hirschfeld (*J. Amer. med. Ass.*, ii/1933, 305) and Hirschfeld (*Arch. int. Med.*, 1931, 47, 259) claim that an excessive speed in injecting can cause a syndrome which they term "speed shock."

Aqua Pro Iniectione (*U.S.P. XII*), is water which has been distilled and sterilised within 24 hours and is for parenteral use. It is stored in sealed or other suitable containers, so that it is free and remains free from pyrogens. Complies with the physical and chemical standards of Aqua Destillata, *U.S.P. XII*, and with the sterility test for liquids. A special pyrogen test is included; 10 ml. per kg. body weight is injected intravenously into healthy rabbits and hourly observations of the body temperature are made. Not less than 5 animals are used and the test is positive if 3 animals out of 5 show an individual rise in temperature of 0.6°C. or more above the normal previously established for the animals. If 2 animals out of 5 show a positive response, a further 5 animals must be tested and the test is positive if 2 out of the second group show a positive response. Strictly controlled conditions must be observed in carrying out the test.

The pyrogen found in infusion fluids is of a particulate nature, of a larger order of magnitude than 50 millimicrons but smaller than one micron. There are now available two processes of filtration which effectively remove the reactive agent from infusion fluids. One is ultrafiltration which, however, is

too slow and too difficult for clinical use, and the other s adsorptive filtration through two layers of Seitz serum No. 3 filter pads (compressed asbestos), which is easy to manipulate and should be feasible for use in hospitals and commercial houses. The new process may be summarised as follows: Distillation → addition of chemicals → adsorptive filtration → sterilisation.—Co Tui *et al.*, *J. Amer. med. Ass.*, ii/1937, 250.

Pyrogen-free water may be prepared in an emergency by shaking the water for fifteen minutes with an adsorption agent and then passing through a sintered glass filter. Activated powdered charcoal, 1 g. per l. of water, was highly effective in removing pyrogens.—J. C. Lees and G. A. Levvy, *Brit. med. J.*, i/1940, 430.

Pyrogens may sometimes occur in medicaments themselves. This fact is largely overlooked, and solutions may be contaminated by the solute after very careful preparation of the distilled water. Substances such as dextrose are particularly liable to contamination and require special precautions. In the preparation of non-pyrogenic solutions, distillation was used to obtain non-pyrogenic water, and the method of Lees and Levvy, of adsorbing pyrogens on activated charcoal, to deal with pyrogens in the medicaments. Biological tests confirmed the efficiency of the method.—J. P. Todd, *Pharm. J.*, i/1941, 258.

ARECA

Areca (B.P.C.). The dried ripe seeds of *Areca Catechu* Linn. The *N.F. VII* requires Areca to contain not more than 2% of adhering pericarp, not more than 1% of foreign matter, not more than 2.5% of ash, and not less than 0.35% of ether-soluble alkaloids calculated as arecoline. The drug in powder is assayed by shaking with ether in the presence of ammonia followed by addition of anhydrous sodium sulphate and further shaking. The ether solution is then decanted, shaken with talc and allowed to stand. An aliquot portion of the ether solution is decanted, extracted with N/50 sulphuric acid and washed with water. The combined acid and washings are then titrated against N/50 sodium hydroxide using methyl red as indicator. *Semen Arecæ, P.G. VI*, assayed by the process prescribed, contains not less than 0.4% of alkaloid, calculated as arecoline. *Semen Arecæ, P. Helv. V*, contains not less than 0.4% of alkaloids.

P.G. VI Assay. Digest 8 g. of powdered areca with 80 g. of ether, and 4 g. of ammonia solution (9.94 to 10%) and shake the mixture for 10 minutes. After the addition of 10 g. of anhydrous sodium sulphate shake for 5 minutes, pour off the ethereal solution immediately from the mixture, add 0.5 g. of talc, shake for 3 minutes, add 2.5 g. of water and shake. Pour off 50 g. of the dry ethereal solution into a small flask and distil off two-thirds of the ether. Run the cold residue into a separating funnel, rinsing the flask three times with 5 ml. of N/10 hydrochloric acid and 5 ml. of water. After shaking for 3 minutes, let the hydrochloric acid become completely clear, run off into a flask and then repeat the shaking three times in the same manner with 5 ml. of water. Now add to the hydrochloric acid 2 drops of methyl red solution and titrate with N/10 potassium hydroxide until the colour changes. Not more than 3.71 ml. of N/10 potassium hydroxide should be used, since 1.29 ml. of N/10 hydrochloric acid is equivalent to 0.4% of alkaloid. (1 ml. N/10 HCl = 0.015511 g. of alkaloid).

P. Helv. V Assay. The powdered drug is defatted with light petroleum and then extracted with ether; the dried ethereal extract is extracted repeatedly with standard dilute hydrochloric acid and the excess of acid titrated with N/10 sodium hydroxide using methyl red as indicator. Each millilitre of N/10 HCl is equivalent to 0.0155 g. of alkaloid.

Arecolinæ Hydrobromidum (N.F. VII). $C_{12}H_{19}O_2N.HBr = 236.1$ Loss over sulphuric acid for 24 hours, not more than 1%. Ash, not more than 0.5%.

Tests for free acid, other alkaloids and sulphates are included. Bromhydrate d'Arécoline, *Fr. Cx.* 1937, melts at 170°, and the chloroplatinate at 176°, and complies with an ash limit and a test for foreign alkaloids.

Arecolinum hydrobromicum, *P. Helv. V.*, contains 99.4% of $C_8H_9O_2N.HBr$ and is assayed by titration with N/10 sodium hydroxide. M.p., 169° to 171°.

Methods for the determination of arecoline and other constituents of areca nut.—P. Bourcet, *Brit. chem. Abstr. B.*, 1933, 1035.

ARGENTUM

Argenti Nitras (B.P.). $AgNO_3=169.9$. Contains not less than 99.8% of the pure salt. Titrated with N/10 ammonium thiocyanate, using ferric ammonium sulphate as indicator. A limit of copper, bismuth and lead is included. The *U.S.P. XII* also requires a purity of 99.8%.

Detection of Silver. The presence of silver may be shown by means of *p*-dimethylaminobenzylidenerhodanine (*syn. p*-dimethylaminobenzalrhodanine). The reagent is used as a 0.03% solution in acetone. To 20 ml. of the approximately neutral test solution add 2 ml. of N/1 nitric acid and 0.5 ml. of the reagent. The presence of silver is denoted by the production of a reddish coloration. In the presence of mercuric compounds 0.5 ml. of N/1 hydrochloric acid must be added after the reagent. In the presence of gold, platinum or palladium 0.5 ml. of 10% potassium cyanide solution must be added to the test solution, followed by the reagent and then the nitric acid. If copper is present, it must be oxidised to the cupric state, no coloration being then produced in acid solution. Cuprous ions give a violet precipitate or coloration.

Argenti Nitras Induratus (U.S.P. XII), by titration of the water-soluble portion with ammonium thiocyanate, contains 94.5% of $AgNO_3$.

Liquor Argenti Nitratiss Ammoniacalis (N.F. VII). Contains 28.5 to 30.5% w/w of Ag and from 9.0 to 9.7% w/w of NH_3 .

Argentoproteinum (B.P. Add. I). Contains from 7.5 to 8.5% of Ag. Assayed by titration with tenth normal ammonium thiocyanate of the slowly incinerated residue heated with nitric acid till no more coloured fumes are evolved, and diluted. The filtrate from 1 g. shaken with 10 ml. of alcohol (90%) should produce no turbidity on the addition of 2 ml. of dilute hydrochloric acid. Argentum Proteinicum Forte, *U.S.P. XII*, contains from 7.5 to 8.5% of silver. The following test for distinction from Mild Protein Silver is included:—7 g. of ammonium sulphate is added to 1 g. in 10 ml. of water and stirred for 30 minutes. After filtration, to the clear liquid is added 25 ml. of 1% acacia solution. The turbidity produced on adding 2 ml. of nitric acid and 2 ml. of diluted hydrochloric acid and acacia solution to 50 ml. is *not* greater than that produced by similarly treating 10 ml. of water with 1.6 ml. of N/100 silver nitrate.

Argentum colloidal, *P.G. VI*, contains not less than 70% of silver and Argentum proteinicum contains at least 8%. Argentum colloidal, *P. Helv. V.*, contains not less than 70% of silver, and Argentum proteinicum, *P. Helv. V.*, from 8.0 to 8.3%. The silver is converted by careful ignition and subsequent treatment with nitric acid into silver nitrate which is then titrated with ammonium thiocyanate using iron alum as indicator. Argent colloidal par voie chimique, *Fr. Cx.* 1937, assayed by oxidation with sulphuric acid and potassium permanganate and titration with N/10 ammonium thiocyanate, contains not less than 70% Ag.

Argenti Proteinis Mite (B.P.C.). Assayed by the method for the stronger proteinate, contains from 19.0 to 25.0% of Ag.

It complies also with a limit test for silver salts. Argentoproteinicum Mite, *U.S.P. XII*, contains 19 to 23% of Ag. The turbidity produced in the same test for distinction used for the strong preparation of the *U.S.P. XII*, should be *no* greater than the control test. (*Note*.—Obviously, one of these two tests for distinction is wrongly stated in the *U.S.P. XII*.)

Official methods for the determination of total silver and ionisable silver compounds in silver proteinates are described in *Methods of Analysis* (*A.O.A.C.*, 1940, 624).

Preparation of Colloidal Silver and Silver Proteinate. Add slowly with constant stirring 1 kg. of casein to a hot solution of 0.5 kg. sodium hydroxide solution (40° Bé, sp. gr. 1.383) and 2 l. of water. Dilute with half its volume of water, cool and filter. Acidify with nitric acid diluted with 2 parts of water and knead the precipitated protalbic acid with water to remove nitric acid, adding the washings to the mother-liquor which contains lysalbic acid. Dissolve the protalbic acid in warm water containing ammonium hydroxide, re-precipitate with nitric acid and repeat the solution and precipitation until a pearly, wax-like substance results. This is again dissolved in ammonia, the solution filtered and evaporated and the protalbic acid dried to constant weight at 105° (yield about 160–170 g.). Dry protalbic acid 19 g. in 15% solution is mixed thoroughly with silver oxide freshly precipitated from 100 g. of silver nitrate by means of sodium hydroxide, and washed free from nitric acid by decantation. Add to the mixture 18 g. of sodium hydroxide and 3 to 5 ml. of solution of ammonia (sp. gr. 0.910) and heat on a water-bath at 80° until a portion of the liquid diluted with water is faintly opalescent by reflected light, but clear by transmitted light. The solution is dialysed for two days and then dried in thin layers at 60° to 80°. Yield about 80 g.

For Silver Proteinate. The mother liquor and washings obtained as above are dialysed free from nitrates. The liquid is neutralised to phenolphthalein with sodium hydroxide, and the proportion of lysalbic acid determined by drying a portion of the solution at 105° and ashing the dry powder; the difference between the weights of ash and dry powder gives the lysalbic acid. Lysalbic acid 1 kg., is diluted with water to form an 8% solution to which is added a solution of 155 g. silver nitrate in 500 g. of water. The mixture is heated on a water-bath at 80° until clear, and is then diluted and dialysed for five days. The liquid is evaporated under reduced pressure to the consistence of a thick syrup, solution of hydrogen peroxide is added slowly with constant stirring until the desired light brown colour is obtained, and the product is dried below 60°, preferably under reduced pressure.—R. A. Feldhoff, *Apoth. Ztg.*, 1933, 83, 1205.

ARNICÆ FLOS

Arnicae Flos (B.P.C.). The dried flowerheads of *Arnica montana* Linn. Contains not more than 2% of foreign organic matter, and the percentage of receptacles with their attached involucre is not less than 25 and not more than 33. Yields not less than 15% of alcohol-soluble extractive (45% alcohol) by macerating 5 g. of the air-dried drug, in coarse powder, with 100 ml. of the alcohol for 24 hours, with frequent shaking, filtering and evaporating 25 ml. to dryness and drying at 100°. *Arnica*, *N.F. VII*, should contain not more than 3% of foreign organic matter, and yield not more than 2% of acid-insoluble ash.

Arnicae Rhizoma (B.P.C.). The dried rhizome and rootlets of *Arnica montana* Linn. Should not contain more than 2% of foreign organic matter. Ash, not more than 12%. Yields not less than 14% of alcohol-soluble extractive (0% alcohol).

ARSENUM

Arseni Triiodidum (B.P.). $\text{AsI}_3=455.7$. As determined by titration with N/10 iodine in presence of sodium bicarbonate, it contains not less than 99.0% of the pure substance. At 100° it should not lose iodine, and on volatilisation not more than 0.5% of residue remains. **Arseni Triiodidum, N.F. VII**, after drying to constant weight over sulphuric acid, is of the same strength. **Triiodure d'Arseñic, Fr. Cx.** 1937, assayed for iodine and for arsenic content, contains not less than 99% of AsI_3 .

Liquor Arseni et Hydrargyri Iodidi (B.P.) contains 0.95 to 1.05% w/v of red mercuric iodide and total arsenic equivalent to 0.95 to 1.05% w/v of arsenic triiodide. Assayed for arsenic by addition of sodium bicarbonate, exactly oxidising the arsenic with N/10 iodine, followed by addition of hydrochloric acid and, after 10 minutes, titration with N/10 sodium thiosulphate. 1 ml. N/10 sodium thiosulphate = 0.02279 g. of total arsenic, calculated as AsI_3 ; mercury is determined by precipitation as sulphide in ammoniacal solution.

Arseni Trioxidum (B.P.). $\text{As}_2\text{O}_3=197.9$. Contains not less than 99.8% of As_2O_3 . Residue on volatilisation, not more than 0.1%. Assayed by dissolving in boiling water and N/1 sodium hydroxide, adding an equal quantity of N/1 hydrochloric acid and then sodium bicarbonate, and titrating with N/10 iodine. Arsenious sulphide should be absent as shown by the substance forming a clear colourless solution in 20 parts of dilute solution of ammonia, which does not become yellow when diluted with an equal volume of water, and acidified with hydrochloric acid. **Arseni Trioxidum, U.S.P. XII**, should contain not less than 99.5% of the pure substance after drying to constant weight at 100° .

Tabellæ Arseni Trioxidi (N.F. VII). Contain 92.5 to 107.5% of the labelled amount of arsenic trioxide, including all tolerances. Assayed by boiling with water, cooling and then adding hydrochloric acid, allowing to stand 2 hours and finally titrating with M/50 potassium iodate, using chloroform as indicator.

Liquor Arsenicalis (B.P.) contains 0.95 to 1.05% w/v of As_2O_3 , as shown by titration with N/10 iodine. **Liquor Acidi Arsenosi, U.S.P. XII**, assayed similarly, contains 0.975 to 1.025% w/v of As_2O_3 .

During the preparation of **Liquor Arsenicalis** nearly half the arsenious oxide combines with the alkali to form meta-arsenite, KAsO_2 , the remainder dissolving uncombined in the meta-arsenite solution. On neutralising with acid the compound is decomposed, the final product consisting simply of a solution of arsenious oxide and potassium chloride.—C. Morton, *Quart. J. Pharm.*, 1933, 4.

Liquor Potassii Arsenitis (U.S.P. XII) contains 0.95 to 1.05% w/v of As_2O_3 .

Ferri Arsenas (B.P.C.). Assayed by titration in diluted sulphuric acid solution with potassium permanganate, it contains not less than 10% of ferrous iron calculated as $\text{Fe}_3(\text{AsO}_4)_2$. **Arséniate de Fer, Fr. Cx.** 1937, contains 29 to 31% of arsenic, by precipitation as magnesium ammonium arsenate, and 32 to 34% of iron.

An official method for the determination of arsenic in iron-arsenic tablets is described in *Methods of Analysis (A.O.A.C., 1940, 615)*.

Sodii Arsenas Anhydrosus (B.P.C.). $\text{Na}_2\text{HAsO}_4 = 185.9$. Loses not more than 2% at 150° and then contains not less than 99.5% of the pure compound. Assayed by interaction with potassium iodide in a 50% hydrochloric acid solution, and titration of the liberated iodine with standard sodium thiosulphate. The crystallised salt of the International Protocol contains 36.85% of arsenic acid. Sodii Arsenas Exsiccatus, *N.F. VII*, is required to contain not less than 98% of Na_2HAsO_4 , after drying to constant weight at 150° ; loss at 150° , not more than 3%; in assaying, the interaction with potassium iodide is allowed to proceed during 15 minutes and at a temperature of 80° , with a concentration of hydrochloric acid of only approximately 30%. Arséniate de Sodium Officinal, *Fr. Cx. 1937*, is the heptahydrate; assayed by precipitation with magnesia mixture, contains not less than 58.4% of the anhydrous substance.

Arsenical Sprays. Lead arsenate is used much for fruit-tree spraying, as is also calcium arsenite. Paris Green, *syn.* Schweinfurth Green, Emerald Green, Mitis Green or French Green, i.e., copper aceto-arsenite, is also used. The sale of arsenical preparations should be limited to registered pharmacists and to persons who obtain a licence for the possession of same.—Sir W. H. Willcox, *Brit. med. J.*, ii/1922, 371.

Lead Arsenate. The specification of the Association of British Insecticide Manufacturers (Bulletin No. 82, Ministry of Agriculture and Fisheries) for lead arsenate (di-plumbic arsenate, PbHAsO_4) requires lead arsenate powder to be in the form of fine powder free from lumps and grit, and to contain not less than 31% of arsenic calculated as arsenic pentoxide, As_2O_5 , not less than 63% of lead oxide (PbO) and not more than 0.5% of water-soluble arsenic expressed as As_2O_5 . A limit test for acidity is also prescribed. Lead arsenate paste consists essentially of a mixture of di-plumbic arsenate and water; it should contain not less than 14% of arsenic (As_2O_5) and not less than 28.4% of lead oxide (PbO). It should comply also with tests for acidity and a limit of 0.5% of water-soluble arsenic.

Arsine in Industry.

Arseniuretted hydrogen is formed chiefly in industrial processes when metals or other reducing bodies containing traces of arsenic are dissolved in acids. It is a colourless gas with a faint odour resembling garlic and this may pass undetected. It is a very poisonous gas with a delayed action, whilst it is also believed to be cumulative in effect. Symptoms develop a few hours after exposure and are even then usually indefinite with a feeling of giddiness, headache, nausea, and possibly severe vomiting. The mortality of diagnosed cases of arsine poisoning is about 30%. Arsine is absorbed by the hæmoglobin of the red blood corpuscles, causing hæmolysis, with the result that the arsenic is oxidised, whilst hæmoglobin and albumen, and occasionally blood, appear in the urine. Later symptoms are a jaundiced skin the rapidity and depth of appearance of which depend on the seriousness of the condition. Fatal results occur from exposure to 2.5 parts in 10,000 for half an hour, whilst exposure to 1 part in 20,000 for 1 hour is dangerous and to 1 part in 100,000 for 12 hours is fatal.

Treatment. On account of the delayed action of this gas there is no question of first aid. Treatment consists in blood transfusion to counteract the severe anæmia and the administration of copious draughts of liquid and alkalis, such as sodium citrate (180 to 240 gr. in 24 hours), to increase the flow of urine and assist in the elimination of arsenic. **Detection and Determination.** Arsine is best detected by mercuric chloride or bromide papers, using lead acetate as a filter for hydrogen sulphide if necessary, when the well-known yellow to orange colour of mercuric arsenide is obtained. (*Toxic Gases in Industry*, No. 9, D.S.I.R.)

Arsine Derivatives.

Many cases of poisoning have been reported due to wallpapers containing arsenic and one has been recorded, where the wall was composed of coke breeze and cement. In every instance the walls were damp and it has been shown that the liberation of arsenic is due to the action of mould growths and the formation of substituted arsines, of which the dimethyl and trimethyl and the diethyl arsines are the most important. These gases possess a strong odour of garlic and it has been suggested that the production of trimethylarsine by the growth of *Penicillium brevicaulis* on media, to which has been added a small quantity of the material to be examined, is as sensitive as the Gutzeit test.

At the present time arsenical derivatives are considered primarily as war gases and some of them were actually employed towards the end of the 1914-18 war. In the main, however, it has been decided that only organic derivatives of arsine are likely to be useful and it is doubtful whether more than seven of these are likely to be employed intentionally. The aliphatic compounds are: methylchloroarsine (*Methyl Dick*), ethylchloroarsine (*Dick*), and Chlorovinylarsines (*Lewisite*). The aromatic arsines are: Phenylchloroarsine, diphenylchloroarsine, and diphenylcyanoarsine. One heterocyclic arsine may be employed: diphenylaminechloroarsine. Ethylchloroarsine ($C_2H_5AsCl_2$) was used to a slight extent by the Germans in the last war in an attempt to combine the vesicant properties of mustard gas with the lung irritant properties of phosgene. It is an extremely irritant gas. The methyl compound was not used in the last war, but is similar in behaviour to the ethyl compound, though less than half as toxic.

Lewisite, (2-chlorovinyl dichloroarsine, $ClCH=CH\cdot AsCl_2$) was being manufactured in America in the last war, but has not been actually employed in war. In the pure state it is a colourless, oily liquid. M.p., -13° ; b.p., 190° (decomp.). In the impure state it is a heavy brown liquid with an odour strongly reminiscent of geraniums. It is soluble in ordinary organic solvents and is hydrolysed by water and alkalis. It can be detected fairly readily by hydrolysing with 10% caustic soda, when acetylene is given off and sodium arsenite is formed. If the acetylene is allowed to pass through or to diffuse over a freshly prepared solution containing 1.5% copper sulphate, 3% ammonium chloride, 20%

ammonium hydroxide solution 10%, and hydroxylamine sulphate 5%, a brick-red precipitate of copper acetylide is formed. The arsenic in the remaining solution can be reduced by the modified Gutzeit reaction and detected as mercuric arsenide. Lewisite is a sensory irritant and capable of producing burns similar to those of mustard gas, but irritation is produced almost immediately by liquid on the skin and blisters develop much more rapidly than in the case of mustard gas. The burns heal more rapidly than do those caused by mustard gas, though, if extensive, they may be complicated by the danger of arsenical poisoning. In the production of Lewisite the di- and tri-vinyl arsines are almost always produced. Monochlorovinyl dichloroarsine and dichlorovinyl monochloroarsine possess very similar physiological action, but the trichlorovinyl arsine has practically no aggressive action.

Determination of organic arsines in foodstuffs, etc. The only organic arsine which is readily decomposed is Lewisite and as this may be impure or mixed with another arsenical it is necessary to break down the contaminated material by organic combustion, which converts the arsenic to the arsenical condition, which must be reduced by sulphur dioxide or other process before the arsenic can be determined by the modified Gutzeit process.

TESTS FOR ARSENIC

The modified Gutzeit Test is used in the B.P. '32 and B.P.C. '34 with precise directions, and a list of limits of arsenic in the substances to be tested is given in parts per million.

Modification of Gutzeit Test. A new apparatus in which the tube containing the mercuric chloride paper is surrounded by a cooling system. Increased evolution of hydrogen is obtained by adding a ferrous salt and stannous chloride to the zinc and acid.—H. E. Crossley, *J. Soc. chem. Ind., Lond.*, 1936, 272T.

Marsh's Test consists in generating hydrogen electrolytically or by means of acid and zinc, and adding the substance to be tested. If arsenic be present arseniuretted hydrogen is evolved, and deposits metallic arsenic in the cooler parts of the delivery tube, which is heated at a suitable point.

The sensitiveness of zinc is invariably increased by the use of cadmium sulphate and the use of this salt must be regarded as an essential and inseparable feature of the Marsh-Berzelius process.

Both Marsh's Test and the B.P. method are unreliable. Accurate results may be obtained by the method of Martin and Pien (*Bull. Soc. chim. Fr.*, 1930, 646).—Ch. Bertin, *Ann. Falsif.*, 1938, 215.

Estimation of arsenic especially with regard to determination in the tissues. Zinc is unsatisfactory. The arsenic, e.g., in a Marsh, does not appear until the experiment has proceeded for a period of time. The suggestion that there may be deposits or nuclei of arsenic in impure zinc is certainly good. The electrolytic apparatus of Thorpe is preferable to Marsh.—G. Roche Lynch, *Lancet*, ii/1922, 629.

Keratin tissues take up a proportionately greater amount of arsenic than other tissues of the body.—Prof. Sydney Smith, Sect. of Forensic Medicine, B.M.A. Cent. Meeting, 1932, *Brit. med. J.*, ii/1932, 320.

Reinsch's Test consists in heating the substance with concentrated hydrochloric acid and copper foil; the arsenic is deposited as arsenide on the foil from which it may be sublimed after washing and drying.

The Reinsch test forms a useful basis for a rapid sorting test where a large number of samples of foodstuffs are to be examined for arsenic by the Gutzeit or electrolytic technique. The method recommended is to dilute, if necessary, a suitable aliquot portion of the reduced and diluted acid digest from the nitric acid and sulphuric acid oxidation of a known weight of foodstuff to 7 ml.

with water, and add 3 ml. of conc. hydrochloric acid. The liquid is boiled for not less than 2 minutes with a flat strip of copper foil, which has been previously cleansed by boiling with hydrochloric acid (1 : 1) and rinsed with water. The foil is then washed with water, marked for identification and placed in a shallow white dish containing N/4 hydrochloric acid. It is compared with similarly prepared standards.—J. G. A. Griffiths, *Analyst*, 1941, 491.

Biological Test. The addition of a substance containing a trace of arsenic to a growing culture of *Penicillium brevicaulis* causes in a few minutes an evolution of arsine which can be detected by the smell. 0.0000001 g. of As can be detected.—B. Gosio, *Boll. Ist. sieroter. Milano*, 1932, 61, 597.

The gas evolved is trimethylarsine.—F. Challenger *et al.*, *J. chem. Soc.*, 1933, 95.

The second report of the Commission Internationale des Spécialités describes the following three agreed methods for the determination of arsenic. The method of Schulek and v. Vilecz (*Z. anal. Chem.*, 1929, 76, 81) is applicable to most preparations. The more laborious Schneider distillation process, while of general application, is recommended especially for the determination of arsenic in preparations containing iron. The method of *P. Ned. Supp. I.* is recommended for use with derivatives of arspenamine.—*Bull. Féd. int. Pharm.*, 1938, 36.

Determination by a Continuous Electrolytic Method. A complete and detailed description is given of the apparatus and method of procedure which has been of considerable value in a food factory where a large number of arsenic tests are carried out.—H. C. Lockwood, *Analyst*, 1939, 657.

ORGANIC ARSENIC COMPOUNDS

Acetarsol (*B.P. Add. I*). $C_8H_{10}O_5NaAs = 275.0$. Contains 27.0 to 27.4% of As. Loss at 100° for 4 hours, not more than 0.5%; ash, not more than 0.2%. Assayed for arsenic by the method given for Tryparsamidum. Limit tests for inorganic arsenates and chlorides are included. The free amino-acid present, as indicated by the colour produced on diazotising, should not be greater than that produced by one-thousandth the quantity treated with the same reagents after boiling with hydrochloric acid and water and cooling. Acide *m*-acétylamino-*p*-hydroxyphénylarsinique, *Fr. Cx.* 1937, assayed for arsenic content by digestion with sodium hydroxide and sodium persulphate solution, addition of potassium iodide to the acidified mixture and titration with N/10 sodium thiosulphate, contains 27 to 27.5%. *m*-Acétylamino-*p*-hydroxyphénylarsinate de Sodium, *Fr. Cx.* 1937, assayed as for Chlorhydrate de Di-amino-di-hydroxy-arséno-benzène, contains 19 to 19.5% of arsenic.

Arsphenamina (*B.P.C.*). Complies with biological tests, carried out in an approved institution or laboratory, for maximum toxicity and therapeutic potency (*vide infra*) and contains, when determined by an approved method, from 30 to 34% of As. It is controlled by regulations made under the Therapeutic Substances Act, 1925, the standard preparation for Great Britain and Northern Ireland being kept in the National Institute for Medical Research, London. The percentage of As may be determined by the *B.P.C.* method for Sodii Aminarsonas. When kept in sealed phials at a temperature of 56° for twenty-four hours, it retains its colour, physical properties and solubility. It should comply with tests for solubility in water, a sodium hydroxide solution and a sodium chloride solution. Arsphenamina, *U.S.P. XII*,

complies with the requirements of the National Institute of Health, United States Public Health Service, and contains 30 to 32% of arsenic. Assayed by digesting for 10 minutes with five times its weight of powdered potassium permanganate and 25 volumes of diluted sulphuric acid and mixing well; a further 50 volumes of concentrated sulphuric acid is then added in small portions, the brown precipitate dissolved with just sufficient hydrogen peroxide, diluted and boiled to expel the excess; sufficient potassium permanganate is added to produce a pink coloration, this being decolorised with a drop of N/10 oxalic acid; the cooled solution is then set aside in the dark for 1 hour with potassium iodide when the liberated iodine is titrated with N/10 thiosulphate; a blank titration is made. All arsphenamine labels must bear an expiration date, which is not more than 5 years from the date of manufacture. 0.1 g. in 10 ml. of water requires 3.9 to 4.3 ml. of N/10 sodium hydroxide for neutralisation to phenolphthalein. The ampouled product shows no change in colour, consistency or solubility when kept at 70° for 48 hours. Dichlorhydrate de Diamino-di-hydroxy-arséno-benzène, *Fr. Cx.* 1937, contains not less than 30% of As and not more than 3% of S. Tests for toxicity on rabbits and mice are included.

Tests for Arsphenamine: Recognition in Medico-Legal Cases. The behaviour of arsphenamine with the usual reagents for arsenic has been investigated to find a method of distinguishing between it and inorganic arsenic in medico-legal cases.

Muscle from a patient who had died three weeks after injections of arsphenamine still gave reactions for arsenic. The drug gives the Reinsch, Marsh, Gutzeit (after oxidising and reducing) and biological tests for arsenic. The following serve to distinguish arsphenamine from inorganic forms of arsenic. With Bettendorf's reagent it gives an amorphous, yellow ppt. which dissolves on warming and reappears on cooling. H_2S gives no ppt. even after a solution of the drug has been boiled with HCl. The organic part of the arsphenamine molecule gives certain reactions, which may afford confirmatory evidence of the presence of the drug, thus:—The corresponding diazo-derivative gives a characteristic red to violet precipitate with α -naphthylamine, which may be isolated and examined for arsenic by the Reinsch or Gutzeit test. Sodium aminarsonate behaves similarly, giving a red azo-dye, but the diazotised arsphenamine gives no colour with β -naphthylamine, whilst sodium aminarsonate gives a vermilion-red azo colouring matter with the β -amine.

Minced horseflesh sprayed with arsphenamine solution and kept for 14 days was extracted with alcohol, slightly acidified with HCl. The residue so obtained gave positive results with the Reinsch, Gutzeit, and α -naphthylamine tests, but negative results with Bettendorf's reagent, and with hydrogen sulphide. So far it has proved impossible to obtain good results by applying to arsphenamine ordinary toxicological methods for the estimation of arsenic, the latter being obtained only to the extent of from 29 to 29.5% out of the 34% present.—*J. chem. Soc. Abstr.*, ii/1911, 448. See also Sir W. H. Willcox, *Brit. med. J.*, i/1916, 474.

Estimation of the arsenic excreted in the urine has been conducted, the general conclusions being: (a) the elimination begins rapidly; (b) the duration of the passing of arsenic in the urine is longer than was thought; (c) after subcutaneous injection the elimination is concluded more rapidly than by the intramuscular method; (d) simultaneous use of mercury caused delay in eliminating the arsenic; (e) potassium iodide given at the same time shortens the duration of the arsenic elimination.

Biological Tests.

Arsphenamine must be tested for toxicity and therapeutic activity. The Regulations under the Therapeutic Substances Act, 1925, do not give directions for these tests, but the directions are supplied on application to the Ministry

of Health. The directions describe the tests carried out in the National Institute for Medical Research, London.

(a) **Toxicity Test.** This is carried out on mice of uniform weight. 0.1 g. of arsphenamine is weighed and dissolved in about 6 ml. of water. The water is freshly distilled, being condensed and collected in glass vessels. 0.45 ml. of 2N sodium hydroxide is added, the liquid shaken and diluted to 10 ml. With this 1% solution five mice are injected with a dose corresponding to 0.1 mg. per g., and five mice with a dose of 0.125 mg. per g. The injections are made into the tail vein. The mice are observed during 3 days. The sample is regarded as not unduly toxic provided that at least three mice out of five have survived each dose.

(b) **Test for Therapeutic Potency.** The curative action of each sample is tested on mice infected with a species of trypanosome. *Trypanosoma equiperdum* is commonly used because it is non-pathogenic to man. This strain of trypanosome is carried for long periods in guinea-pigs and is transferred to rats by injecting some of the guinea-pigs' blood into the peritoneal cavity. When a test is to be carried out some thirty mice are infected from the blood of an infected rat. The trypanosomes in the rat's blood are counted and each mouse receives 0.5 ml. of a suspension containing a certain number of organisms. After 2 days the trypanosomes in the blood of each mouse are counted. The haemocytometer apparatus for counting red blood cells is used, the trypanosomes being stained with methyl violet. Those mice are used for the test which contain in their blood not less than 100,000 and not more than 500,000 trypanosomes per cu. mm. of blood. At least ten mice are then injected by way of the tail vein with the sample being tested, a dose of 0.01 mg. per g. being given; at least ten mice are also injected with the standard sample of arsphenamine in the same dose. The blood of the mice is then examined daily for the next four days to discover the rate of disappearance of trypanosomes. A sample is only accepted as satisfactory if its curative action is at least as quick as that of the standard and is seen in as large a proportion of mice.

Arsphenamina Argentica (B.P.C.). Controlled by regulations made under the Therapeutic Substances Act and complies with biological tests carried out in an institution or laboratory approved by the licensing authority for maximum toxicity and therapeutic potency (*vide infra*). By an approved method, such as that given under Sodii Aminarsonas, it contains not less than 18% and not more than 21% of As; it contains not less than 12% and not more than 13% of Ag, estimated by an approved method. The 5% aqueous solution should be almost black, and alkaline to litmus, and on the addition of sodium hydroxide or sodium carbonate no precipitate is produced, but with sodium bicarbonate a precipitate appears. It may be assayed for Ag by adding ammonium persulphate to an aqueous solution and boiling until colourless; diluting, adding nitric acid and titrating with N/50 ammonium thiocyanate to ferric ammonium sulphate indicator.

For the toxicity test, doses corresponding to 0.125 mg. and to 0.15 mg. per g. body weight are injected in 1% solution into the tail vein of each of five mice. Three mice must survive each dose. For the therapeutic test a 0.05% solution is injected into infected mice. Five receive 0.009 mg. per g. body weight and five receive 0.008 mg. The tests are performed as for arsphenamine.

Neoarsphenamina (B.P.). Controlled by regulations made under the Therapeutic Substances Act and complies with biological tests, carried out in an approved institution or laboratory, for maximum toxicity and therapeutic potency (*vide infra*). The standard preparation of neoarsphenamine is kept in the National

Institute for Medical Research, London. It complies with a test for solubility, and absence of arsphenamine. Kept in sealed phials for 24 hours at 56° it retains its colour, physical properties and solubility. Neoarsphenamina, *U.S.P. XII*, complies with the requirements of the United States Public Health Service and should contain not less than 19% of As, determined by the *U.S.P. XII* process for Arsphenamina. All neoarsphenamine labels must bear a date beyond which the substance must not be used, this date being not more than 3 years from the time of manufacture. Loss on drying for 24 hours in a vacuum desiccator over fresh phosphorous pentoxide, not more than 1.5%. The *Fr. Cx.* 1937 requires the substance to comply with toxicity tests, to contain not less than 19% of arsenic and not more than 12% of sulphur.

Biological Tests.

Neoarsphenamine is tested for toxicity and potency by tests similar to those given for arsphenamine.

(a) **Toxicity test.** An important study of the toxicity of neoarsphenamine has been published by Durham, Gaddum and Marchal (*Spec. Rep. Ser. med. Res. Coun., Lond.*, No. 128, 1929). They determined the curve relating the percentage of mice killed to the dose injected, obtaining a curve for mice of 14 g. and also for mice of 19 g. The dose of the international standard neoarsphenamine which kills 50% of mice of 14 g. weight is 8.1 mg. By international agreement samples are allowed to pass the test if they do not exceed the toxicity of the standard by more than 20%, hence it would be expected that the dose of a sample to be

injected would be $\frac{5}{6} \times 8.1$ or 6.75 mg. Actually the requirement in Gt. Britain is more lenient than this, for the dose to be injected is only 6 mg., from which it follows that samples exceeding the toxicity of the standard by 35% are accepted. Apparently no country imposes a more severe standard than this despite the international agreement to do so. The test requires a dose of 6 mg. in 2% solution to kill not more than 15 out of 30 mice of 13 to 15 g. weight. Experience has shown that some samples which pass this test are more toxic when injected in stronger solution, and therefore a subsidiary test in which a 5% solution is used is also performed. A dose equivalent to 0.225 mg. per g. is injected into five rats, of which not more than one may die if the sample is to be approved.

(b) **Therapeutic test.** The test is similar to that for arsphenamine. Five infected mice receive 0.03 mg. per g. as a 0.2% solution, and 5 mice receive 0.025 mg. per g. Similar doses of the standard are also given to the same number of other mice.

Variations in Toxicity and Trypanocidal and Spirochæticidal Properties. 18 samples, prepared by 7 different laboratories, of neoarsphenamine purchased on the open market were found to vary considerably. The maximum tolerated dose for white rats varied from 0.200 g. to 0.300 g. per kilo of weight; the average minimal trypanocidal dose varied from 0.004 to 0.008 g. per kilo weight, 28% being incompletely trypanocidal; and with the average minimal spirochæticidal dose for rabbits with acute syphilitic orchitis of 0.020 g. per kilo, 14 samples were completely spirochæticidal in this dose while 6 were not. The establishment of standards urged.—J. F. Schomberg and J. A. Kolmer, *J. Amer. med. Ass.*, i/1933, 183.

Neoarsphenamine having a low toxicity need not have a low trypanocidal activity. Most of a number of brands assayed, which showed a low toxicity had a high trypanocidal potency, and the most toxic were usually, although not invariably, the least active.—C. A. Morrell and M. G. Allmark, *J. Amer. pharm. Ass., Sci. Edn.*, 1941, 33.

Sulpharsphenamina (B.P. Add. I). Controlled by the regulations made under the Therapeutic Substances Act, 1925. The standard preparation is kept in the National Institute for

Medical Research, London. It complies with biological tests, carried out in an institution or laboratory approved by the licensing authority, for maximum toxicity and therapeutic potency (*vide infra*). It should comply with a test for absence of arsphenamine, and should retain its colour, physical properties and solubility when kept in sealed phials at 56° for 24 hours. The test for distinction from neoarsphenamine requires no precipitate to be produced on the addition of dilute hydrochloric acid to an equal volume of solution of the substance (1 in 3). The sterile solution should be used immediately after preparation. Sulpharsphenamina, *U.S.P. XII*, contains not less than 19% of As, when assayed by the *U.S.P. XII* method for Arsphenamina. 0.6 g. dissolves completely in 3 ml. of distilled water within 5 minutes. The label on the container complies with the regulations given under arsphenamine and there is a similar test for the ampouled product. The substance of the *Fr. Cx.* 1937 should contain 18 to 20% of arsenic, not more than 15% of sulphur and complies with toxicity tests and tests for trypanocidal power.

The biological tests for sulpharsphenamine are similar to those for neoarsphenamine except that the doses are given by subcutaneous injection. For the toxicity test on mice, the volume injected into each mouse of 14 g. is 0.35 ml. of a 2% solution; for the subsidiary test on rats each rat receives 0.35 mg. per g. in 10% solution. For the therapeutic test, five mice receive 0.05 mg. per g. and five mice receive 0.04 mg. per g., both given as a 0.2% solution.

Sodii Aminarsonas (B.P.C.). $C_6H_7O_3NaAsNa = 239.0$. Contains from 24 to 25.6% of As, when assayed by the method of the *B.P.C.* '34: 0.2 g., accurately weighed, is heated for 1 hour with 5.5 ml. of sulphuric acid and 1 ml. of fuming nitric acid; to the slightly cooled product 15 drops of fuming nitric acid are added and heat applied for a further 5 minutes; 1 g. of ammonium sulphate is cautiously added and after cessation of evolution of nitrogen, cooling, and diluting to about 70 ml., 1 g. of potassium iodide is added and the liquid concentrated to about 40 ml.; after decolorisation with just sufficient N/100 sodium thiosulphate and dilution to about 110 ml., the addition of 50 ml. of 4N sodium carbonate and a slight excess of sodium bicarbonate, for neutralisation, the mixture is titrated with N/10 iodine, using starch mucilage as indicator. Anilarsinate de Sodium, *Fr. Cx.* 1937, the substance with 4 molecules of water, contains not less than 24% of arsenic.

Sodii Cacodylas (B.P.C.). $C_2H_6O_2AsNa_3 \cdot 3H_2O = 214.0$. By the *B.P.C.* method for Sodii Aminarsonas it contains from 72 to 75% of $C_2H_6O_2AsNa$. It complies with limits for acidity or alkalinity to phenolphthalein, disodium methyl arsonate, arsenate and phosphate. The *U.S.P. XII* allows the same limits of purity; assayed by digestion with sulphuric acid and potassium sulphate, cooling and neutralising the solution, rendering faintly acid and titrating with N/10 iodine. Cacodylate de Sodium, *Fr. Cx.* 1937, assayed similarly, contains 73 to 76% of the anhydrous salt; it is also assayed for arsenic by the method given under Arsphenamina. Méthylarsinate de Sodium, *Fr. Cx.* 1937,

contains not less than 25.5% of arsenic. Natrium kakodylicum, *P.G. VI*, $(\text{CH}_3)_2\text{AsO}_2\text{Na} + 3\text{H}_2\text{O}$, contains 32.8 to 35% of arsenic; assayed by addition of 5 ml. of water, 10 ml. of sulphuric acid and 2.5 g. of potassium permanganate to 0.2 g. of substance, strongly shaking and allowing to stand for 20 hours; then after warming on a water-bath at 100° and then on a wire gauze for 12 to 20 minutes, cooling, rinsing the flask with 50 ml. of water and decolorising with crystals of oxalic acid, finally adding 2 g. of potassium iodide and titrating with N/10 sodium thiosulphate. 1 ml. of N/10 sodium thiosulphate = 0.003748 g. of arsenic. Natrium cacodylicum, *P. Helv. V*, by digestion with sulphuric acid and potassium sulphate, diluting and titrating, after addition of hydrochloric acid and methyl orange, with N/10 bromide-bromate solution until the red colour disappears, contains 72 to 75% of the anhydrous substance, equivalent to 0.003748 g. of arsenic. 1 ml. of N/10 KBrO_3 = 0.00800 g. of $\text{C}_2\text{H}_5\text{O}_2\text{AsNa}$ = 0.003748 g. of As.

Tryparsamidum (*B.P. Add. I*). $\text{C}_8\text{H}_{10}\text{O}_4\text{N}_2\text{AsNa}_2 \cdot \frac{1}{2}\text{H}_2\text{O}$ = 305.0. Loses at 110° from 2.5 to 3.5% of its weight and then contains 25.1 to 25.5% of As in organic combination, and 9.25 to 9.5% of N. Assayed for nitrogen by the Kjeldahl process and for As by digestion with sulphuric and fuming nitric acids followed by addition of ammonium sulphate; to the cooled and diluted colourless liquid potassium iodide is added, the solution concentrated and decolorised with N/10 sodium thiosulphate; after rendering alkaline and then acid, sodium bicarbonate is added and the As titrated with standard iodine. Contains not more than 0.25% of arsanilic acid, as shown by comparing the colour produced on diazotising a quantity with addition of arsanilic acid, with that from one half the quantity of substance with twice the amount of added arsanilic acid. Tests for absence of arspenamine compounds, and of arsenate and phosphate are included. The 30% solution should remain clear for 6 hours. The *U.S.P. XII* substance, assayed similarly, is required to comply with the same standard for As. All tryparsamide labels must bear an expiration date, which is not more than 5 years after the date of manufacture. By treatment of 0.5 g. in 45 ml. water with hydrochloric acid and potassium iodide on the water-bath for 20 minutes and, after cooling and addition of excess sodium bicarbonate, titration with N/10 sodium thiosulphate, the *Fr. Cx.* 1937 substance contains 24.4 to 24.9% As.

Test for Arsanilic Acid. Estimation of small amounts of arsanilic acid in tryparsamide can be carried out by the following colorimetric method. Weigh accurately 0.5 g. and 1.0 g. of tryparsamide into two test-tubes and dissolve in 6 ml. of distilled water. Cool each tube below 5° in an ice-bath and add 2.5 ml. of 4% sodium nitrite solution followed by 5 ml. of dilute hydrochloric acid. The solutions are mixed after each addition of reagent. Pour the contents of each tube into 10 ml. of a previously cooled solution of β -naphthol. Mix the diazotised solution and alkaline β -naphthol by pouring from one tube to the other and place in the 1 cm. cell of a Lovibond Tintometer. Match the colour and record the red units. The quantity of arsanilic acid present is determined by reference to the graph included in the paper. The weights of sample taken give a colour of an order to be easily matched, provided

that the sample just satisfies the *B.P.* limit test for arsanilic acid of which the method described is a modification. The critical factor in the estimation is the amount of sodium nitrite and most accurate results are obtained when an amount of tryparsamide containing arsanilic acid sufficient to give a colour between 4.0 and 8.0 red units is used. The Pharmacopœial limit test is satisfactory for tryparsamide containing mere traces of arsanilic acid, but where larger amounts are present it is not possible to determine whether the sample satisfies the test or not.—C. A. MacDonald and J. G. Reynold, *Quart. J. Pharm.*, 1939, 534.

Trypanocidal action and chemical constitution of arsenic compounds.—H. King, W. O. Murch and I. E. Balaban, *J. chem. Soc.*, 1925, 2632, 2701.

ASAFŒTIDA

Asafœtida (*B.P.*). Leaves not more than 50% of matter insoluble on boiling with alcohol (90%) and drying at 100°. Ash, not more than 15%. **Asafœtida**, *N.F. VII*, by continuous extraction with alcohol (94.9%), drying the residue at 100° for 30 minutes and calculating to the dried drug (the moisture having been determined by toluene distillation) yields not less than 50% of extractive; acid-insoluble ash, not more than 15%.

Asafetida Oil has been examined; the main fraction, b.p. 82° to 84° at 10 mm., is optically active, has a composition corresponding to $C_7H_{14}S_2$ and structural formula $CH_3CH_2 \begin{matrix} \searrow \\ CH \cdot S \cdot S \cdot CH : CH \cdot CH_3 \end{matrix}$.—Mannich and Fren-

senius, *Arch. Pharm., Berl.*, 1936, 461, per *Quart. J. Pharm.*, 1936, 710.

Myrrha (*B.P.*). Contains not more than 4% of other organic matter; ash, not more than 9%; matter insoluble in alcohol (90%), not more than 70%. **Myrrha**, *U.S.P. XII*, yields not less than 30% of alcohol-soluble extractive; acid-insoluble ash, not more than 5%.

AZORUBRUM

(and OTHER MEDICINAL DYES)

Azorubrum (*B.P.C. Supp. IV*). $C_{20}H_{12}N_2O_7S_2Na_2 = 502.2$. (Bordeaux B—Colour Index No. 88). Contains 60 to 70% of $C_{20}H_{12}O_7N_2S_2Na_2$. Assayed by the *B.P.* method described for Methylthioninæ Chloridum, dissolving in hot water and continuing the titration with N/10 titanous chloride until the solution is nearly colourless. 1 ml. N/10 titanous chloride = 0.001255 g. of $C_{20}H_{12}O_7N_2S_2Na_2$. Limit of zinc; 0.1 g. ignited with sulphuric acid and the residue dissolved in 2 ml. dilute hydrochloric acid and 10 ml. water, dilute solution of ammonia added, boiled and filtered, on acidifying and adding 1 ml. of potassium ferrocyanide solution, produces not more than a faint turbidity. Bordeaux B is practically unaffected by dilute acids or alkalis or by exposure to sunlight, but in use it must not be confused with other dyes known by the same name.

Magenta (*B.P.C.*). (Colour Index No. 677). The sulphated ash is not more than 5% and that from 1 g. gives no precipitate of zinc ferrocyanide. This is basic fuchsine and should be distinguished from acid fuchsine (Colour Index No. 692).

Carminum (B.P.C.). Loses not more than 15% of its weight at 100°, and then yields not more than 10% of ash. A limit of insoluble matter is included. The *N.F. VII* allows 25% loss on drying at 100°; ash, not more than 12%; tests for tin, lead, and soluble barium compounds and for insoluble salts are included.

Methylthioninæ Chloridum (B.P.). $C_{16}H_{18}N_3ClS = 319.7$. Methylene blue is assayed by titration in boiling aqueous solution acidified with hydrochloric acid, the air in the flask being replaced by carbon dioxide, with N/10 titanous chloride until the blue colour is replaced by a reddish-grey; 1 ml. of N/10 titanous chloride is equivalent to 0.01598 g. of $C_{16}H_{18}N_3ClS$, and a purity of not less than 80% is indicated. The solution on reduction is decolorised with potassium iodide, it produces a deep blue flocculent precipitate, with a pale blue supernatant liquid, and, on oxidation with potassium dichromate, gives a reddish-violet colour and a bluish-violet precipitate, the blue colour being restored with sulphurous acid. A limit of zinc is included. Methylthioninæ Chloridum, *U.S.P. XII*, is the trihydrate ($C_{16}H_{18}N_3ClS \cdot 3H_2O$) and loses not more than 18% at 110°; ash, not more than 1.2%; the dried salt contains 98.5% of the pure anhydrous substance. In the revised assay process a cooled solution of the substance is precipitated with potassium perchlorate solution, the residue filtered and washed with saturated methylthionine perchlorate solution, and dried at 110°.

In the absence of B.P. limits for moisture and ash, 20% of the material may be neither water nor methylene blue.—*Pharm. J.*, ii/1932, 128.

An official quantitative method for the determination of methylthionine chloride in tablets and capsules is described in *Methods of Analysis* (A.O.A.C., 1940). Clean, if necessary, a solution of the material containing about 0.1 g. to 0.14 g. of methylene blue with carbon tetrachloride or with dichlorhydrin, shake well with 50 ml. of glacial acetic acid and allow to stand for 25 minutes. Add 30 ml. of N/5 iodine, at first about one-third by fast drops and the remainder quickly, shake and allow to stand for 50 mins., shaking occasionally. Adjust to 200 ml., stand for a further 10 minutes, filter rapidly and then titrate an aliquot portion of the filtrate with N/10 thiosulphate and make a blank determination; 1 ml. of N/5 iodine = 0.01495 g. of methylene blue.

For the use of methylene blue as a renal function test, see p. 663.

Methylrosanilinæ Chloridum (U.S.P. XII). Loses not more than 7.5% at 110°; ash, not more than 1.5%; limit of dextrin, 1%. A limit of lead is prescribed.

Methylviola (B.P.C.). (Colour Index No. 680). Methyl violet yields not more than 5% of sulphated ash, of which that from 1 g. gives no precipitate of zinc ferrocyanide in presence of hydrochloric acid. Limit of dextrin insoluble in boiling alcohol, not more than 1%.

Novaurantia (B.P.C.). $C_{14}H_{10}N_2O_7S_2Na_3 = 452.2$. (Colour Index No. 27). Orange G yields not less than 36% and not more than 50% of sulphated ash. The sulphated ash from 1 g. gives no precipitate of zinc ferrocyanide.

Phenothiazina (N.F. VII). $C_{15}H_9NS = 199.26$. When dried at 100°, loses not more than 0.5% and contains not less than 95% $C_{15}H_9NS$. Phenothiazine melts between 181° and 185° and is assayed colorimetrically after oxidation with bromine, by comparison against a test solution of phenothiazine melting between 184° and 185°.

Rubrum Scarlatinum (B.P.C.). (Colour Index No. 258). Scarlet red yields not more than 10% of sulphated ash. Rubrum Scarlatinum, *N.F. VII*, yields not more than 1% of ash and not more than 1% of water-soluble substances dried at 100°.

Tartrazina (B.P.C.). $C_{16}H_8O_5N_4S_2Na_2 = 534.2$. (Colour Index No. 640). Leaves not more than 80% of sulphated ash, which complies with the limit test for zinc.

Viola Crystallina (B.P.C.). (Colour Index No. 681). Crystal violet yields not more than 5% of sulphated ash, which should comply with the limit test for zinc.

Distinction from Methyl Violet. 2 ml. of a 0.1% aqueous solution of the dye is treated with 8 ml. of alcohol and 5 ml. of sodium hydroxide solution; after standing for 2 minutes the solution should be clear and colourless.—F. Reimers, *Dansk. Tidsskr. Farm.*, 1937, 52.

Viride Malachitum (B.P.C.). (Colour Index No. 657). Malachite green yields not more than 1% of sulphated ash, which should comply with the limit test for zinc.

Viride Nitens (B.P.C.). (Colour Index No. 662). $C_{27}H_{22}N_4SO_4H = 482.3$. Brilliant green yields not more than 5% of sulphated ash which complies with the limit test for zinc.

Indicarminum (B.P.). $C_{16}H_8O_8N_2S_2Na_2 = 466.2$. Indigo carmine is assayed by titration with N/10 potassium permanganate in warm solution acidified with an equal volume of dilute sulphuric acid, the colour changing from green to pale yellow; each ml. of N/10 potassium permanganate is equivalent to 0.0133 g. of $C_{16}H_8O_8N_2S_2Na_2$ of which not less than 90% should be indicated, calculated on the substance dried at 100°. Loss at 100°, not more than 10%, and the residue on ignition and re-ignition with sulphuric acid is then not less than 30% and not more than 40%. The *Fr. Cx.* 1937 assays by treatment with nitric acid and ignition and requires the residue (mostly sodium sulphate) to be 33 to 38%.

For the use of indigo carmine as a renal function test see p. 663.

Indigo or Indigotin (natural) is obtained from the shoots of *Indigofera tinctoria* (Leguminosæ) in India and Java, by maceration with lime and water. The pure substance has the composition $C_{16}H_{10}N_2O_2$.

Indigo Soluble, as mostly understood, is the acid substance, not the sodium salt.

Isatin. $C_8H_5NO_2$. Yellowish-red prismatic crystals obtainable by oxidising indigo with chromic or nitric acid, also by boiling *o*-nitrophenylpropionic acid with caustic soda.

Litmus is a blue pigment obtained from *Rocella tinctoria* (Discomycetes). Employed chiefly as an indicator for acid and alkali as Litmus Paper, also in form of solution in volumetric analysis. Litmus is made in Holland by fermenting lichens in presence of ammoniacal liquids and potash.

LITMUS SOLUTION (see Indicators, p. 606).

In titration, all CO_2 must be removed by boiling before taking end reaction. Not suitable for weak bases. Quinine, morphine and strychnine are neutral to it and the acids in their salts can be titrated as if base were absent.

Carbon dioxide only turns litmus "wine red" when alkaline bicarbonates are present as impurities, otherwise it turns it red just like any other acid.

Lacmoid, also known as Resorcin Blue, is chiefly diazo-resorcin. Solution (0.2% in dilute alcohol), employed as indicator, closely resembles litmus in reactions.

Cudbear, syn. Red Indigo, a purplish-red powder obtained by the ammoniacal fermentation of *Lecanora tartarea* and other lichens, designated in Germany *Persio*, in France *Orseille de terre*. Except for the fact that it is in the condition of a fine powder it is virtually the same as orchil. *Persio, N.F. VII*, yields not more than 12% of total ash; the depth of colour of the alcohol- and water-soluble matter from 0.005 g. approximates that of 1.5 ml. of 5.95% cobaltous chloride solution in hydrochloric acid and water with 3 ml. of N/200 potassium dichromate and 30 ml. of ammonium carbonate solution.

Archil, syn. Orchil. The word Archil, or more properly Orchil, was originally the name of the plant from which the dye, which goes under this name, is obtained. It appears that before the introduction of orchil into this country a similar dye obtained from certain lichens in Scotland was in use under the name "Cork." This is given in Miller's "Plant Names" as the name of the lichens yielding archil.

Turnsole, syn. Tournesol (French). The familiar colouring used on Dutch cheeses. The word has been more particularly applied to a product from *Chrozophora tinctoria* A. Juss (*Croton tinctorius* Linn.)—a native of Southern Europe and the Orient. Rags soaked in the juice of this plant are exported to Holland. They change colour on exposure to ammonia vapour, and this purple colour can be extracted with water for the purpose in question. Turnsole was at one time supposed to form the colouring matter of litmus.

BALSAMUM PERUVIANUM

Balsamum Peruvianum (B.P.). Balsamic esters, determined by extraction with ether in alkaline solution, evaporation and drying at 100° for 30 minutes, not less than 53% and having a saponification value of not less than 235. Balsamum Peruvianum, *U.S.P. XII*, by a similar but aliquot part method, yields 50 to 60% by weight of cinnamein, having a saponification value of 230 to 240; acid number, 56 to 84. Baume de Pérou, *Fr. Cx.* 1937, contains 52 to 56% of cinnamein.

Various qualitative tests for the detection of adulteration are described.—E. M. Smelt, *Quart. J. Pharm.*, 1932, 378.

The greater part of the alcohol peruvial which was considered to be a constituent has been shown to consist of nerolidol, a sesquiterpene alcohol $C_{15}H_{24}O$, also present in oil of neroli.—*Mnfg. Chem.*, 1940, 244.

Balsamum Tolutanum (B.P.). Free balsamic acid content, 19 to 25%, and total balsamic acid content, 35 to 50%, both calculated with reference to the dried alcohol-soluble matter. Assayed by precipitation, for free balsamic acids in an alcoholic potash solution and total balsamic acids in a saponified solution, with magnesium sulphate, filtration and extraction of the acidified filtrate with ether, transferring to sodium bicarbonate solution, re-extraction with ether and drying in a vacuum desiccator over sulphuric acid. Acid value, by a specified process, 97 to 160; ester value, 47 to 95; saponification value, 170 to 224—all calculated on the dry alcohol-soluble matter. Matter insoluble in alcohol, not more than 4%. Loss *in vacuo* over sulphuric acid, not more than 4%. The *U.S.P. XII* substance has an acid number of 112 to 168 and a saponification value of 154 to 220.

Benzoinum (B.P.). Sumatra benzoin only is official. The dry alcohol-soluble matter yields from 19 to 29% of free balsamic acids, and 30 to 60% of total balsamic acids, and has an acid value of 115 to 163, an ester value of 47 to 83, and a saponification value of 169 to 223. Alcohol-insoluble residue, dried at 100°, not more than 20%. Loss *in vacuo* over sulphuric acid, not more than 10%. Ash, not more than 2%. The *U.S.P. XII* requires Sumatra benzoin to yield 75% of alcohol-soluble extractive and not more than 1% of acid-insoluble ash, and Siam benzoin, not more than

1% of foreign organic matter, 90% of extractive, and not more than 0.5% of acid-insoluble ash. Alcohol-soluble extractive determined by continuous extraction for 5 hours, with the addition of sodium hydroxide to the receiving flask, weighing the insoluble residue and subtracting this plus the moisture determined by toluene distillation from the original weight taken; the *U.S.P. XII* deletes the test for rosin included in the *U.S.P. XI*.

The *B.P.* ash limit is too stringent and the acid and ester values will exclude many genuine samples.—E. J. Parry, *Chem. & Drugg.*, ii/1932, 251.

Styrax (*B.P.*). Loses in one hour on a water-bath not more than 5% of its weight and then contains not less than 30% of total balsamic acids, has an acid value of 55 to 90, an ester value of 100 to 133, and a saponification value of 170 to 200. Assayed by the process for total balsamic esters as given under *Balsamum Tolutanum*. *Styrax, U.S.P. XII*, is not the purified product and both the Levant and American varieties are official. After purification it has an acid value of 50 to 85 (Levant storax) or 36 to 85 (American storax), a saponification value of 160 to 200, and yields not less than 25% of cinnamic acid; determined by saponification and evaporation of the neutralised liquid, followed by cleaning of the dissolved residue with ether, acidifying and extracting with ether; after evaporating the ether, the residue is refluxed with boiling water, the hot filtered solution cooled to 25°, the separated cinnamic acid collected on a Gooch, and dried at 80°.

BARBITONUM

Barbitonum (*B.P.*). $C_8H_{12}O_3N_2 = 184.1$. M.p., 189° to 192°. Ash not more than 0.05%. Neutral and basic substances, not more than 0.1%. *Barbitalum, U.S.P. XII*, yields not more than 0.1% of ash; m.p., 188° to 192°.

Tabellæ Barbitali (*U.S.P. XII*). Contain 94 to 106% of the labelled amount of $C_8H_{12}N_2O_3$, including all tolerances. Assayed by dissolving a weighed quantity of powdered tablets in an aqueous solution of sodium hydroxide (1 in 50) saturated with sodium chloride, extracting with ether and rejecting the ether extracts, then acidifying with hydrochloric acid and extracting the barbitone with alcohol-ether-chloroform mixture (2:1:7). The extracts are washed with faintly acid water and the aqueous washings are extracted with ether. After filtration of the combined solvent and ether extracts, the organic solvents are removed, the residue dried at 100° for 2 hours and weighed.

An official quantitative method for the determination of barbitone or phenobarbitone in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 574)*.

Barbitonum Solubile (*B.P.*). $C_8H_{11}O_3N_2Na = 206.1$. Yields, by extraction with ether from acidified solution and drying at 100°, barbitone equivalent to not less than 97% of the pure sodium salt. The *U.S.P. XII* requires *Barbitalum Sodicum* to lose not more than 1% at 100°. Yields 88 to 90% barbitone, calculated on a moisture-free basis. *Barbitalum solubile, P. Helv. V*, by titration in aqueous solution to methyl orange with N/10 hydrochloric acid, contains not less than 97% of $C_8H_{11}O_3N_2Na$.

Tabellæ Barbitali Sodici (U.S.P. XII). Contain 94 to 106% of the labelled amount of $C_5H_4N_2O_3Na$, including all tolerances. Assayed by the process described for barbitone tablets.

Hexobarbitonum (B.P. Add. III). $C_{12}H_{16}O_3N_2 = 236.1$. M.p., 145° to 147° . Neutral and basic substances, not more than 0.1%. Ash, not more than 0.05%.

Hexobarbitonum Solubile (B.P. Add. III). $C_{12}H_{15}O_3N_2Na = 258.1$. Contains, by titration with N/10 sulphuric acid to methyl red, a percentage of sodium equivalent to 8.86 to 9.0% of the $C_{12}H_{15}O_3N_2Na$; yields by extraction with chloroform from the acidified liquid from the sodium titration, and drying at 100° , hexobarbitone equivalent to not less than 96% of the pure substance. Neutral and basic substances, not more than 0.1%.

Pentobarbitalum Sodicum (U.S.P. XII). $C_{11}H_{17}O_3N_2Na = 248.15$. Calculated on the anhydrous substance, it contains 90 to 92% of pentobarbital ($C_{11}H_{18}O_3N_2$). Loses not more than 5% during 6 hours at 90° . Assayed by extraction with ether from acidified solution, finally drying at 90° .

Tabellæ Pentobarbitali Sodici (U.S.P. XII). Contain 90 to 105% of the labelled amount of $C_{11}H_{17}O_3N_2Na$, including all tolerances. In the assay, a weighed quantity of the powder obtained from not less than 20 tablets is dissolved in 2% aqueous sodium hydroxide solution saturated with sodium chloride. After preliminary extraction with ether, the solution is acidified with hydrochloric acid and extracted completely with alcohol-ether-chloroform mixture (2:1:7). The combined extracts are washed with faintly acid water, filtered, evaporated on a steam-bath and the residue is dried at 100° and weighed.

Phenobarbitonum (B.P.). $C_{12}H_{12}O_3N_2 = 232.1$. M.p., 173° to 177° . Ash, not more than 0.05%. Phenobarbitalum, U.S.P. XII, yields not more than 0.15% ash.

Tabellæ Phenobarbitali (U.S.P. XII). Contain 94 to 106% of the labelled amount of $C_{12}H_{12}O_3N_2$, including all tolerances. In the assay, a weighed quantity of powdered tablets is shaken for 10 minutes with a reagent prepared by saturating a saturated solution of sodium chloride with barium hydroxide. After filtration, an aliquot of the filtrate is acidified with hydrochloric acid and extracted completely with chloroform-ether mixture (8:2). The combined extracts are washed with faintly acid water and the aqueous washings extracted with two further portions of solvent which are added to the main extract. The chloroform-ether solution is then filtered, the organic solvent removed, and the residue dried at 100° for 2 hours.

Phenobarbitonum Solubile (B.P.). $C_{12}H_{11}O_3N_2Na = 254.1$. Contains not less than 95% of the pure substance. Phenobarbitalum Sodicum, U.S.P. XII, on drying at 140° for 6 hours, loses not more than 7%. Contains 89 to 91.5% of phenobarbital, calculated on a moisture-free basis.

Tabellæ Phenobarbitali Sodici (U.S.P. XII). Contain 90 to 105% of the labelled amount of $C_{12}H_{11}O_3N_2Na$, including all tolerances. Assayed by the process described for phenobarbitone tablets.

Allobarbitonum (B.P.C.). $C_{10}H_{12}O_3N_2 = 208.1$. M.p., 171° to 172° . Ash, not more than 0.1%.

Phemitonum (B.P. Add. III). $C_{13}H_{14}O_3N_2 = 246.1$. M.p., 178° to 181° . Limit of neutral and basic substances, 0.25%.

Phenytoinum Solubile (B.P.C. Supp. III). $C_{15}H_{11}O_2N_2Na=274.1$. Assayed by direct titration of an alcoholic solution against N/10 hydrochloric acid, it contains not less than 98% of $C_{15}H_{11}O_2N_2Na$. Loss at 100° , not more than 1%. Diphenylhydantoin Sodicum, *U.S.P. XII*, loses not more than 2.5% at 100° and then contains 90.5 to 92% of $C_{15}H_{11}O_2N_2$. Assayed by extraction with ether from an acid solution, removal of the ether and weighing the base, dried to constant weight at 100° .

Identification of Barbiturates. A solution of 0.05 g. of the substance in 4 ml. of acetone is treated with 5 drops of Millon's reagent. A white precipitate dissolving on warming for 4 to 6 seconds then re-precipitated after a further 12 to 16 seconds warming indicates barbitone; a precipitate insoluble but becoming grey on warming for 10 to 15 seconds indicates allobarbitone. A white turbidity increasing on heating and shaking but dissolving with the simultaneous appearance of a slate-grey coloration after 15 to 25 seconds indicates phenylethyl-N-methylbarbituric acid (Prominal); solution of the white precipitate after heating for 8 to 10 seconds and appearance of a slate-grey precipitate after about a further 11 seconds indicates methylphenylbarbituric acid (Rutonal). A turbidity dissolving on shaking and warming with formation of a slate-grey precipitate in 20 to 30 seconds indicates Evipan. If no precipitate is formed with Millon's reagent and the acetone solution 0.05 g. of the substance is dissolved in 4 ml. of 95% alcohol and 5 drops of the reagent added. A yellowish-white precipitate becoming yellow on warming and white on the addition of 1 drop of hydrochloric acid, insoluble in 10 ml. of cold hydrochloric acid but soluble on warming indicates Evipan. A white precipitate insoluble on shaking or warming but soluble in 10 ml. of hot hydrochloric acid indicates phenobarbitone. A white turbidity insoluble on shaking or heating and giving a precipitate with 1 drop of hydrochloric acid but dissolving in 10 ml. of hot acid giving an amber-coloured solution indicates Phanodorm. A white turbidity soluble on warming and reacting with hydrochloric acid as Phanodorm but giving a colourless solution indicates butylethylbarbituric acid (Soneryl). No turbidity in the cold or on heating, but formation of a precipitate with 1 drop of hydrochloric acid, the precipitate dissolving with more acid indicates etho-2-butylethylbarbituric acid (Narcosol).—M. Paget and Tilly, *J. Pharm. Chim., Paris*, i/1937, 222.

Dissolve in concentrated sulphuric acid, add a few drops of formaldehyde solution and warm on a water-bath. Dial shows intense red colour with green fluorescence, Numal and Sandoptal give same reaction. Luminal, Rectoral, and Prominal give same red colour. Phanodorm gives yellow to orange. Veronal, Proponal, Soneryl, and Amytal give no reaction. If the formaldehyde is replaced by *p*-dimethylamino-benzaldehyde, Dial gives, on warming, a currant red colour, and addition of a few drops of water causes a change to reddish-violet. This is specific to Dial.—M. M. Pesetz, *J. Pharm. Chim., Paris*, 1938, 27, 247.

Methods of identification are given for barbiturates in solids, liquids, urine, blood and viscera.—M. M. Pesetz, *J. Pharm. Chim., Paris*, 1938, 28, 69.

Figures are given for the melting-points of numerous substituted barbituric acids together with their xanthidrol and *p*-nitrobenzyl derivatives.—J. C. Jespersen and K. T. Larsen, *Arch. Pharm., Berl.*, 1937, 28, per *Quart. J. Pharm.*, 1937, 544.

Determination of Phenobarbitone and Theobromine in Mixtures. The phenobarbitone is extracted from the mixture with alcohol-free ether. The residue of theobromine is boiled with dilute sulphuric acid, the solution cooled, made alkaline to phenol red with sodium hydroxide and then sulphuric acid carefully added until the solution is neutral. Then silver nitrate solution is added and the liberated nitric acid titrated with sodium hydroxide solution. The phenobarbitone is determined by extraction with alcohol-free ether, removing the ether, dissolving the residue in a mixture of alcohol water and sodium hydroxide, filtering and titrating an aliquot portion with silver nitrate solution. The method is applicable to tablets, providing stearates are absent. When the theobromine is present as salts, the method is slightly modified.—C. W. Bell, *J. Amer. pharm. Ass., Sci. Edn.*, 1941, 240.

Microchemical Detection of Barbituric Acid Compounds. The reactions of the following barbituric acid compounds are described in tabular form, and illustrated by drawings of the various types of crystals formed: Veronal (diethylbarbituric acid, m.p. 191°), Proponal (dipropylbarbituric acid, m.p. 145°), Dial (diallylbarbituric acid, m.p. 170° to 171°), Allonal (allylisopropylbarbituric acid, m.p. 141·5°), Soneryl (butylethylbarbituric acid, m.p. 123°), Luminal (phenylethylbarbituric acid, m.p. 174° to 176°), Rutonal (phenylmethylbarbituric acid, m.p. 226° to 228°), phanodorm (cyclohexenylethylbarbituric acid, m.p. 173°), and Sandoptal (isobutylallylbarbituric acid, m.p. 136° to 139°). When the 2% solutions of the compounds in potassium hydroxide are precipitated with nitric acid, Proponal, Dial, Luminal and Rutonal form well-defined crystals at once, but Veronal, Allonal, Soneryl, Phanodorm and Sandoptal give a finely divided amorphous precipitate, slowly becoming crystalline. On adding ammonium phosphate or other ammonium salt to the 2% solutions in potassium hydroxide, Veronal, Proponal, Dial, Luminal, Rutonal and Sandoptal give at once well-formed cubic and rhombic crystals, whilst after some time, Allonal, Soneryl and Phanodorm form crystals belonging to the binary system.

Reaction with thallium acetate. When the 2% potassium hydroxide solutions are treated with thallium acetate, only Veronal, Proponal, Allonal and Phanodorm give crystalline compounds. **Reaction with silver nitrate.** When the compounds are treated with 5% ammoniacal silver nitrate all but Veronal and Dial give soluble silver compounds. **Reaction with ammoniacal cuprous solution.** To the 2% potassium hydroxide solutions copper acetate is added and enough ammonia to dissolve the hydroxide precipitated. The reaction goes even better when Schweitzer's reagent is used instead. The copper ammonia compounds are all soluble except those of Dial, Rutonal and Sandoptal, which give amethyst-coloured crystals. **Reaction with bromine water.** All the compounds except Veronal give an amorphous precipitate with bromine water from the 2% solution in potassium hydroxide; with Proponal, Luminal, Rutonal and Phanodorm this slowly becomes crystalline. **Reaction with baryta water.** Only Dial gives crystals. From the above reactions it is possible to identify any of the given barbituric acid compounds.—L. van Itallie and A. J. Steenhauer, *Pharm. Weekbl.*, 1930, 977.

BARIUM

Barii Sulphas (B.P.). $\text{BaSO}_4 = 233\cdot4$. Loss at 110°, not more than 2%. Soluble barium compounds and sulphide, sulphite and thiosulphate are among the impurities tested for. The *U.S.P. XII* excludes barium sulphate which does not comply with a test for bulkiness of powder; on shaking 1 part by weight with water in a cylinder and adjusting to 10 volumes, shaking for 1 minute and standing 15 minutes the sediment measures not less than 2·4 volumes; acid-soluble substances, dried at 100° to 110° (in which no soluble barium salts are precipitated by sulphuric acid within 30 minutes), not more than 0·3%. Tests for sulphide, free acid or alkali, phosphate and heavy metals are included. The *P. Helv. V* gives the same bulkiness of powder test, but it should occupy not less than 3 volumes.

Baryta Sulphurata (B.P.C.). Contains not less than 60% of BaS. Assayed by titration with ammoniacal zinc solution, using alkaline lead indicator externally.

BELLADONNA

Belladonnæ Folium (B.P. Add. V). The leaves of *Atropa Belladonna*, Linn. or of *Atropa lutescens* Jacquem. (*Indian Belladonna*). The leaf of *Atropa Belladonna* contains not less

Belladonnæ Folii, N.F. VII, contains 0.27 to 0.33% *w/v* of alkaloids of belladonna leaf.

Extractum Belladonnæ Siccum (B.P.). Contains 0.95 to 1.05% of alkaloids of Belladonna leaf, calculated as hyoscyamine. **Extractum Belladonnæ, U.S.P. XII**, yields 1.15 to 1.35% of alkaloids. Assayed by the general method for hyoscyamus alkaloids. The powdered extract contains 1.25% of alkaloids of belladonna leaf, assayed similarly.

Assay of Extracts. The following method of assay of extract of belladonna is based on that of the German Pharmacopœia. 3 g. of the extract is dissolved in 5 ml. of warm water, and, after cooling and the addition of 2.0 g. of ammonia, shaken with 30 g. of ether. 1 g. of powdered tragacanth is added, and the mixture is strained through cotton wool. 20 g. of the ethereal solution is evaporated to dryness, the residue is dissolved in 2 ml. of alcohol, and titrated with N/100 hydrochloric acid, using methyl red as indicator. The method for belladonna leaf is as follows:—10 g. of powdered leaf is treated with 100 g. of ether and 7.0 g. of ammonia solution. After shaking at intervals during 30 minutes the liquid is strained off. The filtrate is mixed with 5 ml. of water, shaken well, allowed to stand, and filtered; 60 g. of the filtrate is evaporated to dryness and the residue dissolved in 10 ml. of ether. After adding 25 ml. of 0.25% hydrochloric acid and shaking, the ether is evaporated off and the liquid cooled and made up to 30 g. with 0.25% hydrochloric acid. The mixture is then shaken with 0.5 g. of talc and filtered, 25 g. of the filtrate being made alkaline with ammonia and shaken out three times with chloroform. The extract is filtered and evaporated to dryness, the residue is dissolved in 2 ml. of alcohol, 5 ml. of water is added, and the mixture is titrated with N/100 hydrochloric acid. For tincture of belladonna, 50 g. of the tincture is evaporated to 5 g. and treated with 50 g. of ether and 5 g. of ammonia. Further treatment is then as described above for the leaf, taking 40 g. of the ethereal solution.—A. Jermstad, *Norsk farm. Tidsskr.*, 1936, 44, 294.

Assay of Tablets. A satisfactory method is described to replace that in *U.S.P. XI* which is stated to be useless for tablets.—D. T. Wilson, *J. Amer. pharm. Ass.*, 1938, 27, 398.

Linimentum Belladonnæ (B.P.). Contains 0.350 to 0.400% *w/v* of alkaloids of Belladonna Root. Alcohol content 70 to 75% *v/v* of ethyl alcohol.

Tinctura Belladonnæ (B.P. Add. V). Contains 0.028 to 0.032% of alkaloids. **Tinctura Belladonnæ, U.S.P. XII**, contains 0.027 to 0.033% *w/v* of alkaloids of belladonna leaf.

Unguentum Belladonnæ, U.S.P. XII, yields 0.110 to 0.140% of alkaloids of belladonna leaf. Assayed by repeated extraction with chloroform from the ammoniacal liquid, completing by the general method for solanaceous alkaloids.

Atropina (B.P.). $C_{17}H_{23}O_3N = 289.2$. M.p., 114° to 116°. Ash, not more than 0.1%. Tests for limit of *l*-hyoscyamine and absence of apoatropine are included. The *U.S.P. XII* alkaloid is required to comply with the platonic chloride test for most other alkaloids and with tests for apoatropine and belladonnine.

An official method for the determination of atropine in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 582)*. The atropine, extracted with chloroform from ammoniacal solution, is dissolved in a known excess of standard acid and back-titrated with standard sodium hydroxide, using methyl red as indicator.

Colorimetric Assay. A rapid method for the determination of atropine, hyoscyamine, and hyoscyne in hypodermic tablets or injections is described. The method depends upon a modification of Vitali's test and tables are given relating the red component of the colour obtained to the alkaloidal content. Details are also given for the determination of solanaceous alkaloids in the

presence of morphine which is removed by oxidation with 5% ferric chloride solution followed by extraction of the atropine in the usual manner after addition of sodium citrate and ammonia.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 240.

Atropinæ Sulphas (B.P. Add. I and VI).

$(C_{17}H_{23}O_3N)_2 \cdot H_2SO_4 \cdot H_2O = 694.5$. M.p., after powdering and drying at 135° for exactly 10 minutes, not lower than 188° . Loss at 136° , not more than 3%; ash, not more than 0.1%. A test for absence of apoeptropine is included. The salt is official in the *U.S.P. XII*; 0.2 g. in 5 ml. of sulphuric acid is required to produce no more colour than a specified control liquid. Atropinum sulphuricum, *P. Helv. V*, by titration of 5 ml. of standard solution and 3 ml. of chloroform with N/10 sodium hydroxide using phenolphthalein indicator, contains at least 99.3% of $(C_{17}H_{23}O_3N)_2 \cdot H_2SO_4$.

The melting-point is affected by the last minute trace of water which is not worth considering in the moisture determination, and it is therefore determined on the sample dried at 136° . When dried at this temperature the salt is comparatively stable in air.—T. A. Henry, *Pharm. J.*, i/1933, 86.

Tabellæ Atropinæ Sulphatis (U.S.P. XII). Tablets of 20 mg. or more contain 93 to 107% of the labelled amount of $(C_{17}H_{23}O_3N)_2 \cdot H_2SO_4 \cdot H_2O$, and tablets of less than 20 mg. contain 90 to 110% of the labelled amount, including all tolerances. For the assay a weighed quantity of powdered tablets is macerated with water and diluted sulphuric acid overnight. An aliquot of the filtrate is made alkaline with ammonia solution and extracted with chloroform. After removal of the chloroform the residue is dissolved in excess N/50 sulphuric acid and the solution titrated with N/50 sodium hydroxide, using methyl red indicator.

Homatropinæ Hydrobromidum (B.P.). $C_{16}H_{21}O_3N \cdot HBr = 356.1$. M.p. with partial decomposition, about 214° ; ash, not more than 0.1%. Homatropinæ Hydrobromidum, *U.S.P. XII*, melts at 212° and should also comply with a test for alkaloid precipitated with tannic acid, and a test for alkaloids giving the Vitali reaction. It is also required to give no precipitate with platinic chloride.

An official method for the determination of homatropine in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 586)*. The homatropine, extracted with chloroform from ammoniacal solution, is dissolved in excess standard sulphuric acid and back-titrated with standard sodium hydroxide, using methyl red as indicator.

Eucatropinæ Hydrochloridum (U.S.P. XII). $C_{17}H_{21}O_3N \cdot HCl = 327.8$. Dried over sulphuric acid, contains 86 to 89% of the base, $C_{17}H_{21}O_3N$. Assayed by extraction with ether from an ammoniacal solution and drying the base at 80° . M.p., not below 83° ; ash, not more than 0.1%. (This substance was previously available in this country under the trade name of Euphthalmine—see Vol. I, 21st Edn.)

BISMUTHUM

Bismuthi Carbonas (B.P. Add. I). Residue of Bi_2O_3 on ignition, 90 to 92%. Limit tests for lead, copper, sulphate, alkalis and alkaline earths, nitrate and chloride are included and also a test for absence of silver. Bismuthi Subcarbonas, *U.S.P. XII*, after drying over sulphuric acid for 18 hours yields, on ignition, not less than 90% of Bi_2O_3 . Carbonate de Bismuth, *Fr. Cx*.

1937, yields 89 to 92% of Bi_2O_3 . Bismutum subcarbonicum, *P.G. VI*, contains 80.7 to 82.5% of bismuth. Bismutum subcarbonicum, *P. Helv. V*, corresponding approximately to the formula $(\text{BiO})_2\text{CO}_3 + \frac{1}{2}\text{H}_2\text{O}$ or $(\text{BiO})_2\text{CO}_3$, yields 90 to 92% of Bi_2O_3 . The residue of Bi_2O_3 obtained in the assay dissolved in hydrochloric acid should not produce a red coloration (selenium).

Tabellæ Bismuthi Subcarbonatis (N.F. VII). Yield Bi_2O_3 , not less than 83% and not more than 97% of the labelled amount of bismuth subcarbonate, including all tolerances. Assayed by heating to destroy organic matter, cooling and adding nitric acid, heating carefully and then igniting at a temperature below the fusion point of bismuth oxide. The residue is cooled, dissolved in nitric acid, the solution diluted to volume with 1% nitric acid and filtered. An aliquot of the filtrate is made alkaline with ammonia solution; the bismuth is precipitated with ammonium carbonate solution, heated on a steam-bath for 1 hour, collected on a tared Gooch crucible, washed and finally ignited to Bi_2O_3 .

A tentative method for the determination of bismuth compounds in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 617)*.

Bismuthi Citras (B.P.C.). Residue of Bi_2O_3 , on ignition and re-ignition with nitric acid, not less than 55% and not more than 59%.

Liquor Bismuthi et Ammonii Citratis (B.P.C.). The following assay process is recommended as being more satisfactory than that of the *B.P.C.*: Dilute 10 ml. to 100 ml. To 25 ml. of the dilution add 50 ml. of water and sufficient nitric acid to produce a ppt. and to re-dissolve it. Add 25 ml. of water and strong solution of ammonia until a permanent ppt. is obtained, then add 2 ml. of nitric acid and heat to boiling. Add to the boiling solution a 10% solution of ammonium phosphate, at the rate of about 30 drops per minute, until all the bismuth is precipitated, then more quickly until 40 ml. in all has been added. Dilute to about 400 ml. with boiling water, heat on a water-bath for 15 minutes, filter through a Gooch crucible, wash by decantation three times and then on the filter with a 3% solution of ammonium nitrate containing a few drops of nitric acid, dry, ignite and weigh. 1 g. of BiPO_4 is equivalent to 0.7654 g. of Bi_2O_3 .—C. T. Bennett and N. R. Campbell, *Quart. J. Pharm.*, 1932, 515.

Bismuthi et Potassii Tartras (U.S.P. XII). By precipitation as phosphate contains the equivalent of 60 to 64% of Bi; alcohol-soluble extractive, not more than 0.5%.

Bismuthi et Sodii Tartras (B.P. Add. I). Contains 35 to 42% of Bi, determined by precipitation with ammonium phosphate and ignition. Complies with limit tests for lead and for copper.

Bismuthi et Sodii Tartras Acidus (B.P.C. Supp. V). By precipitation as sulphide, reprecipitation as carbonate, and ignition to oxide, it contains from 38 to 44% of Bi.

Bismuthi Hydroxidum. Corfield and Woodward were unable to substantiate the formula $\text{BiO} \cdot \text{OH}$ for a body made by the *Fr. Cx.* or other method. The only pure compound they could obtain was one of the formula $\text{Bi}(\text{OH})_3$.—*Pharm. J.*, i/1924, 83.

Bismuthi Oxyiodogallas (B.P.C.). Assayed for I content by solution in sodium hydroxide, boiling with N/10 silver nitrate

and nitric acid and back titration with N/10 ammonium thiocyanate, it contains not less than 20%. Residue of Bi_2O_3 , 43 to 45%. Bismutum oxyiodogallicum, *P. Helv. V*, should contain 20 to 24.5% of iodine and yield from 45 to 48.5% of Bi_2O_3 . Iodine is determined by boiling with N/10 silver nitrate and nitric acid until nitrous vapours cease to be evolved and the silver iodide is yellow; the diluted solution is then treated with potassium permanganate until a violet colour persists 1 minute, decolorised with ferrous sulphate and titrated with ammonium thiocyanate. Bi determined by treatment with nitric acid, evaporation and ignition.

Bismuthi Salicylas (B.P.). Residue on ignition and re-ignition, not less than 62% and not more than 66% of Bi_2O_3 . A limit of free salicylic acid of 0.1% is included. Bismuthi Subsalicylas, *U.S.P. XII*, after drying to constant weight at 100°, yields 62 to 66% of Bi_2O_3 . Bismutum subsalicylicum, *P.G. VI*, contains 56.5 to 58.5% of bismuth. The *Fr. Cx.* 1937 requires the same Bi_2O_3 content as the *U.S.P. XII*. Bismutum subsalicylicum, *P. Helv. V*, corresponds approximately to the formula $\text{C}_6\text{H}_4(\text{OH})\text{COOBiO}$ and yields 63 to 65.2% of Bi_2O_3 .

Bismuthi Oxychloridum (B.P. Add. I) determined by precipitation as phosphate and ignition, has a Bi content of 79 to 81%, and a Cl content of not less than 12.5% by titration with silver nitrate and ammonium thiocyanate. Limit tests for lead, copper and sulphates are included and a nitrates limit:—Add 5 ml. of indigo carmine solution and 15 ml. of nitrogen-free sulphuric acid in 2 portions to 0.5 g. in 10 ml. of water, boil and set aside for 1 minute; the blue colour should not be entirely discharged.

Bismuthi Subgallas (B.P. Add. IV). Loses not more than 5% at 100°, and then yields by re-ignition with nitric acid from 52 to 57% of Bi_2O_3 . Limit of free gallic acid, by solubility in alcohol (90%), not more than 0.25%. The *N.F. VII* salt has the same standard on the substance dried at 100° for 3 hours. Gallate de Bismuth, *Fr. Cx.* 1937, yields not less than 52% Bi_2O_3 . Bismutum subgallicum, *P. Helv. V*, yields 52 to 56.5% of Bi_2O_3 .

Tabellæ Bismuthi Subgallatis (N.F. VII). Yield Bi_2O_3 , not less than 48% and not more than 61% of the labelled amount of bismuth subgallate, including all tolerances. Assayed by the process described for bismuth subcarbonate tablets.

Bismutum bitannicum (P. Helv. V). By ignition, evaporation with nitric acid and re-ignition, contains 20 to 24% of Bi_2O_3 . Free tannic acid, by agitation for 2 minutes with 10 volumes of alcohol, filtration and drying at 103° to 105°, not more than 1.2%.

Bismuthi Subnitras (B.P.C. Add. V). Residue of Bi_2O_3 , not less than 79% and not more than 81%. Complies with tests for absence of silver and limits of chloride, sulphate, alkalis and alkaline earths, lead, and copper. Dissolves completely without effervescence in an equal quantity of warm nitric acid. Bismuthi Subnitras, *U.S.P. XII*, yields not less than 79% of bismuth oxide

after drying over sulphuric acid. Azotate Basique de Bismuth Lourd, *Fr. Cx.* 1937, yields 79 to 81% of Bi_2O_3 and contains 15.5 to 17% of N_2O_5 , determined by treatment with ferrous sulphate solution and back titration with N/10 potassium permanganate. Azotate Basique de Bismuth Léger, *Fr. Cx.* 1937, yields 82 to 89% of Bi_2O_3 . Bismutum subnitricum, *P.G. VI*, contains 70.9 to 73.6% of bismuth. Bismutum subnitricum, *P. Helv. V*, contains 79 to 82% of bismuth calculated as Bi_2O_3 and is stated to correspond approximately to the formula $\text{Bi}(\text{OH})_2\text{NO}_3 + \text{OBiNO}_3 + \text{OBiOH}$ or $2\text{Bi}(\text{OH})_2\text{NO}_3 + \text{OBiOH}$.

The proportion of N_2O_5 in this and other nitrates may be determined by the following method of the Board of Agriculture and Fisheries (Leaflet No. 18, p. 116):—

To 0.5 g. in a 500 ml. Erlenmeyer flask add 50 ml. of water and 20 ml. of sulphuric acid (sp. gr., 1.35) followed by 10 g. of reduced iron. Close the flask with a rubber cork through which passes a thistle funnel the head of which is half filled with glass beads, boil for five minutes and wash back into the flask any liquid among the beads. Boil for three minutes, then distil with 50 ml. of 50% sodium hydroxide, collecting the ammonia evolved in 50 ml. of N/10 sulphuric acid, and back titrate the excess acid with N/5 alkali. Conduct a blank experiment under the same conditions.—C. E. Corfield and G. R. A. Short, *Yearb. Pharm.*, 1924, 573.

Dragendorff's Test for alkaloids. Bismuth subnitrate 8, nitric acid, sp. gr. 1.18, 20; add this solution gradually to a concentrated solution of potassium iodide, 22.7. Cool, decant from potassium nitrate formed, and dilute to 100 with water. The solution precipitates most alkaloids.

A suggested modification:—Dissolve bismuth carbonate 64 in hydrochloric acid 85 and add water 500 containing potassium iodide 166. Finally make up with water to 800. This eliminates nitric acid which causes decomposition, and the proportion of potassium iodide is less. With this formula there is no trouble with crystals of potassium nitrate.

Thresh's Reagent. Bismuth citrate 2.4 g., water 20 ml., ammonia q.s., made up to 30 ml. with water and added to a solution of potassium iodide 2 g. in nitric acid 45 ml. Is similar in use to above.

Tabellæ Bismuthi Subnitratis (N.F. VII). Yield Bi_2O_3 , not less than 73% and not more than 85% of the labelled amount of bismuth subnitrate, including all tolerances. Assayed by the process described for bismuth subcarbonate tablets.

Bismuthi Tribromphenas (B.P.C. Supp. IV). Assayed by precipitation, as for the subchloride, after decomposition with sodium hydroxide and dissolving the precipitate in nitric acid, it contains not less than 47% and not more than 49.5% of Bi. A limit of free tribromophenol, by addition of excess sodium hydroxide to the alcohol-soluble matter and titration with standard hydrochloric acid, is equivalent to about 3%. Bismutum tribromphenylicum, *P.G. VI*, should contain not less than 44.9% of bismuth. Bismutum tribromphenylicum, *P. Helv. V*, yields from 50 to 55% of Bi_2O_3 .

Bismuthum Præcipitatum (B.P. Add. I). Determined by precipitation as phosphate, and ignition, it contains not less than 98.5% of metallic bismuth. In the limit test for silver the substance is dissolved in hydrochloric acid with potassium chlorate, evaporated to remove chlorine, diluted with hydrochloric acid and tested with potassium iodide solution. A limit test for copper is included.

Detection of Silver in Bismuth Salts.

Dissolve 0.02 g. of bismuth carbonate in 2 ml. of dilute hydrochloric acid; add 2 ml. of 0.03% solution of *p*-dimethylaminobenzylidene-rhodanin and 1.8 ml. of distilled water. Add a few drops of water if necessary to make the liquid turbid. In the presence of 1 in 40,000 of silver the precipitate is red to violet. For bismuth salicylate, heat to boiling 0.5 g. with 5 ml. of dilute hydrochloric acid, shaking the tube. To 2 ml. of filtered liquid add 2 ml. of the above reagent and 3.8 ml. of water, or more if necessary, to produce turbidity. In the presence of 0.002% of Ag the ppt. is coloured violet.—J. F. Reith, *Pharm. J.*, i/1933, 316.

Sensitive Colour Reactions for Bismuth.

To a suitable volume of the aqueous solution to be tested, e.g. 10 ml., add 2 ml. of dilute hydrochloric acid and 0.5 g. of potassium iodide. Mix, and add 5 ml. of acetone or industrial spirit and 5 ml. to 10 ml. of ethyl acetate. Shake and allow to separate; a red coloration in the upper layer indicates bismuth. By suitable modification the test can be applied quantitatively and is suitable for the rapid determination of bismuth in urine and animal tissues.—A. D. Powell, *Quart. J. Pharm.*, 1933, 465.

Traces of bismuth in the presence of other metals can be separated by extraction, after preliminary treatment, with a solution of diphenylthiocarbazon in chloroform. After further treatment the bismuth compound is extracted with a mixture of 3 parts of amyl alcohol and one part of ethyl acetate. The colour of the solution is compared with those obtained from known amounts of bismuth.—L. A. Haddock, *Analyst*, 1934, 163.

Quinine Iodobismuthate. It should pass the following tests. It should dissolve completely in acetone containing a little water, and 0.25 g. shaken with 5 ml. of chloroform should not impart a violet colour to the latter (free iodine). It should not lose more than 1% when dried at 100°. The three components can be estimated by dissolving the substance in a little acetone, adding silver nitrate, which precipitates the iodine and the bismuth, dissolving the bismuth from the precipitate with nitric acid, leaving the silver iodide. The quinine may be determined polarimetrically in the first filtrate. The author suggests the following standards: bismuth 24.30%, quinine 17.50%, iodine 58.0%.—G. Vita and L. Bracaloni, per *Quart. J. Pharm.*, 1937, 81.

Assay. Dissolve 1 g. of sample in 10 ml. of acetone, add 0.09 g. of silver nitrate in 20 ml. of water, and heat to drive off the acetone. Then add 50 ml. of alcohol and allow the precipitate to settle. Pour off the clear liquid containing quinine nitrate through a Gooch crucible, wash the precipitate with warm alcohol by decantation, pouring the washings through the Gooch crucible, evaporate the filtrate and washings to small bulk, add 4 ml. of N/1 sulphuric acid and dilute to 50 ml. Determine the quinine in this solution polarimetrically. The precipitate of silver iodide and basic bismuth nitrate is washed with a mixture of nitric acid and water, equal parts, and transferred to the crucible with more dilute nitric acid. It is then washed, dried, and weighed. The dilute nitric acid filtrate is treated with excess of ammonium carbonate, the liquid boiled, and the precipitate washed, dried, ignited and weighed as Bi_2O_3 .—N. Bracaloni, *J. Pharm. Chim., Paris*, ii/1935, 49.

The quinine is determined by adding sodium hydroxide to an aqueous solution of the compound and extracting the precipitated alkaloid with chloroform, evaporating the latter and weighing. The aqueous solution is acidified with nitric acid and the liberated iodine extracted with chloroform. The solution of iodine in the chloroform is diluted with alcohol, 1 or 2 g. of sodium bicarbonate added and the iodine titrated with N/10 sodium thio-sulphate. The residual aqueous solution is boiled to remove the chloroform, neutralised with sodium hydroxide, made slightly acid and saturated with hydrogen sulphide to precipitate the bismuth. The latter is collected, washed with hydrogen sulphide water, alcohol, ether and carbon disulphide and weighed.—G. N. Thomis and G. P. Kopanaris, *J. Pharm. Chim., Paris*, 1939, 30, 193.

Determination of Bismuth. About 1 g. is mixed in a warm 150 ml. beaker with 10 ml. of acetone and stirred with a mixture of 5 ml. of 20% tartaric acid solution and 5 ml. of 30% sodium hydroxide solution free from halogen. When the solution is decolorised, 20 ml. of water is added, the mixture heated for 30 minutes on a boiling water-bath, cooled and filtered, the beaker being rinsed with a total of 50 ml. of water. 125 ml. of 16% ammonium carbonate

solution is added, the mixture heated on a boiling water-bath for 4 hours and then allowed to stand for 24. The precipitated bismuth carbonate is washed by decantation, filtered, dried, ignited, and weighed as Bi_2O_3 .—M. François and L. Seguin, *J. Pharm. Chim., Paris*, i/1937, 341.

Determination of Bismuth in Biological Material. The material is digested with sulphuric and perchloric acids in a Kjeldahl flask until all the organic material is destroyed and the excess of perchloric acid has been driven off. The digest is diluted with water, 20% sodium citrate solution added and the mixture made alkaline to pH 8 with ammonia. A 2% solution of sodium diethyldithiocarbamate is added and the mixture extracted three times with ether. The combined ethereal extracts are evaporated to dryness in a Kjeldahl flask, and the organic material destroyed by heating with 1 ml. of concentrated sulphuric acid and 1 ml. of perchloric acid. After cooling, the mixture is diluted with water and a 10% thiourea solution added. The colour of the solution is compared with a standard made from a solution of bismuth in 20% sulphuric acid mixed with 5% thiourea solution.—S. L. Tompsett, *Analyst*, 1938, 250.

BUCHU

Buchu (*B.P. Add. I*). The dried leaves of *Barosma betulina* (Thunb.) Bartl. and Wendl. only. Contains not more than 5% of its stem. Other foreign organic matter, not more than 2%. Ash, not more than 5%. Yields not less than 20% of alcohol (25%) soluble extractive. The *N.F. VII* allows the dried leaf of *Barosma betulina* (Thunberg) Bartling et Wendland (Short Buchu) or of *Barosma crenulata* (Linné) Hooker (oval buchu) or of *Barosma serratifolia* (Curtis) Willdenow (long buchu). It should contain not more than 8% of its stems, not more than 2% of other foreign organic matter, not more than 1% of acid-insoluble ash, and not less than 1.25% *v/w* of volatile oil determined by the method prescribed.

An account of the histology of buchu and of the leaves of other species of *Barosma*. A key is given for the identification of the powdered leaves of various species of *Barosma*.—T. E. Wallis and T. Dewar, *Quart. J. Pharm.*, 1933, 347.

Uva Ursi (*B.P.C.*). Contains not more than 5% of foreign organic matter.

Determination of Arbutin. 0.5 to 2.5 g. of bearberry is macerated in boiling water for one hour. The liquid is filtered, the residue washed and the mixed filtrate and washings rendered alkaline with ammonia. 20 ml. of filtered 10% lead acetate solution is added, the mixture heated on a water-bath for 15 minutes, then allowed to stand 2 hours and filtered through a Buchner filter. The filtrate is freed from lead by means of hydrogen sulphide and again filtered, the product being boiled to remove excess of hydrogen sulphide. The solution is made alkaline with ammonia, 1 ml. of 10% phosphomolybdic acid solution is added and then water to 500 ml. The colour produced is tested against known quantities of a standard arbutin solution treated similarly with phosphomolybdic acid. The process is applied to a liquid extract by diluting 1 to 5 ml. to 200 ml., filtering and washing, and treating the liquid thus obtained as described above for the infusion of the crude drug.—J. E. Ball and C. O. Lee, *J. Amer. pharm. Ass.*, 1937, 698.

CAFFEINA

Caffeina (*B.P.*). $\text{C}_8\text{H}_{10}\text{O}_2\text{N}_4\cdot\text{H}_2\text{O}=212.1$. M.p., after drying at 100° , 235° to 237° . Loss at 105° , not more than 8.5%. Ash, not more than 0.1%. Caffeina, *U.S.P. XII*, should lose not more

than 9% of its weight at 80°. Ash limit, 0.1%. Tests for carbonisable substances and heavy metals are included.

Caffeine and theobromine give no precipitate with Mayer's reagent, distinguishing them from the majority of alkaloids. Tea contains a minimum of 3.5% of caffeine and a maximum of 4.0%. Raw coffee, about 1.2%, and when roasted, about 1.3%. For manufacture, tea dust with the largest yield of alkaloid is extracted.

Tea. When there is neither caffeine nor tannin present in quantity exceeding that which the compound of them (caffeine tannate) contains, the tea is pronounced by the taster as of good quality. Caffeine and tannin occur mostly (in good teas) in the ratio of 1:3, which is virtually the ratio in caffeine tannate. Cold water extracts only a very small proportion of the total caffeine in tea, though solubility is 1.35% at 16°. Caffeine is taken up always as tannate.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined tea as the tender leaves, leaf buds, and tender internodes of different varieties of *Thea sinensis* L., prepared and cured by recognised methods of manufacture; conforms in variety and place of production to the name it bears; ash, 4 to 7%.—S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.

Coffee. The caffeine in tea, being in the form of caffeine tannate, is precipitated by the gastric juice and, therefore, the caffeine is probably not absorbed until it reaches the alkaline alimentary tract. In the case of coffee, however, in whatever form the caffeine may be present it is soluble in both alkaline and acid fluids and, therefore, the absorption in this case is probably in the stomach, hence the more prompt action as restorative.

Extracts purporting to be pure coffee are comparatively rare, coffee and chicory extracts being the commoner. But judging from samples received the caffeine in the two classes does not differ much, the coffee extracts (12 in number) containing from 0.1 to 0.33% of caffeine (average 0.21), and the 45 coffee and chicory extracts containing from 0.05 to 0.38% (average 0.19), though there might be some doubt about the designation of some of the coffee extracts. A dry extract examined contained 6.8% of caffeine. Taking the caffeine as a basis of evaluation, the poorest extracts gave a "coffee" only of from one-tenth to one-fifth the strength of ordinary breakfast coffee made from the berry, and even at the best they were but a poor approach to the real article.—E. Hinks, *Lancet*, i/1936, 387.

Decaffeinated Coffee. The amount of caffeine removal in current specimens approximates well over 90%, assuming that 1.2% of caffeine by weight was originally present.—*J. Amer. med. Ass.*, ii/1928, 883.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined coffee as the seed of cultivated varieties of *Coffea arabica*, *C. liberica*, and *C. robusta*. Green coffee, raw coffee, unroasted coffee—coffee with only a small portion of its spermoderm, conforming in variety and place of production to the name it bears. Roasted coffee, ("coffee") properly cleaned green coffee which has become brown by roasting and has developed its characteristic aroma.—S.R.A., F.D. No. 2, Rev. 5, Nov. 1936.

Caffeina Citras (B.P.C.). $C_8H_{10}O_2N_4 \cdot C_6H_5O_7 = 386.2$. By extraction with chloroform from a solution made alkaline with sodium hydroxide and drying at 100°, the anhydrous caffeine obtained is from 46 to 51%. Loss at 80°, not more than 5%. Ash, not more than 0.1%. Caffeina Citrata, U.S.P. XII, loses not more than 5% at 80° and then contains from 48 to 52% of anhydrous caffeine. Ash limit, 0.1%. Caffeinum citricum, *P. Helv. V*, contains not more than 2% of moisture and from 48.8 to 50.8% of anhydrous caffeine. **Assay:** Dissolve 0.5 g. in 2.5 ml. of water; add, after cooling, 25 g. of chloroform and 2 g. of 30% solution of sodium hydroxide, and shake for 5 minutes; add 0.5 g. of powdered tragacanth and shake again. After 5 minutes, filter and distil off the chloroform from 20 g. of the filtrate in a tared flask; dry the residue for 30 minutes at 103°

to 105° and weigh, adding 0.0017 g. of caffeine to the weight obtained. The result gives the weight of anhydrous caffeine in 0.4 g. of the caffeine citrate.

Tabellæ Caffeinæ Citrati (N.F. VII). Contain $C_8H_{10}O_2N_4$, not less than 43% and not more than 53% of the labelled amount of citrated caffeine, including all tolerances. Assayed by dissolving as completely as possible in water, making alkaline with sodium hydroxide solution, extracting with chloroform, filtering each chloroform extract, removing the chloroform and drying the residue at 80°.

Caffeina et Sodii Benzoas (B.P.). The dried substance contains 47 to 50% of $C_8H_{10}O_2N_4$ and 50 to 53% of $C_7H_5O_2Na$. Loss at 105°, not more than 5%. Caffeine is determined as in Caffeinæ Citras; benzoic acid is extracted with ether from the aqueous liquids and washings from the caffeine extraction made acid with dilute sulphuric acid; after evaporation of the ether, the residue is titrated in alcoholic solution with N/10 sodium hydroxide to phenol red and calculated to the sodium compound. M.p. of the separated caffeine, 235° to 237°, and of the separated benzoic acid, 121° to 122°. Caffeina et Sodii Benzoas, U.S.P. XII, loses not more than 3% at 80° and then contains 47 to 50% of anhydrous caffeine and 50 to 53% of sodium benzoate. In the assay, the caffeine is extracted with chloroform from solution made just alkaline to phenolphthalein with N/10 sodium hydroxide, drying the separated caffeine at 80°; the liquid from which the caffeine has been separated is mixed with ether and the benzoic acid titrated with N/10 hydrochloric acid to methyl orange indicator. Coffeinum-Natrium benzoicum, P.G. VI, contains not less than 38% of anhydrous caffeine.

Tabellæ Caffeinæ cum Sodii Benzoate (N.F. VII). Yield $C_8H_{10}O_2N_4$ not less than 43.5% and not more than 53.5% of the labelled amount of caffeine with sodium benzoate, including all tolerances. Assayed by the process described for citrated caffeine tablets.

Caffeina et Sodii Salicylas (B.P.C.). Assayed as Caffeina et Sodii Benzoas, it contains 47 to 50% of anhydrous caffeine, and 50 to 53% of sodium salicylate, calculated with reference to the substance dried at 105°. Loss at 105°, not more than 5%. Caffeina cum Sodii Salicylate, N.F. VII, contains 48 to 52% of anhydrous caffeine and 48 to 52% of sodium salicylate, after drying at 80°. After extraction of the caffeine with chloroform from a solution made alkaline with sodium hydroxide, the salicylate is determined by treatment during 30 minutes with N/10 bromine and hydrochloric acid, and the iodine liberated from potassium iodide titrated with standard thiosulphate. Coffeinum-Natrium Salicylicum, P.G. VI, should yield not less than 40% of anhydrous caffeine. It is assayed as follows:—

Dissolve 0.5 g. of caffeine sodium salicylate in 1 ml. of water in a 50 ml. measure. Add to the solution 25 g. of chloroform and 2.5 g. of sodium hydroxide solution. Shake thoroughly for 5 minutes. After adding 0.3 g. of tragacanth, shake again for several minutes, and after a further 5 minutes pour 20 g. of the chloroform solution (equivalent to 0.4 g. of the sample) through a little

wool into a weighed flask. On evaporating the chloroform and drying the residue at 100° , the residue must be at least 0.16 g., representing 40% of caffeine.

Caffeinae Hydrobromidum (B.P.C.). $C_8H_{10}O_2N_4 \cdot HBr \cdot 2H_2O$ = 311.1. Yields from 60 to 63% of anhydrous caffeine. Ash, not more than 0.1%.

Guarana (B.P.C.). Contains not less than 3.5% of caffeine, calculated as anhydrous. Assayed by maceration with chloroform and ammonia, evaporation of an aliquot part of the filtered solution, solution of the residue in warm N/5 sulphuric acid and extraction of the filtered liquid, made alkaline with sodium hydroxide, with chloroform, finally evaporating and drying at 100° . Guarana, *N.F. VII*, yields not less than 4% of caffeine, by a similar extraction; acid-insoluble ash limit, 0.5%.

Theobromina (B.P.C.). $C_7H_8O_2N_4$ = 180.1. Loss at 100° , not more than 3%. Ash, not more than 0.1%. A caffeine limit, by extraction with chloroform from sodium hydroxide solution, is equivalent to 1%.

A method for the determination of theobromine in tablet mixtures. The method consists in the gravimetric precipitation of the insoluble compound formed by the action of phosphato-dodecatungstic acid on hot strongly acidified solutions of the tablet mixture. The precipitate is filtered while hot, washed, dried and weighed.—A. G. Richardson and Y. C. Campbell, *J. Amer. pharm. Ass., Sci. Edn.*, 1942, 24.

The second report of the Commission Internationale des Spécialités includes an agreed method for the determination of theobromine in tablets or other preparations containing salicylates in which by the addition of silver nitrate, a theobromine-silver compound is formed and the liberated nitric acid is titrated with alkali to phenol red.—*Bull. Féd. int. Pharm.*, 1938, 89.

Tentative methods for the determination of theobromine in theobromine calcium, and in tablets of theobromine calcium are described in *Methods of Analysis (A.O.A.C., 1940, 593)*.

Cocoa. The ground nibs of *Theobroma Cacao* from which most of the fat has been removed. Cocoa is sometimes treated with an alkali or an alkaline salt, such as potassium carbonate, to render it "soluble," the alkali probably producing a more perfect emulsion of the fat. Before and after treatment with alkali, cocoa shows essentially the same lack of solubility, and hence the designation "soluble cocoa" is misleading and deceptive.

In pure untreated cocoa, the ash should generally be below 5.5%, with an alkalinity not exceeding 3.75; while with cocoas treated with alkali the ash is often as high as 8.5%, with an alkalinity exceeding 6. (Azor Thurston, *Pharmaceutical and Food Analysis*, 1923.) A number of samples were examined in 1925 by W. H. Martindale, and it was found that in several cases the high ash and alkalinity were suggestive of the use of alkali in their preparation. The % ash varied from 2.8 to 7.5, the average being 5.7. The alkalinity varied from 3.5 to 11.0, the average volume of N/10 acid required to neutralise 1 g. being 7.5 ml. None of the samples contained added starch. When treated with water as directed, the samples with high alkalinity did not give a better suspension than the untreated samples. The examination of a number of cocoas on the market showed moisture to range from 3 to 8%. Nitrogenous matter (N \times 6.3) 19 to 20%, fat 26 to 31%, mineral matter 3.9 to 8.8%, theobromine 1.7 to 2%.

Cacao (N.F. VII). Non-volatile ether-soluble extractive, not more than 22%. The dried ether-insoluble residue yields not more than 7% of crude fibre, ash not more than 8% and acid-insoluble ash not more than 0.4%.

Theobromina et Sodii Salicylas (B.P.). Loss at 110° , not more than 5%, and then contains not less than 46% of $C_7H_8O_2N_4$,

not less than 41% of $C_7H_5O_3Na$, and not more than 6.9% of Na additional to that contained in the sodium salicylate. Assayed by the processes of the *B.P.* '32; for theobromine, about 1 g. in 10 ml. of water is shaken with 2 ml. of N/1 sodium hydroxide and 0.6 ml. of dimethyl sulphate for five minutes and set aside, with frequent shaking, for thirty minutes; a further 3 millilitres of N/1 sodium hydroxide is added and shaken well for one or two minutes, and the caffeine extracted immediately with successive portions of chloroform; the washed mixed chloroform solutions are evaporated and dried at 100° for 1 hour; 1 g. of the anhydrous caffeine obtained is equivalent to 0.9278 g. of $C_7H_5O_2N_4$. Salicylic acid is determined on a solution, previously acidified with dilute hydrochloric acid, from which the theobromine has been precipitated with ammonia, the mixture being allowed to stand for 3 hours, then filtered and the filtrate acidified, by extraction with ether, finally titrating in alcoholic solution with N/10 sodium hydroxide to phenol red. Additional sodium is titrated in warm aqueous solution with N/1 hydrochloric acid to phenol red. A limit test of caffeine of 0.5% is included.

The *B.P.* method can give accurate results and a clean, pure caffeine, but some workers obtain an acid residue which contains sulphate and melts at a temperature much below that of pure caffeine. It is essential for correct results to obtain a clean water-free chloroform solution before evaporation; this can be done by warming and pouring into a clean beaker or by filtering. With old samples of theobromine and sodium salicylate the volume of N/1 NaOH in the initial stage can with advantage be increased to 4 ml. and a further 10 ml. of H_2O added with the second quantity of N/1 NaOH. With more water, however, care must be taken to see that the caffeine is extracted completely. Theobromina cum Sodii Salicylate, *N.F. VII*, should yield not less than 46.5% of theobromine and not less than 35% of salicylic acid, after drying at 110° , at which temperature the loss should be not more than 10%. 2 g. of the dried substance requires not more than 5.5 ml. of N/1 hydrochloric acid to neutralise to phenolphthalein; the theobromine is filtered from this neutralised solution, made just alkaline to litmus with ammonia, and dried at 100° , a correction being added for the solubility in liquid and washings; salicylic acid is extracted from these with chloroform. Theobromino-natrium salicylicum, *P.G. VI*, contains not less than 40% of theobromine; assayed by neutralisation with N/10 hydrochloric acid to methyl red and after standing at room temperature for 3 hours, collecting the precipitated theobromine and drying at 100° . Theobromino-natrium salicylicum, *P. Helv. V*, contains not more than 5% of moisture, 10.5 to 10.7% of NaOH, and from 46.5 to 48% of theobromine. Assay for theobromine:—To a solution of 1 g. in 5 ml. of boiling water, a boiling solution of 0.5 g. of boric acid in 10 ml. of water is added, the mixture boiled and cooled till theobromine separates. Collect the precipitate after 3 hours, wash twice with 5 ml. of water, dry at 103° to 105° and weigh.

Theophyllina (*B.P. Add. I*). $C_7H_8O_2N_4 \cdot H_2O = 198.1$. M.p., 269° to 272° . Loss at 100° , not more than 9.5%. Ash, not more than 0.1%. The *U.S.P. XII* allows the same moisture limit for Theophyllina; 0.2 g. complies with the specified test for carbonisable substances.

Tabellæ Theophyllinæ (*U.S.P. XII*). Contain 94 to 106% of the labelled amount of $C_7H_8O_2N_4 \cdot H_2O$, including all tolerances. Assayed by disintegrating 20 tablets in water, adding ammonia solution and making up to volume with water, filtering and adding N/10 silver nitrate to an aliquot of the filtrate, allowing to stand 1 hour, filtering and washing the residue with water, acidifying the filtrate with nitric acid and finally titrating the excess N/10 silver nitrate with N/10 ammonium thiocyanate.

A tentative method for the determination of theophylline in solutions and tablets is described in *Methods of Analysis* (*A.O.A.C.*, 1940, 593).

Theophyllina et Sodii Acetas (*B.P.*). By treatment with dimethyl sulphate and sodium hydroxide, followed by extraction with chloroform, it yields caffeine equivalent to not less than 55% of anhydrous theophylline. Theophyllinæ et Sodii Acetatis, *U.S.P. XII*, contains 55 to 65% of anhydrous theophylline. Theophyllino-natrium aceticum, *P. Helv. V*, contains from 3 to 4% of moisture, equivalent to 1 molecule of water of crystallisation, and about 65% of theophylline, but no assay process for the latter is prescribed.

In the assay processes for Theophyllina et Sodii Acetas and Theobromina et Sodii Salicylas, the dimethyl sulphate must be in slight excess at the end of the reaction, and the caffeine must be shaken out rapidly after the addition of the sodium hydroxide, since it is quickly decomposed by strong alkalis.—*P. A. W. Self, Pharm. J.*, ii/1933, 244.

Theophylline may be determined in the presence of sodium acetate by van Giffen's modification of Boie's method, if bromocresol purple is used as indicator instead of phenol red.—*G. J. W. Ferrey, Quart. J. Pharm.*, 1940, 274.

Tabellæ Theophyllinæ et Sodii Acetatis (*U.S.P. XII*). Contain anhydrous theophylline, $C_7H_8N_4O_2$, corresponding to 53 to 67% of the labelled amount of theophylline and sodium acetate, including all tolerances. Assayed by the process described for theophylline tablets.

Theophyllina Æthylenediaminica (*U.S.P. XII*). Contains 75 to 82% of anhydrous theophylline ($C_7H_8O_2N_4$) and 12.3 to 13.8% of ethylenediamine ($C_2H_4(NH_2)_2$). Assayed for theophylline by the following process:—0.25 g. is dissolved on a steam-bath in 50 ml. of water with 8 ml. of ammonia solution. Excess N/10 silver nitrate is added and the warming continued for 15 minutes. The precipitate is filtered with the aid of a pump and washed with three portions of water. The excess silver nitrate in the cooled and acidified filtrate and washings is then titrated with N/10 ammonium thiocyanate, using ferric ammonium sulphate indicator; 1 ml. of N/10 silver nitrate is equivalent to 0.0180 g. of $C_7H_8O_2N_4$. The ethylenediamine is determined by titration with N/10 hydrochloric acid to methyl orange; 1 ml. N/10 acid is equivalent to 0.003004 g. of $C_2H_4(NH_2)_2$.

Tabellæ Theophyllinæ Æthylenediaminica (*U.S.P. XII*). Contain anhydrous theophylline, $C_7H_8N_4O_2$, corresponding to 73 to 84% of the labelled amount of theophylline ethylenediamine, including all tolerances. Assayed by the process described for theophylline tablets.

Reimer's Process. Dissolve 0.3 g. of aminophylline in 5 ml. of N/2 sodium hydroxide in a separator. Make acid to litmus paper with N/2 hydrochloric acid, then add 5 ml. more and shake for 1 minute with 25 ml. of a mixture of chloroform and isopropyl alcohol (3+1). Allow to settle for at least 5 minutes and draw off the lower layer into a second separator containing 10 ml. of water acidified with N/2 hydrochloric acid. Shake well, allow to settle for at least 5 minutes, and filter off the solvent into a tared flask through a pledget of cotton wool. Repeat the extraction with 5 more portions, each of 20 ml., of the solvent mixture, washing each time in the second separator. Evaporate the solvent,

add 2 ml. of absolute ether, evaporate, dry at 80°, and weigh the residue of anhydrous theophylline.—L. E. Warren, *J. Ass. off. agric. Chem., Wash.*, 1937, 580. See also F. Reimers, *ibid.*, 632.

The Self-Rankin process applied to aminophylline gives results that are about 3% low and occasionally the results are erratic. Possibly the method is not so satisfactory for theophylline as for theobromine. For aminophylline the Reimer's process is the most satisfactory of any tried, the results being 0.25 to 0.6% high.—L. E. Warren, *J. Ass. off. agric. Chem., Wash.*, 1937, 587.

CALCIUM

Calcii Carbonas (B.P.). $\text{CaCO}_3 = 100.1$. Loses at 100°, not more than 1% and then contains not less than 98.5% of CaCO_3 . **Calcii Carbonas Præcipitatus, U.S.P. XII**, after drying at 200°, contains not less than 98.5% of CaCO_3 and is assayed by precipitation with excess ammonium oxalate in ammoniacal solution and titration of the acidified precipitate of calcium oxalate with N/10 potassium permanganate. Acid-insoluble matter, not more than 0.2%. Limit of magnesium and alkalis, weighed as ignited sulphate, not more than 1%. **Calcium Carbonicum Præcipitatum, P. Helv. V**, contains from 98.75 to 100.5% of CaCO_3 . The bulk density of **Calcium Carbonicum Præcipitatum ad usum externum, P. Helv. V**, is controlled by the following test:—Introduce without shaking 25 g. into a 100 ml. graduated cylinder and allow the cylinder to fall lightly on the palm of the hand ten times; the powder should measure not less than 65 ml.

Tabellæ Calcii Carbonatis (N.F. VII). Contain 92.5 to 107.5% of the labelled amount of precipitated calcium carbonate, including all tolerances. Assayed by dissolving a weighed quantity of powdered tablets in dilute hydrochloric acid, filtering and adding ammonium oxalate solution to an aliquot of the filtrate made alkaline with ammonia solution, filtering and washing the residue. The precipitate and filter are transferred to a flask, dilute sulphuric acid and water added and the mixture heated to 70° and titrated with N/10 potassium permanganate.

Creta (B.P.). Dried at 100° it contains not less than 97% of the pure substance and at that temperature loses not more than 1%. It is assayed with excess of N/1 hydrochloric acid and titration with N/1 sodium hydroxide, using methyl orange as indicator. **Creta Præparata, U.S.P. XII**, contains 97%, after drying at 200°. Residue, insoluble in diluted hydrochloric acid and ignited, not more than 2%.

Prepared chalk and the precipitated variety may be readily distinguished by examination under ultra-violet light from a Hanovia lamp with Wood's screen in the dark room. Prepared chalk gives a peach or flesh-coloured fluorescence. Precipitated calcium carbonate shows a smoky, greyish-violet fluorescence. The test can be used for the identification of the chalk used in samples of Maclean's powder.—W. E. Naylor and A. Surfleet, *Pharm. J.*, ii/1936, 261.

Calcium Carbide. CaC_2 . Grey masses, becoming white when moist. Evolves acetylene when brought into contact with water. May be used as a test for, and in the preparation of, absolute alcohol. Requires special storage.

Calcium Cyanamide (Prop. Name NITROLIM) is formed when nitrogen is passed over calcium carbide heated to 1000°: $\text{CaC}_2 + \text{N}_2 = \text{CaCN}_2 + \text{C}$. The nitrogen of same interacts with water under pressure, thus:—

$$\text{CaCN}_2 + 3\text{H}_2\text{O} = \text{CaCO}_3 + 2\text{NH}_3$$

The nitrogen must first be freed from oxygen. This is effected by fractional distillation of liquid air. The above method of fixing atmospheric nitrogen is

the Frank-Caro process. Calcium cyanamide is a black powder, containing 15 to 20% nitrogen and about 20% free lime. As a fertiliser it is valuable on acid or "sour" soils and is usually treated with oil to render it granular and to reduce its dusty and corrosive nature.

Calcii Gluconas (*B.P. Add. I*). $C_{12}H_{22}O_{14}Ca, H_2O = 448.3$. Determined on its calcium content by precipitation as oxalate and ignition with sulphuric acid, it contains from 99% to the equivalent of 104% of the pure substance; 5 ml. of the filtrate obtained from 0.5 g. boiled for 2 minutes with 10 ml. of water and 2 ml. of hydrochloric acid, cooled and precipitated with sodium carbonate, gives no reaction for dextrose or sucrose as indicated by no reduction of potassio-cupric tartrate solution, on boiling for 1 minute. *Calcii Gluconas, U.S.P. XII*, dried over sulphuric acid and determined by precipitation with ammonium oxalate and titration with N/10 potassium permanganate, contains 8.8 to 9.3% of Ca corresponding to 99% of the monohydrate.

A tentative method for the determination of calcium gluconate in preparations, the aqueous solutions of which are neutral and do not contain salts of other optically active hydroxy acids, is described in *Methods of Analysis (A.O.A.C., 1940, 617)*.

Calcii Hydroxidum (*B.P. Add. I*). $Ca(OH)_2 = 74.1$. Assayed by digestion with sucrose solution, filtration, and titration of an aliquot part with N/1 hydrochloric acid to phenolphthalein, when it should contain not less than 90% of $Ca(OH)_2$. Aluminium, iron and matter insoluble in hydrochloric acid, not more than 1.0%, the test to be performed on one-half the quantity of substance. The *U.S.P. XII* substance, by precipitation with excess ammonium oxalate in ammoniacal solution and titration of the acidified precipitate of calcium oxalate with potassium permanganate, contains not less than 95% of $Ca(OH)_2$; hydrochloric acid insoluble matter, not more than 0.5%; limit of magnesium, weighed as ignited sulphate, not more than 4.8%.

Liquor Calcii Hydroxidi (*B.P.*). Contains at 15.5° not less than 0.15% *w/v* of $Ca(OH)_2$. Determined by titration with N/10 sulphuric acid using phenolphthalein indicator. The *U.S.P. XII* preparation contains at 25° not less than 0.14% of $Ca(OH)_2$.

Calx Sodica (*U.S.P. XII*). Contains calcium hydroxide and sodium or potassium hydroxide or both. "Low-moisture Soda Lime" contains less than 9% of moisture; "High-moisture Soda Lime" contains 9 to 19%. It may contain an indicator which changes colour when the capacity of the substance for carbon dioxide is exhausted. Tested for loss on drying, moisture absorption and carbon dioxide adsorption capacity.

Calcii Oxidum (*B.P.C.*). $CaO = 56.08$. Loss on ignition not more than 10%. The ignited substance should contain not less than 95% of CaO when determined by the *B.P.* method for *Calcii Hydroxidum*. *Calx, N.F. VII*, loses not more than 10% on ignition to constant weight with a blast lamp, and then contains not less than 95% of CaO. It is assayed by precipitation with excess N/10 oxalic acid in ammoniacal solution and back titration of the acidified filtrate against N/10 potassium permanganate.

CAMPHORA

Camphora (*B.P.*). $C_{10}H_{16}O = 152.1$. Both the synthetic and natural substances are official. M.p., 174° to 177° . Residue on volatilisation not more than 0.05%. The natural and synthetic products, as Camphora, are official in the *U.S.P. XII*; α_D at 25° , of the natural substance in alcohol, $+41^{\circ}$ to $+43^{\circ}$; residue on sublimation, not more than 0.05%; m.p., 175° to 179° . Camphre Artificiel, *Fr. Cx.* 1937, is assayed by weight of the oxime formed with hydroxylamine hydrochloride. The camphoroxime does not melt below 114° . Camphre du Japon, *Fr. Cx.* 1937, should be used for internal use; rotation of 10% solution in absolute alcohol, at 20° , in 2 decimetre tube, about $+8.60^{\circ}$. Camphora and Camphora synthetica are official in the *P.G. VI*; the former melts at 175° to 179° and has a specific rotation for a 20% solution in absolute alcohol of $+44.22^{\circ}$, whilst the latter melts at not lower than 170° and has a specific rotation of -2° to $+5^{\circ}$.

Purity and Assay. The following standard for camphor is recommended by the Sub-Committee on General Organic Chemicals of the Committee on General Chemistry:—Not less than 97% of $C_{10}H_{16}O$. α_D of natural camphor, in a 10% w/v solution in alcohol (95%), $+40^{\circ}$ to $+42^{\circ}$. **Assay.**—Dissolve about 0.2 g., accurately weighed, in 25 ml. of aldehyde-free alcohol (95%) in a 300-ml. flask; add slowly, with constant shaking, 75 ml. of solution of dinitrophenylhydrazine. Heat on a water-bath under a reflux condenser for four hours, allow to cool, dilute to 200 ml. with a 2% v/v solution of sulphuric acid and set aside for twenty-four hours. Collect the precipitate in a tared Gooch crucible fitted with a paper mat, wash with successive quantities of 10 ml. of cold water until the washings are neutral to litmus paper, dry at 80° , and weigh. Each g. of the residue is equivalent to 0.458 g. of $C_{10}H_{16}O$. **Solution of dinitrophenylhydrazine:** dissolve 1.5 g. of 2:4-dinitrophenylhydrazine in 20 ml. of sulphuric acid (50% v/v), dilute to 100 ml. with water and filter. This solution must be freshly prepared.—(*British Pharmacopœia Commission Report*, No. 14, September 1939).

An official quantitative method for the determination of camphor (optically active) is described in *Methods of Analysis (A.O.A.C., 1940, 575)*.

The above process is also recommended by the Sub-Committee on the Assay of Galenicals of the Committee on Pharmaceutical Chemistry for the assay of camphor in spirit of camphor.

Determination with 2:4-Dinitrophenylhydrazine. The following modification of the method of Hampshire and Page (*Quart. J. Pharm.*, 1934, 558) is recommended. 2 ml. of Tinct. Opii Camph. is diluted with 13 ml. of alcohol 90%, 85 ml. of reagent (1.25% of 2:4-dinitrophenylhydrazine dissolved in 10 ml. of sulphuric acid and 10 ml. of water and diluted to 100 ml. with water and filtered) is added slowly. The mixture is heated under a reflux condenser for 4 hours, cooled, diluted to 200 ml. with 2% v/v sulphuric acid and left in the dark for 24 hours. The precipitate is collected, the flask and precipitate washed six times with 10 ml. of water and the precipitate dried at 80° for 1 hour and weighed. 1 g. of the 2:4-dinitrophenylhydrazine is equivalent to 0.458 g. of camphor.—M. M. Janot and M. Mouton, *J. Pharm. Chim., Paris*, 1936, 23, 547.

Colorimetric Determination. 1 ml. of spirit of camphor is mixed with 3 ml. of alcohol 95% and 2 drops of 1% alcoholic furfural solution added, followed by 2 ml. of concentrated sulphuric acid. The mixture is heated on a water-bath for 5 minutes, and the violet colour is compared with that obtained by treating similarly known amounts of camphor. Benzaldehyde may be used instead of furfural, giving a red colour.—A. Castiglioni, per *Quart. J. Pharm.*, 1937, 228.

Creta cum Camphora. The camphor precipitated by pouring an alcoholic solution into water may contain approximately its own weight of water.

Camphorated chalk prepared by the *B.P.C.* method may contain therefore only 9% of camphor. It is advisable that a minimum limit be fixed.—C. L. M. Brown, *Quart. J. Pharm.*, 1937, 402.

Camphoræ Monobromidum (*B.P.C.*) melts between 74° and 76°. Ash, not more than 0.05%.

Official methods for the determination of camphor monobromide in tablets are described in *Methods of Analysis* (*A.O.A.C.*, 1940, 575).

Leptazolium (*B.P. Add. III*). $C_6H_{10}N_4 = 138.1$. M.p., 57° to 60°. Ash, not more than 0.1%.

Microidentification of leptazol in mixed aqueous solutions containing alkaloids and other substances is described.—V. E. Stewart, *Industr. Engng Chem. (anal. Edn.)*, 1939, 345.

Nikethamidum (*B.P. Add. III*). $C_{10}H_{14}ON_2 = 178.1$. Assayed by digestion with 50% *w/v* nitrogen-free sulphuric acid, distillation of the liberated diethylamine into N/10 hydrochloric acid and back titration to methyl red indicator, a blank distillation being performed; it contains not less than 98% of the pure substance. Sp. gr., 1.064 to 1.067. n_{D20° , 1.525 to 1.526.

Oleum Camphoræ Rectificatum (*B.P.C.*). The f.p. of a mixture of 1.5 g. of the oil, 1.5 g. of eucalyptol and 2.1 g. of *o*-cresol is not below 40°, equivalent to not less than 35% of cineole. Sp. gr. 0.875 to 0.900. $\alpha_D + 9^\circ$ to $+24^\circ$. n_{D40° , 1.465 to 1.470.

The two commercial varieties are white camphor oil and brown camphor oil. The former is the early fraction of the natural oil, obtained as a by-product in the manufacture of camphor; the sp. gr. is lower than 0.998. Brown camphor oil is the higher boiling fraction, the sp. gr. varies from 1.000 to 1.040; oil of the higher figure contains a large proportion of safrole, while oil with a gravity in the neighbourhood of 1.000 is the by-product after removal of the safrole by refrigeration. Camphor oil containing a large proportion of safrole and with a specific gravity of about 1.065 is sold as artificial sassafras oil.

CANNABIS

Cannabis (*B.P.C.*). The drug may now be obtained from plants grown in India, Germany, America and South Africa and contains not more than 10% of fruits, large foliage leaves, and stems over 3 mm. in diameter, and not more than 2% of other foreign organic matter. Acid-insoluble ash limit, 5%. Matter soluble in alcohol after drying at 100°, not less than 10%.

Separation of constituents given in the Supplement to the 4th Report of the L. of N. *Alcohol*.—Shake for one hour 5 g. of sample and 100 ml. of petroleum ether. Filter. Place 80 ml. of filtrate in a separator and extract with 50, 30, 30, 20 and 20 ml. portions of N/10 sodium hydroxide. Wash the petroleum ether solution twice with water and add the washings to the alkaline aqueous solution. Filter the petroleum ether solution through cotton into a tared flask, remove the solvent, place in a desiccator for twelve hours and weigh. This gives the alcoholic extract from 4 g. of sample. *Phenol I*.—Extract the alkaline aqueous solution with 100, 75 and 75 ml. portions of ether. To the combined ethereal solutions add 5 ml. of N sulphuric acid, shake, separate and then wash twice with water. Filter into a tared beaker and proceed as for the alcohol. The residue obtained is the amount of phenol I in 4 g. of sample. *Phenol II*.—To the alkaline aqueous solution remaining after extraction with ether add 20 ml. of N sulphuric acid and extract with 100 ml. of ether. Wash

the ether twice with water, filter into a tared flask and proceed as for the alcohol. The residue obtained is the amount of phenol II in 4 g. of sample. *Phenol III*.—Add 25 ml. of petroleum ether to the phenol residues obtained as above and let stand overnight. Decant the solution, wash the undissolved residue twice with petroleum ether, dry in a current of air and place in a desiccator for 12 hours. The residue, which is mainly obtained from the phenol II fraction, is the phenol III obtained from 4 g. of sample. The alcoholic and phenol II fractions are responsible for the biological activity with the alcoholic fraction which is about 55.5% of the total petroleum ether extract. The alcoholic fraction gives an intense alkaline Beam reaction which therefore indicates the presence of the principal constituent of the resin of cannabis which is responsible for its addictive properties. The phenol II fraction gives the acid Beam reaction, but not always the alkaline. Phenol I does not show constant physiological activity, but it is responsible for the optical activity of the resin of cannabis.—F. de Myttenaere, per *J. Amer. pharm. Ass.*, 1939, 355.

Test for Recognition of Hashish : Beam's Test. The suspected material is extracted with petroleum ether of low boiling-point, and the extract filtered and evaporated to dryness. Both extraction and evaporation should be carried out in the cold. In the presence of a considerable quantity of hashish a marked amount of tar-like residue is obtained, but it is sufficient for the reaction if only a faint yellow stain is left. To the residue a weak alcoholic solution of potash or soda (about N/10) is added and the liquid allowed to evaporate at room temperature. In presence of hashish a rich purple or reddish-purple colour develops, which, on dilution with water, takes on a more bluish cast. Hashish is frequently sold dissolved in fat or oil and for such alcohol is best. Extract of Indian hemp and Ceylon samples did not respond. Samples of ganja, charas and majun from India and a plant grown in Egypt responded perfectly. The ordinary hashish sold in Egypt is largely of Greek origin, and of a large number of samples tested since 1909 not one has failed to respond. Soil, climate, cultivation, and curing influence the chemical composition. The following is suggested as a useful presumptive test to which hashish or other cannabis preparations from India, Egypt, Greece, Sudan, and Uganda all respond. The petroleum ether extract is made as usual, and the evaporation of the solvent is carried out in a short test-tube. To the residue is added a few millilitres of reagent prepared by saturating absolute alcohol with dry hydrogen chloride gas. In the presence of cannabis extract the liquid acquires a bright cherry-red colour which disappears on dilution with alcohol or water. Trials were made with a number of plant extracts and over 200 alkaloids, glycosides, etc., but in no case was a similar reaction obtained. Certain volatile oils—e.g., origanum and santal—give a similar reaction, but the colour is far less intense for similar amounts of material.—W. Beam, Wellcome Res. Lab., Khartoum, per *Chem. & Drugg.*, 1916, 12.

The following modification, depending on the phenolic nature of the substance responsible for the coloration, eliminates a number of vegetable substances which give a similar or an interfering colour. The sample is extracted with light petroleum (b.p. 40° to 60°) and the extract filtered into a separating funnel and extracted once or twice with dilute sodium hydroxide solution. The mixed alkaline extracts are acidified and shaken again with successive small quantities of light petroleum. The light petroleum extracts are mixed, the solvent evaporated in a porcelain dish and the residue treated with a saturated solution of hydrogen chloride in dehydrated alcohol. Myrrh and guaiacum are among the very few substances that still interfere.—L. C. Nickolls, *Analyst*, 1936, 604.

Identification of cannabis by Beam's test is not reliable because of the liability to oxidation of the cannabinol during the evaporation of the solution in light petroleum. This is overcome by adding 3 to 4 drops of alcoholic potash, 5%, to 1 ml. of the light petroleum solution of resin, shaking for a minute and adding 1 ml. of amyl alcohol. The final solution varies in colour from pinkish violet to violet-red, according to the amount of active principle present. Samples of the drug and its preparation up to three years old gave strong reaction to the above test, thus contributing to the opinion that cannabinol is not destroyed.—F. de Myttenaere, per *Quart. J. Pharm.*, 1939, 114.

League of Nations Commission on cannabis concluded that the Beam Test and its modification are at present the only tests indicating the biologically active principles and only these principles of cannabis. The great instability of cannabis and its preparation has not been proved. Light petroleum is still

the best solvent for these principles.—F. de Myttenaere, *J. Pharm. Belg.*, 1939, 21, 571, 597 and 615.

Cannabis may be simply and reliably detected by the following tests: A small portion of the drug is placed in a wide-mouthed container with a small excess of a solution containing benzene (nine parts) and sodium hydroxide (2%) in alcohol (one part) and immediately shaken for 5 seconds. The liquid is then immediately decanted into an evaporating dish. The presence of a cannabinol is indicated by a colour change from slightly yellow to pink within one or two minutes, becoming deeper red after standing a short time. Further, spontaneous evaporation of the reddish liquid leaves a pinkish to violet residue which dissolves to an orange-red solution in strong ammonia and to a violet to almost bluish violet solution in acetone.—A. Viehover, *J. Amer. pharm. Ass.* 1937, 589.

Chemistry of the Hemp Drugs.—A. R. Todd, *Nature, Lond.*, ii/1940, 829.

Cannabinol is *l*-hydroxy-3-*n*-amyl-6 : 6 : 9-trimethyl-6-dibenzopyran. Synthesis described.—R. Adams *et al.*, *J. Amer. chem. Soc.*, 1940, 2204.

Cannabidiol has been obtained in crystalline form as long, white rods; m.p., 66°–67°; α_D at 27°, –125°.—R. Adams *et al.*, *J. Amer. chem. Soc.*, 1940, 294.

It would seem that as regards the constituents, Egyptian hemp resin, containing cannabinol and cannabidiol, occupies an intermediate position between American resin, in which cannabinol seems to be absent, and Indian resin from which cannabidiol has not yet been isolated. Cannabidiol gives a positive Beam test, but is physiologically inactive, thus supporting the view that this test is not specific for the active principle of hashish. A new constituent of Indian hemp has also been isolated and named cannabool. It gives a negative Beam test, but a positive indophenol reaction. It seems probable that it is a partially hydrogenated cannabinol, isomeric with cannabidiol.—A. Jacob and A. R. Todd, *Nature, Lond.*, i/1940, 350.

Determination of Physiological Activity of Hemp Resin. The activity of charas, ganja and bhang (for descriptions of these terms see Vol. I, p. 353) is associated with their resins, but the resin content is not a measure of potency. There is a definite relationship between the specific rotation of the drug and its physiological activity, and a polarimetric method has been devised for its assay. The specific rotation of the resin of good and fresh charas is about –105° whilst that of older and inferior material is as low as –64°; that of ganja of good quality is about –90°, and of inferior quality about –60° or less.—M. N. Ghose and S. W. Bhattacharjee, *Analyst*, 1935, 313.

Extractum Cannabis. This material is sometimes submitted to a biological test by administering doses of a soft extract, equal to 0.25 g., to one or two cats. The extract is given in gelatin capsules which are placed at the back of the mouth and so readily swallowed. Active extracts produce some intoxication and inco-ordination of movement; most striking is the inclination to stay for several seconds in an awkward posture. The effect may last for 3 or 4 hours.

CANTHARIS

Cantharis (B.P.C.). Foreign organic matter, not more than 2%. Moisture, not more than 10%. Cantharis, in powder, is adjusted, by the addition of powder of higher or lower cantharidin content, to contain not less than 0.6% of cantharidin. It is assayed by maceration with chloroform acidified with hydrochloric acid, filtration and evaporation of an aliquot part; after removal of the fat with light petroleum the insoluble residue is treated with N/1 sodium hydroxide and warmed with 5% potassium permanganate solution; the mixture is made strongly acid with 40% sulphuric acid, chloroform and ferrous sulphate are added, and the cantharidin extracted with chloroform; the residue, after evaporation of the chloroform, is finally weighed after drying at 65°. Cantharis, *N.F. VII*, yields not more than 10% of moisture and not less

than 0.6% of cantharidin, by extraction with a mixture of benzene, petroleum ether and hydrochloric acid at 40°; after evaporation of the solvent from an aliquot part, followed by evaporation with chloroform, the residue is washed with a mixture of absolute alcohol and petroleum ether saturated with cantharidin, dissolved in chloroform, evaporated, and dried at 60° for 30 minutes. Cantharides, *P.G. VI*, should yield not less than 0.7% of cantharidin determined by maceration for 24 hours with chloroform and hydrochloric acid (20 : 1), addition of ether and filtration. From an aliquot part most of the solvent is evaporated and the remainder spontaneously, the residue treated with 10 ml. of petroleumbenzene and absolute alcohol (19 : 1), shaken occasionally for 12 hours, the crystalline residue treated with 5 ml. of benzene-alcohol mixture, dissolved in chloroform, evaporated, dried and weighed. Further treatment is necessary if the cantharidin is not crystalline. Cantharis, *P. Helv. V*, contains not less than 0.7% of cantharidin, and the powder when prescribed except for plasters is adjusted with lactose to contain 0.6%. Assayed by refluxing 10 g. with 100 g. of benzene and 1 g. of hydrochloric acid for 30 minutes; 81 g. of filtrate (= 8 g. drug) is evaporated to 5 g. and dried on a water-bath at 60° in a current of dried air. The residue is treated with 10 ml. of petroleum ether absolute alcohol mixture (19 : 1), the crystals collected, dissolved in chloroform, evaporated spontaneously and dried over sulphuric acid.

The following modified process of Self and Greenish is recommended for the assay of cantharidin in cantharides:—Triturate 10 g. in moderately coarse powder with 1 ml. of HCl and exhaust completely in a continuous extraction apparatus with 100 ml. of CHCl_3 . Distil or evaporate off the CHCl_3 and remove the last traces by a current of air. Boil the residue under a reflux condenser with 70 ml. of H_2O and filter immediately through a small moistened filter paper in a warmed separator. Return the fat and filter to the flask and boil for 5 minutes with 50 ml. H_2O ; repeat twice with 50 ml. and 40 ml. of water respectively. Cool the mixed aqueous extract, add 2 ml. of HCl and extract with 30, 25 and 20 ml. of CHCl_3 , wash the CHCl_3 with 10 ml. of H_2O , remove the CHCl_3 and dry the residue in a current of air at 60°. Wash the residue with 3 lots of 5 ml. each of a mixture of 3 parts of light petroleum and 1 part of absolute alcohol previously saturated with cantharidin, dry the residue of cantharidin at 60° and weigh.—G. A. Guthrie and H. Brindle, *Quart. J. Pharm.*, 1942, 61.

Cantharidinum (B.P.). $\text{C}_{10}\text{H}_{12}\text{O}_4 = 196.1$. M.p., 216° to 218°. Ash, not more than 0.1%. Cantharidin in preparations containing it may be detected by the following process:—To 20 ml. of the liquid add sufficient H_2SO_4 to make it slightly acid and extract 3 or 4 times with chloroform. Evaporate the CHCl_3 to about 2 to 3 ml., add 0.2 ml. of a vegetable oil such as sesame or cottonseed, evaporate and dry at 100° to remove the CHCl_3 . Apply to the skin on a very small pad of lint (the lint should be saturated with the oil) and leave in contact for about 12 hours. If cantharidin is present, a blister will form or the skin be much reddened. Taking 20 ml. of a liquid, the test will show 5 to 10 parts of cantharidin per million. If a larger volume is taken the test may, of course, be made still more delicate.

CAPSICUM

Capsicum (B.P.). Contains not more than 3% of calices and pedicels, not more than 1% of stalks and foreign organic matter, and yields not more than 7% of ash. Capsicum, *N.F. VII*, contains not more than 3% of stems and calyces and not more than 1% of other foreign organic matter; non-volatile ether-soluble extractive, not less than 12%; acid-insoluble ash, not more than 1.25%. In the *N.F. VII* the botanical sources of Capsicum are given as *Capsicum frutescens* (African Chillies), *Capsicum annuum* var. *conoides* (Tabasco Pepper), *Capsicum annuum* var. *longum* (Louisiana Long Pepper) and a hybrid between the Honka variety of Japanese Capsicum and Old Louisiana Sport Capsicum (Louisiana Sport Pepper).

Pungency Test. The following test for pungency of capsicum is recommended by the Sub-Committee on Crude Drugs of the Committee on Pharmacy and Pharmacognosy:—Macerate 1 g., accurately weighed, in moderately coarse powder, with 50 ml. of alcohol (95%) shaking continuously for six hours or frequently during twenty-four hours, and filter. Dilute 6 ml. of the filtrate to 100 ml. with water. Dilute 1 ml. of this solution to 50 ml. with a 5% solution of sucrose in water; 3 ml. of this solution, swallowed all at once produces a distinct sense of pungency in the throat of at least two out of three individuals.—(*British Pharmacopæia Commission Report*, No. 13, September 1939.)

The Food and Drug Administration of the U.S. Dept. of Agriculture defined cayenne pepper, cayenne, as the dried, ripe fruit of *Capsicum frutescens* L., *C. baccatum* L., or some other small-fruited species of *Capsicum*. Required to contain not less than 15% of non-volatile ether extract, not more than 1.5% of starch, not more than 28% of crude fibre, not more than 8% of total ash, nor more than 1.25% of ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

Extraction of Capsaicin and its Colorimetric Determination. 100 g. of oleoresin (*U.S.P. X*, extracted with ether) is mixed thoroughly with twice its volume of liquid paraffin and shaken out with three successive 200 ml. portions of alcohol (57%). The mixed alcoholic extracts are shaken with 100 ml. of liquid paraffin, the alcoholic layer is separated and the alcohol distilled off. The cooled aqueous residue is extracted with ether, emulsification being prevented by the addition of sodium chloride. The ether is removed by distillation, and the oily residue is boiled for 10 minutes, with occasional stirring, with 4 g. of lithium hydroxide (carbonate-free) and 200 ml. of water. After standing overnight carbon dioxide is passed intermittently through the mixture for two hours, water being added if it becomes too thick, and it is again allowed to stand overnight. The precipitate is collected, washed and dried at a low temperature. The precipitate and filter are boiled under a reflux condenser with 500 ml. of light petroleum for 15 to 20 minutes, the hot light petroleum decanted on to a filter and the clear filtrate set aside below 0° to crystallise. The crystals are rapidly filtered and transferred to a securely stoppered vial. The first precipitate and the filters should be re-extracted with light petroleum. At least 5 g. of capsaicin is obtained from 100 g. of oleoresin of Mombasa capsicums. It has a m.p. of 64°, and its acidity is detectable in a dilution of 1:10,000,000.

Determination. The determination depends on the production of an intense blue colour with vanadium oxychloride. A 2% w/v extract of capsicum (dried overnight in a desiccator) prepared by maceration for 30 to 60 minutes in dry acetone, or a 0.2% solution of the oleoresin in dry acetone is prepared, and also a standard 0.02% solution of capsaicin coloured with an acetone extract of capsaicin-free paprika to match the test solution. Standard tubes are prepared with from 1.5 ml. upwards of capsaicin solution diluted with coloured acetone to 5 ml. To each tube is added one drop of a 1% w/v solution of vanadium oxychloride in carbon tetrachloride for each thousandth part per cent. of capsaicin present. The reagent is then added drop by drop to the unknown until no deepening in colour is observed; excess must be avoided since the colour changes to green. The colour slowly fades after the reaction.—*L. F. Tice, Amer. J. Pharm. 1933 320.*

A study of the oxytrichloride colorimetric method for the determination of capsaicin in capsicum led to the following conclusions: (1) The maceration period of 30 to 60 minutes is sufficient to extract the capsaicin from capsicum using acetone as the solvent. (2) The duration of the reliable colour in the standard is not long enough to ensure satisfactory matching with the unknowns. (3) A permanent non-fading colour for the standard may be achieved by using colorimetric solutions of cupric sulphate and ferric chloride. (4) More concordant results are obtained by using a weaker solution of the vanadium oxytrichloride (0.5% prepared volumetrically), and measuring the reagent from a graduated pipette on a burette instead of using the dropper method. (5) A number of substances containing phenolic compounds gave colour reactions with the reagent. In some instances the colours produced approximated the standard so closely that a colour test using vanadium oxytrichloride would not serve as a reliable qualitative or quantitative test for capsaicin.—A. Hayden and C. B. Jordon, *J. Amer. pharm. Ass.*, 1941, 107.

Oleoresin of Capsicum. The so-called oleoresins of capsicum vary in appearance, solubility and degree of pungency according to the solvent used for extraction.

Oleoresin of capsicum, *B.P.C.*, is prepared by extracting an ether oleoresin with alcohol (90%) and is soluble in ether, alcohol (90%), acetone, benzene, chloroform, petroleum spirit, fixed oils and turpentine. It has a greater pungency value than any of the other oleoresins of capsicum, the pungency being about three or four times that of oleoresin of capsicum, *B.P.C.*, '23, which was extracted with alcohol (60%).—H. Berry, *Quart. J. Pharm.*, 1935, 479.

CARBO

Carbo. (B.P.C.). Ash, not more than 7%. Moisture, not more than 15%. *Carbo Activatus, U.S.P. XII*, loses not more than 15% at 120°; ash, not more than 4%; acid-soluble substances, not more than 3.5%; tests for adsorptive power using strychnine sulphate solution, methylthionine chloride and sodium sulphide are included; a test for heavy metals is included. *Carbo Animalis Purificatus, N.F. VII*, loses not more than 12% at 100° for 2 hours; hydrochloric acid-soluble impurities, not more than 6%; tests for adsorptive power with methylene blue and with N/10 iodine are included.

A test for activity of medicinal and other charcoals by exposure to water and other vapours. Active charcoal will absorb 50 to 100%, or even more, of moisture. The water figure is slightly higher than that for alcohol or turpentine. *Pulv. Carbo. Lig.* as ordinarily dispensed for medicinal purposes is inactive. The author suggests improvements in the manufacture, and the adoption in the *B.P.* of tests for activity.—H. Brindle, *Pharm. J.*, ii/1928, 84.

Astonishing variety in the potency of different brands. A comparison of the adsorptive powers of thirty samples (using methylene blue as the substance to be adsorbed) showed coefficients varying from 85 to 0.5.—N. Mutch, *Brit. med. J.*, i/1934, 320.

Tests for Purity. The following tests for purity for medicinal charcoal are recommended by the Sub-Committee on Ointments and Miscellaneous Galenicals of the Committee on Pharmacy and Pharmacognosy:—It adsorbs from solution not less than 30% of its weight of phenazone and adsorbs completely from solution 10% of its weight of strychnine hydrochloride, both calculated with reference to its activated charcoal previously heated to 110°. A black, odourless and tasteless powder, free from gritty particles. Unchanged when heated in the absence of air. When burnt in air or oxygen, forms carbon dioxide and carbon monoxide. When heated with sulphuric acid, evolves carbon dioxide and sulphur dioxide. The Tests for Purity should include the following:—When heated, gives off no foreign odour (absence of adsorbed vapours). Boil 1 g. with 50 ml. of water for five minutes under a reflux condenser, cool, filter, and reject the first 15 ml. of the filtrate; 25 ml. of the filtrate

requires for neutralisation not more than the 0.2 ml. of either N/10 sulphuric acid or N/10 sodium hydroxide, solution of bromothymol blue being used as indicator (limit of alkalinity or of acidity). Boil 0.25 g. with 10 ml. of solution of sodium hydroxide and filter; the filtrate is colourless. Boil 0.5 g. with 25 ml. of dilute hydrochloric acid; the vapour evolved does not blacken lead paper (limit of sulphide). Boil 1.5 g. for five minutes with 100 ml. of water under a reflux condenser; cool, filter, and reject the first 15 ml. of the filtrate:—10 ml. of the filtrate complies with the limit test for chlorides; 30 ml. of the filtrate complies with the limit test for sulphates. Add 5 g. to a solution of 2 g. of tartaric acid in 50 ml. of water contained in a distillation flask. Attach the flask to an efficient condenser with the outlet dipping below the surface of 10 ml. of N/1 sodium hydroxide, and distil about 25 ml. To the liquid in the receiver add 2 ml. of solution of ferrous sulphate and then acidify with hydrochloric acid: no blue colour or precipitate is produced (absence of cyanogen compounds). Boil 1 g. with a mixture of 20 ml. of dilute hydrochloric acid and 5 ml. of solution of bromine for five minutes; filter, and wash the residue with 50 ml. of boiling water; evaporate the filtrate and washings to dryness and treat the residue with a mixture of 1 ml. of N/1 hydrochloric acid, 20 ml. of water and 5 ml. of solution of sulphurous acid; boil until all the sulphur dioxide is expelled and dilute to 50 ml. with water; the solution complies with the following tests:—10 ml. shows no change of colour within ten seconds when 5 ml. of solution of hydrogen sulphide is added. 10 ml. boiled with 0.3 ml. of nitric acid, again boiled with excess of dilute solution of ammonia, and filtered, if necessary, gives only a slight discoloration with 5 ml. of solution of hydrogen sulphide within ten seconds, and no turbidity within two minutes (limit of heavy metals). Loses, when heated at 110°, not more than 10% of its weight. Leaves, on ignition, not more than 4% of residue. *Assay*.—For adsorptive power. Add about 0.3 g. accurately weighed, to 50 ml. of a 0.4% solution of phenazone in a stoppered flask, and shake at frequent intervals for twenty minutes. Filter through a dry filter paper and reject the first 15 ml. of the filtrate. To 25 ml. of the filtrate in a stoppered flask add 2 g. of sodium acetate and 30 ml. of N/10 iodine and shake occasionally for twenty minutes. Add 10 ml. of chloroform, shake until the precipitate is dissolved and titrate the excess of iodine with N/10 sodium thiosulphate. Repeat the process, omitting the activated charcoal. The difference between the two titrations corresponds to the amount of iodine required for the phenazone adsorbed by the activated charcoal. Each ml. of N/10 iodine is equivalent to 0.009405 g. of phenazone. For complete adsorptive power. Shake the equivalent of 1 g. of the activated charcoal dried at 110° with 50 ml. of a 0.2% solution of strychnine hydrochloride in water for five minutes, filter through a dry filter paper, and reject the first 15 ml. of the filtrate; 10 ml. of the filtrate gives no turbidity or precipitate on the addition of 0.5 ml. of dilute hydrochloric acid and 0.5 ml. of solution of potassium-mercuric iodide.—(*British Pharmacopæia Commission Report*, No. 13, September 1939).

Carboni Dioxidum (*B.P. Add. I*). $\text{CO}_2 = 44.00$. By measurement of the volume adsorbed when passed into 50% *w/v* potassium hydroxide solution at N.T.P. it contains not less than 99% *v/v* of CO_2 . 500 ml. (at N.T.P.) is passed through 50 ml. of sodium bicarbonate solution and then through 80 ml. of water with 4 drops of methyl orange; a further 500 ml. is passed directly through one-half of this solution, when the colour should not differ from that of the other half (limit of acid and sulphur dioxide). In the limit test for phosphine, hydrogen sulphide and organic reducing substances, silver ammonio-nitrate solution is replaced by a mixture of silver nitrate and dilute ammonia solution and water. The *U.S.P. XII* fixes the same standard and assays similarly. 1000 ml. passed through 50 ml. of recently boiled and cooled distilled water, under specified conditions, renders it not more acid to methyl orange than 1 ml. of N/100 hydrochloric acid. Carbon monoxide is excluded by shaking 1000 ml. with diluted blood and adding a mixture of pyrogallol and tannic acid.

The grey colour obtained is matched against that produced in a blank test using 1000 ml. of carbon monoxide-free carbon dioxide.

Carbon Monoxide in Industry.

This gas occurs when any organic matter is burnt in a restricted amount of air and hence is a component of town gas (6 to 9%) and the exhaust gases of motor engines. It is also one of the components in producer or water gas (25 to 50%) and carburetted water gas (30%). Considerable amounts of carbon monoxide are liberated when explosives are detonated and in war-time there is grave risk of poisoning in camouflages, where bombs have exploded underground, and which are filled with carbon monoxide under pressure. It is colourless, odourless and non-irritant and herein lies its chief danger, since often the first warning of its presence may be inability to move. Its poisonous action is due to its power of combining with the hæmoglobin of the blood, forming a compound which is not decomposed by oxygen. Its affinity for hæmoglobin is about 250 times that of oxygen, and hence in the presence of both gases the partition of hæmoglobin is strongly in favour of combination with carbon monoxide. Thus, as the absorption of carbon monoxide by the blood proceeds the supply of oxygen to the blood progressively decreases.

Table of Permissible Concentrations of CO in Air.

| | |
|---|----------------|
| Allowable for exposure of several hours | 0.01% |
| Allowable for exposure of one hour without appreciable effect | 0.04 to 0.05% |
| Causing just appreciable effect after one hour | 0.06 to 0.07% |
| Causing unpleasant but not dangerous symptoms after one hour | 0.1 to 0.12% |
| Dangerous for exposure of one hour | 0.15 to 0.2% |
| Fatal in exposure of less than one hour | 0.4% and over. |

—V. Henderson and F. W. Haggard, per *Lancet*, i/1933, 154.

Treatment. Remove patient into fresh air at once, keep him lying down and warm, and apply artificial respiration, keeping it up steadily for hours if necessary. Give inhalations of oxygen with 5 to 7% carbon dioxide. Methylene blue, 50 ml. of 1% solution intravenously, said to be of value. Stimulants such as hot black coffee. Nikethamide, 5 to 15 ml. of 25% solution intravenously, said to be useful. Venesection not to be recommended as it withdraws healthy as well as poisoned blood and weakens the patient, but blood transfusion has sometimes saved life. Saline infusion. The patient should be kept quiet for several days and carefully watched in case fresh symptoms appear.

Detection and Determination. The most satisfactory method for detecting and determining carbon monoxide in the air is by the use of palladium chloride. A 0.5% solution of palladium chloride in distilled water is filtered bright and mixed with an equal volume of A.R. acetone. Pieces of filter paper are soaked in the mixed reagent, pressed very lightly to expel excess solution, and known volumes of the suspected air drawn through by means of a pump or by a glass bottle aspirator. In order to remove hydrocarbons, especially when exhaust fumes are suspected, the air is

drawn through a tube containing activated carbon, before being passed through the treated filter paper, carbon monoxide not being absorbed by charcoal. A grey to black colour denotes the presence of carbon monoxide, owing to the reduction to palladium, and according to the volume of air filtered and the depth of colour the amount of CO in the air can be determined. It is inadvisable to keep the palladium chloride solution mixed with acetone, and the filter papers must be prepared immediately before use.—(*Toxic Gases in Industry*, No. 7, D.S.I.R.)

Phosgene in Industry.

Phosgene or carbonyl chloride (COCl_2) is usually considered to be one of the most powerful lung irritant war gases, but it is also used as an intermediate in several chemical processes and hence the risk is not restricted to chemical warfare. It may also occur as the result of incomplete combustion of organic solvents, used as fire extinguishers, such as carbon tetrachloride and trichlorethylene. It is commonly stated to smell like musty hay, but many forms of over-ripe vegetation, such as freshly cut sour apples, resemble it closely. It is a colourless gas, boiling at 8.2°C . and is, therefore, non-persistent. One of the most unfortunate aspects of poisoning by this gas is that there may be slight coughing, lachrymation and tightness of the chest at first, but that these soon pass off, leaving the patient with a feeling of well-being, to be followed later by a severe collapse, due to severe oedema of the lungs, though the face may not appear fully cyanosed as with most lung irritants. For prolonged exposure the greatest possible concentration is 1 part in 1,000,000, whilst 1 part in 200,000 for half an hour may prove fatal eventually. It is readily absorbed by activated carbon and decomposed by many chemical agents such as water, alkalis and hexamine.

Detection and Determination. Apart from the odour, phosgene is most readily detected by the development of a yellow to deep orange colour on a paper impregnated with a solution containing 5% each of *p*-dimethylaminobenzaldehyde and diphenylamine in absolute alcohol, and dried. The colour developed may be compared with standard colour charts.—(*Toxic Gases in Industry*, No. 8, D.S.I.R.)

Carbonei Disulphidum (B.P.C.). $\text{CS}_2=76.12$. Sp. gr., 1.268 to 1.272; residue on evaporation at 100° , not more than 0.01%; boiling range, 95% between 46° and 47° .

The B.S.S. No. 662—1936 includes requirements for specific gravity (1.270 to 1.274 at 15° and 1.265 to 1.269 at 20°), boiling range (not less than 95% below 46.4°), residue on evaporation and acidity, and a test for absence of hydrogen sulphide.

Detection in the Atmosphere. Samples of the air under examination are bubbled through a mixture of 10 ml. of absolute alcohol, 2 ml. of solution (a) containing 2 ml. of diethylamine in 100 ml. of benzene, and 2 ml. of solution (b) containing 0.1 g. of copper acetate in 100 ml. of absolute alcohol. After standing, the colour developed is compared with a series of standards of known strengths of carbon disulphide.—(*Toxic Gases in Industry*, No. 6, D.S.I.R.)

CARDAMOMUM

Cardamomum (B.P.). Separated from the fruits when required for use, and contains not more than 3% of foreign organic matter. Ash, not more than 6%. *Cardamomi Semen*, *U.S.P. XII*, should be recently removed from the capsules and yield not more than 4% of acid-insoluble ash.

The *B.P.* limit of impurity should apply to the fruit and not to the seed, which must not be separated from the fruit until required for use and is therefore protected from adulteration.—*Pharm. J.*, ii/1932, 68.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined cardamom as the dried, nearly ripe fruit of *Elettaria cardamomum* Maton. Cardamom seed was defined as the dried seed of cardamom. Required to contain not more than 8% of total ash, nor more than 3% of ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

Oleum Cardamomi (B.P.C.). Sp. gr., 0.923 to 0.945; α_D^{20} , +20° to +44°; n_{D20° , 1.461 to 1.467. Ester value, 90 to 156. It should be soluble in 4 volumes of alcohol (70%, sp. gr. 0.8896 to 0.8901). *Oleum Cardamomi, N.F. VII*, has a sp. gr. at 25° of 0.917 to 0.947. Rotation in a 100 mm. tube at 25°, +22° to +44°.

The husks are for practical purposes inert. The green cardamoms yield more oil than the bleached. Imported decorticated seeds yield less oil than those recently removed from the husk. Loss of oil from the husk-protected seed on keeping over eight months is small; decorticated seeds lost 80% of oil on keeping over the same period. The oil requires not less than three hours for saponification.—Clevenger, *J. Ass. off. agric. Chem., Wash.*, 1934, 283.

CARUM

Carum (B.P.). Limits: for foreign organic matter, 2%; for ash, 9%; for acid-insoluble ash, 1.5%. *Carum, U.S.P. XII*, contains not more than 3% of other fruits, seeds or foreign organic matter; acid-insoluble ash, not more than 1.5%. *Fructus Carvi, P.G. VI*, must yield not less than 4% of volatile oil.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined caraway, caraway seed, as the dried fruit of *Carum carvi* L. Required to contain not more than 8% of total ash or more than 1.5% of ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

Oleum Cari (B.P.). Assayed by the same method as for *Oleum Anethi, B.P. '32*, it contains from 53 to 63% *w/w* of carvone. Sp. gr., 0.910 to 0.920. α_D^{20} , +70° to +80°. n_{D20° , 1.485 to 1.492. Soluble in one volume of alcohol (90%, sp. gr. 0.8334 to 0.8340) and in 7 volumes of alcohol (80%, sp. gr. 0.8634 to 0.8640). *Oleum Cari, N.F. VII*, should contain not less than 50% *v/v* of carvone; estimated by measurement of the oil remaining after treatment with sodium sulphite. n_{D20° , 1.484 to 1.488.

Determination of carvone in caraway oil.—Bennett and Cocking (*Quart. J. Pharm.*, 1931, 580) give a method of applying the hydroxylamine reaction.

Caraway oil consists mainly of carvone, sp. gr. 0.964, and limonene, sp. gr. 0.846; the sp. gr. of the oil is therefore a good indication of the proportion of carvone.

CARYOPHYLLUM

Caryophyllum (B.P.). Clove should contain not more than 5% of its stalks and not more than 1% of foreign organic matter. Limits: ash, 10%; acid-insoluble ash, 0.75%. Tests for limit of stalks and absence of clove fruits and cereals are included. Caryophyllus, *U.S.P. XII*, should yield not less than 16% *v/w* of volatile oil and not more than 10% of crude fibre; the limits for stem, foreign organic matter and acid-insoluble ash are the same as in the *B.P.* Flores Caryophylli, *P.G. VI*, should yield not less than 16% of volatile oil. Flos Caryophylli, *P. Helv. V*, should yield not less than 16% of essential oil; ash, not more than 7%; acid-insoluble ash, not more than 1%.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined cloves as the dried flower-buds of *Caryophyllus aromaticus* L. Contains not more than 5% of clove stems, not less than 15% of volatile ether extract, not less than 12% of quercitannic acid (calculated from the total oxygen absorbed by the aqueous extract), not more than 10% of crude fibre, not more than 7% of total ash, and not more than 0.5% of ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

The export of cloves from Zanzibar is controlled by a Clove Growers' Association. There are standards for three different grades and each bale or package must be up to the standard for the particular grade.—*Perfum. essent. Oil Rec., 1934, 239.*

Oleum Caryophylli (B.P.). By difference from the volume of the oil unabsorbed by potassium hydroxide solution, a eugenol content of not less than 85% and not more than 90% *v/v* should be indicated. Sp. gr., 1.047 to 1.060. n_{D20}° , 1.528 to 1.537. Soluble in 2 volumes of alcohol (70%, sp. gr. 0.8896 to 0.8901). Oleum Caryophylli, *U.S.P. XII*, should contain not less than 82% *v/v* of eugenol, the absorption of the eugenol with potassium hydroxide being effected during 10 minutes at the temperature of the water-bath. The optical rotation should not exceed $-1^{\circ} 30'$ in a 100 mm. tube at 25° ; n_{D20}° , 1.5300 to 1.5350; hot water shaken with the oil is only very faintly acid and on cooling shows no blue or violet colour of phenol with 1 drop of ferric chloride solution. Essence de Girofle, *Fr. Cx. 1937*, by extraction with petroleum ether, transferring to sodium hydroxide, acidifying and extracting with ether, contains not less than 70% of eugenol.

Emulsification of the oil in the assay with caustic potash can be prevented by pretreating the oil with a paste of tartaric acid and then drying over anhydrous sodium sulphate.—P. A. Rowan and J. A. Insinger, *Chem. Weekbl.*, 1939, 36, 642.

Clove oil may contain up to 20% of acetyl-eugenol, which is hydrolysed so easily that it appears as eugenol in the assay for phenols.

Oils having a eugenol content of more than 90% are obtainable but are less fragrant.—C. T. Bennett, *Pharm. J.*, i/1933, 150.

Oil of clove roots. The yield of oil is about 6% from the roots; the eugenol content is high.—*Chem. & Drugg.*, i/1923, 136. Oil distilled from clove stems is also usually high in eugenol.

Eugenol (B.P.C.). $C_{10}H_{12}O_2 = 164.1$. Sp. gr., 1.072 to 1.074; n_{D20}° , 1.541 to 1.542. Eugenol, *U.S.P. XII*, has a sp. gr. at 25° of 1.064 to 1.070 and boils between 250° and 255° ; n_{D20}° , 1.540 to 1.542; optically inactive.

Oleum Myrciæ (B.P.C.). Contains not less than 45% of phenols. Sp. gr., 0.945 to 0.990; α_D , 0° to 4°; n_{D20} , 1.500 to 1.520. Estimated by the B.P. method for eugenol in Oleum Caryophylli. The N.F. VII oil should yield 50 to 65% v/v of phenols, as indicated by the potassium hydroxide absorption; rotation, laevorotatory but not exceeding -3° in a 100 mm. tube at 25°; sp. gr., 0.950 to 0.990 at 25°.

Pimenta (B.P.C.). Yields not more than 6% of ash.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined allspice, pimento, as the dried, nearly ripe fruit of *Pimenta officinalis* Lindl. Required to contain not less than 8% of quercitannic acid (calculated from the total oxygen absorbed by the aqueous extract), not more than 25% of crude fibre, not more than 6% of total ash or more than 0.4% of ash insoluble in hydrochloric acid.—S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.

Oleum Pimentæ (B.P.C.). Eugenol content, determined as for Oleum Caryophylli, not less than 60% v/v; sp. gr., 1.035 to 1.057; α_D , 0° to -5°; n_{D20} , 1.500 to 1.536. Oleum Pimentæ, N.F. VII, should contain 65% v/v of phenols. Sp. gr. at 25°, 1.018 to 1.048; α_D , at 25°, 0° to -4°. The presence of clove oil may be detected by the test for furfuraldehyde, *vide* test under Ol. Menth. Pip.

CASCARA SAGRADA

Cascara Sagrada (B.P.). Foreign organic matter, not more than 2%. Ash, not more than 6%. The U.S.P. XII allows 4% of foreign organic matter, and for medicinal preparations it should be collected one year before use.

The larger proportion of anthraquinone derivatives in cascara are in the combined form. The U.S.P. fluid extract contained 0.4%. Fluid extracts of commerce contained 0.17 and 0.24%. Debittered cascara contained 0.07%.—J. Amer. pharm. Ass., 1926, 847.

The characteristic aperient action is not due to emodin. Emodin is, however, a constituent, but chrysophanic acid or chrysarobin could not be found. Apparently there are no chemical differences between one and three years' old ("matured") bark. Storage was said to exhaust a ferment and to moderate the gripping action which the fresh bark possesses. No relation between the emodin content and the physiological action.—J. D. v. d. Graaf, *Pharm. Weekbl.*, 1932, 753.

The following test for identity of cascara bark is recommended by the Subcommittee on Crude Drugs of the Committee on Pharmacy and Pharmacognosy:—Moisten 0.2 g., in powder, with 1 ml. of alcohol (95%), add 10 ml. of water, and shake for fifteen minutes, boil, cool and filter. Shake the filtrate with 10 ml. of ether; a yellow ethereal solution separates on standing. Shake 3 ml. of the ethereal solution with 3 ml. of dilute solution of ammonia and to the separated aqueous liquid add 20 ml. of water; the mixture retains a characteristic yellowish-red colour (distinction from frangula bark).—(*British Pharmacopæia Commission Report*, No. 13, September 1939.)

A tentative method for the determination of cascara sagrada is described in *Methods of Analysis* (A.O.A.C., 1940, 595).

Substitutes. The bark from Texas, Arizona, Colorado, and New Mexico is sometimes substituted by or mixed with the bark of *Rhamnus Californica*, which is of a greyer tint externally, and the transverse section is less dark and more yellow than *R. Purshiana*. An inferior variety, known as Winter Bark, is cut from the steamed branches and is therefore in the form of chips.—*Chem. & Drugg.*, i/1925, 560.

CHLORALIS HYDRAS

Chloralis Hydras (B.P.). $\text{CCl}_3 \cdot \text{CH}(\text{OH})_2 = 165.4$. Should contain not less than 99% of the pure substance. Assayed by addition of excess of N/1 sodium hydroxide, standing for 2 minutes, and back titration with N/1 sulphuric acid to phenolphthalein. Ash, not more than 0.05%. The *U.S.P. XII* requires a purity of 99.5%.

Assay. The following process for the assay is recommended by the Subcommittee on Synthetic Chemicals:—Dissolve about 4 g., accurately weighed, in 10 ml. of water, and add 30 ml. of N/1 sodium hydroxide. Allow the mixture to stand for two minutes, and titrate with N/1 sulphuric acid, using solution of phenolphthalein as indicator. Titrate the neutralised liquid with N/10 silver nitrate, using solution of potassium chromate as indicator. To the amount of N/1 sulphuric acid used in the first titration, add one-tenth the amount of N/10 silver nitrate used in the second titration, and deduct the figure so obtained from that of the N/1 sodium hydroxide added. Each ml. of N/1 sodium hydroxide represented by the difference is equivalent to 0.1654 g. of $\text{C}_2\text{H}_3\text{O}_2\text{Cl}_3$.—(*British Pharmacopœia Commission Report*, No. 11, May 1939.)

B.P. assay is unsatisfactory due to the hydrolysis of the chloroform produced by the action of the sodium hydroxide. The following method is recommended. Introduce about 0.5 g. of chloral hydrate into a Kjeldahl flask with the aid of 20 ml. of neutral alcohol. Add accurately 25 ml. of 2N alcoholic potash solution and boil gently under reflux for half an hour. Remove the flame, wash the condenser with 15 to 20 ml. of alcohol and boil gently for a further half an hour. After cooling, titrate the mixture with N/2 or N/1 acid to phenolphthalein.—T. L. Bowyer, *Chem. & Drugg.*, ii/1939, 343.

Chloralformamidum (B.P.C. Supp. V). $\text{C}_3\text{H}_4\text{O}_2\text{NCl}_3 = 192.4$. M.p., 116° to 122° . Volatilises without evolving inflammable vapours and leaves not more than 0.01% of residue.

Butylchloralis Hydras (B.P.C.). $\text{C}_4\text{H}_9\text{O}_2\text{Cl}_3 = 193.4$. Ash, not more than 0.05%. Tests for limit of chloride and of chloral hydrate are described.

Chlorbutol (B.P.). $\text{C}_4\text{H}_7\text{OCl}_3 = 177.4$. M.p., not below 78° . M.p. of the anhydrous substance, 96° . Ash, not more than 0.1%. The majority of samples melt slightly below the B.P. minimum. Chlorobutanol, *U.S.P. XII*, should not melt below 76° .

Alcohol Trichlorisobutylicus, *P. Helv. V*, is $\text{C}_4\text{H}_7\text{OCl}_3 \cdot \frac{1}{2}\text{H}_2\text{O}$, and, without previous drying, melts between 79.5° and 81° . It is assayed as follows:—Dissolve about 1 g. in 20 ml. of alcohol and dilute to 100 ml. with water. Transfer 10 ml. to a 200 ml. flask, add 0.5 ml. of 30% sodium hydroxide solution, 10 ml. of alcohol and heat on a water-bath just to boiling. Allow to cool, add 0.5 ml. of concentrated nitric acid, dilute with 50 ml. of water, neutralise with excess of calcium carbonate and titrate the mixture to potassium chromate with N/10 silver nitrate. A blank experiment is also prescribed. Each ml. of N/10 silver nitrate is equivalent to 0.0062147 g. of $\text{C}_4\text{H}_7\text{OCl}_3 \cdot \frac{1}{2}\text{H}_2\text{O}$.

Determination. To avoid the difficulties caused by the presence of organic materials (as in suppositories) the material should be first steam-distilled, the distillate being collected in N/2 potassium hydroxide in propyl alcohol. If the material is alkaline, excess boric acid is added first. The distillate is refluxed for one hour, evaporated in a nickel crucible to dryness, ignited and the chlorine assayed argentimetrically.—G. Vastogh, *Pharm. Zentrall.*, 1937, 78, 498.

Tentative methods for the determination of chlorbutol crystals and of solutions of chlorbutol are described in *Methods of Analysis (A.O.A.C., 1940, 602)*.

CHLORAMINA

Chloramina (B.P.). $\text{C}_7\text{H}_7\text{O}_2\text{NCISNa} \cdot 3\text{H}_2\text{O} = 281.6$. Contains from 98% to the equivalent of 103% of the pure hydrated

compound. Assayed by interaction with potassium iodide in acidified solution for 10 minutes, followed by titration of the liberated iodine with sodium thiosulphate; 1 ml. of N/10 thiosulphate is equivalent to 0.01408 g. of $C_7H_7O_2NCISNa, 3H_2O$. Chloramina-T, *U.S.P. XII*, should contain from 11.5 to 13% of active chlorine, assayed by digestion with potassium iodide in acetic acid solution. 1 ml. of N/10 thiosulphate is equivalent to 0.001773 g. of active chlorine; 0.2 g. complies with a test for carbonisable substances. Chloramine-T, *Fr. Cx. 1937*, contains 24 to 26% of chlorine. Natrium sulfaminochloratum, *P. Helv. V*, contains 24 to 26% of active chlorine.

Chloramine-T has been suggested to replace the more expensive iodine solution in analytical processes.—*J. chem. Soc. Abstr.*, ii/1925, 66.

Carbasus Chloraminæ (B.P.C.). Contains from 4 to 6% of $C_7H_7O_2NCISNa, 3H_2O$.

Dichloramina (B.P.C.). $C_7H_7O_2NCl_2S = 240.0$. Determined by titration of the iodine liberated from potassium iodide in acetic acid solution, it contains not less than 93% of $C_7H_7O_2NCl_2S$; 1 ml. of N/10 thiosulphate is equivalent to 0.006001 g. of $C_7H_7O_2NCl_2S$. Dichloramina-T, *N.F. VII*, should contain not less than 28% and not more than 30% of active chlorine.

CHLOROFORMUM

Chloroformum (B.P.). $CHCl_3 = 119.4$. Sp. gr., 1.485 to 1.490. Usually not more than 15% *v/v* distils below 60°, the remainder distilling between 60° and 62°. Limit of residue on evaporation, 0.004% *w/v*. Tests for acidity, chloride, free chlorine, hydrochloric acid, foreign organic matter, foreign chlorine compounds, decomposition products and aldehyde are included. Chloroformum, *U.S.P. XII*, leaves not more than 0.002% *w/v* of residue, dried at 100°; it contains from 99 to 99.5% of $CHCl_3$. Sp. gr. at 25°, 1.474 to 1.478. Chloroforme Anesthésique, *Fr. Cx. 1937*, should contain 0.5% of alcohol; determined by shaking with sulphuric acid, dilution and distillation, finally titrating with a solution of potassium dichromate. Chloroformum ad narcosin, *P. Helv. V*, is required to be of a higher degree of purity than Chloroformum which is administered in solution; two independent series of control tests are prescribed for these substances.

Determination. Colorimetric determination of small quantities in solution (0.1 to 0.0001%) in animal tissues. A pink colour is obtained on heating a solution with pyridine in presence of sodium hydroxide.—*W. H. Cole, J. biol. Chem.*, 1926, 71, 173.

Chloroform in various mixtures and galenicals may be determined colorimetrically by means of the colour reaction that it gives with β -naphthol in strong potassium hydroxide solution. 10 ml. of 2% *w/v* solution of β -naphthol in 40% cold potassium hydroxide solution is measured in a series of Nessler tubes, measured volumes of a 0.5% standard solution of chloroform in 95% industrial methylated spirit, and sufficient industrial methylated spirit to make the total volume measure 11 ml. are added; the tubes are shaken and allowed to stand

for 5 to 10 minutes, and the colours compared by means of a Dubosq colorimeter. If the colours are compared within a few minutes, good results are obtained.—W. G. Moffitt, *Analyst*, 1933, 2.

Chloroform may be determined in mixtures free from other chlorine compounds (other than chlorides which may be determined and subtracted from the results obtained). Distil the chloroform from a flask containing the mixture and alcohol with a little calcium carbonate into alcoholic potash until about three-quarters of the original volume has been distilled. Allow the alcoholic potash and distillate, after shaking well, to stand in a closed vessel overnight, acidify and determine the chloride by titration with excess silver nitrate, filtration, and back titration with ammonium thiocyanate.

Tentative methods for the determination of chloroform in mixtures are described in *Methods of Analysis (A.O.A.C., 1940, 602)*.

Tests for Phosgene. To 15 ml. of medicinal chloroform (which contains alcohol) in a dry stoppered bottle add 20 mg. each of resorcinol and vanillin. Close the bottle and, when the reagents are dissolved, place it in the dark for 1 hour. Add 5 ml. of 1% aqueous ammonia, shake, and allow to separate. In presence of phosgene or hydrochloric acid a pink or red colour develops in the aqueous layer, reaching a maximum in 30 seconds.—N. L. Allport, *Analyst*, 1931, 706.

Mix with a 1% solution of *p*-dimethylaminobenzaldehyde and diphenylamine in acetone. In the presence of 0.01% of phosgene a yellow colour develops in 15 minutes.—L. Rosenthaler, *Pharm. Acta Helvet.*, 1937, 6.

Aqua Chloroformi (B.P.). A 0.25% solution of chloroform in distilled water. The U.S.P. XII water is a saturated solution and is approximately twice the strength.

Linimentum Chloroformi (U.S.P. XII). Contains at 25°, 27 to 35% *v/v* of CHCl_3 , determined by a standardised fractional distillation method.

Trichloroethylenum (U.S.P. XII). Contains 99 to 99.5% of C_2HCl_3 , the remainder consisting of alcohol. Sp. gr. at 25°, 1.456 to 1.462, B.pt. 86° to 88°, non-volatile residue, dried at 110°, not more than 0.002%. 20 ml. should be equivalent to not more than 0.5 ml. N/100 sodium hydroxide in a test in which phenolphthalein is used as indicator. Tests for free chlorine and chloride ion are included.

Determination. Trichloroethylene is quantitatively hydrolysed by heating with 25% aqueous potassium hydroxide in a sealed Carius tube for 1 hour at 150°. The ratio by weight of potassium hydroxide to trichloroethylene should be 2 or 3 to 1 (i.e., 8 to 12 ml. of the hydroxide solution per g. of trichloroethylene present). Potassium chloride is formed in amount equivalent to the total chlorine present and is determined by the Volhard method.—D. F. Kelly, M. O'Connor and J. Reilly, *Analyst*, 1941, 489.

A British Standard Specification (B.S.S. No. 580—1934) has been issued by the British Standards Institution for trichloroethylene (technical and stabilised). The specification includes requirements regarding description, specific gravity (1.469 to 1.475 at 15.5°), distillation range, residue on evaporation, acidity, free chlorine and sampling, and the appendices describe the methods and apparatus to be used.

Tetrachlorethylene. Determination in mixtures.—*Methods of Analysis (A.O.A.C., 1940, 604)*.

Test. Warm 2 drops with 5 drops of 10% sodium hydroxide solution and 10 drops of pyridine, the pyridine layer assumes a strong red colour.—B. Samdahl, and H. Sansaker, *Norsk. farm. Tidsskt.*, 1938, 46, 31, 46.

Carbonei Tetrachloridum (B.P.). $\text{CCl}_4 = 153.8$. Sp. gr., 1.603 to 1.606; boiling-range, 76.5° to 77.5°. Residue on evaporation on a water-bath, not more than 0.002% *w/v*. The U.S.P. XII substance after evaporating nearly to dryness on a water-bath and then spontaneously, followed by drying at 100°, leaves not more than 0.002% *w/v* of residue.

A British Standard Specification (B.S.S. No. 575—1934) has been issued by the British Standards Institution for carbon tetrachloride. The specification includes requirements regarding description, specific gravity, distillation-range, residue on evaporation, acidity, oxidisable impurities, free chlorine, sulphur

compounds and sampling, and the appendices describe the methods and apparatus to be used.

The proportion of carbon disulphide in benzene, carbon tetrachloride and other liquids can be found colorimetrically by means of diethylamine and a copper salt. One part in 1,000,000 parts of benzene can be detected.—T. Callan, J. A. R. Henderson and N. Strafford, *J. Soc. chem. Ind., Lond.*, 1932, 193.

Tentative methods for the determination of carbon tetrachloride in mixtures or capsules are described in *Methods of Analysis (A.O.A.C., 1940, 603)*.

Hexachlorethane. A British Standard Specification (*B.S.S. No. 577—1934*) has been issued by the British Standards Institution for hexachlorethane. The specification includes requirements regarding description, melting-range (183° to 187°), moisture, matter insoluble in alcohol, ash, acidity and alkalinity, grading and sampling, and the appendices describe the methods and apparatus to be used.

Diphenanum (B.P.C. Supp. III). $C_{14}H_{13}O_2N = 227.1$. Contains not less than 99.5% of the pure substance, determined by digestion with 50% nitrogen-free sulphuric acid and distillation of the ammonia produced. M.p., 146° to 150° . Loss at 100° , not more than 0.2%. Ash, not more than 0.1%.

Iodoformum (B.P.). $CHI_3 = 393.8$. Should contain 99% of CHI_3 . Assayed by digestion overnight with alcohol (95%), N/10 silver nitrate and nitric acid, dilution, and back titration with N/10 ammonium thiocyanate. M.p., 120° to 122° . Ash limit, 0.2%. The *N.F. VII* specifies that Iodoformum should lose not more than 1% on drying over sulphuric acid for 24 hours, and leave not more than 0.2% of ash. Iodoformum, *P. Helv. V*, is assayed by a methyl alcohol and silver nitrate process similar to that following; it contains 99.3% of CHI_3 .

Assay. The following assay for iodoform is recommended by the Subcommittee on General Organic Chemicals of the Committee on General Chemistry:—Dissolve about 0.5 g., accurately weighed, in 50 ml. of alcohol (95%) and add 50 ml. of N/10 silver nitrate and 5 ml. of nitric acid. Boil under a reflux condenser for thirty minutes, cool, add 150 ml. of water, and titrate with N/10 ammonium thiocyanate, using solution of ferric ammonium sulphate as indicator. Each ml. of N/10 silver nitrate, precipitated by the iodide formed, is equivalent to 0.01313 g. of CHI_3 .—(*British Pharmacopœia Commission Report*, No. 14, September 1939).

An official method for the determination of iodoform in iodoform ointment is described in *Methods of Analysis (A.O.A.C., 1940, 619)*.

Carbasus Iodoformi (B.P.C.). The iodoform, extracted with alcohol and titrated as Iodoformum, should be equivalent to from 4 to 6%.

CHROMII TRIOXIDUM

Chromii Trioxidum (B.P.). $CrO_3 = 100.0$. Contains not less than 95% of CrO_3 . Determined by oxidation of potassium iodide in solution, acidified with dilute sulphuric acid, and titration with N/10 sodium thiosulphate, using starch mucilage as indicator. Water-soluble matter after ignition, not more than 2%. The *U.S.P. XII* requires a purity of 98%, using hydrochloric acid to acidify the titration liquid.

Potassii Dichromas (B.P.C.). $K_2Cr_2O_7 = 294.2$. Assayed with potassium iodide and N/10 sodium thiosulphate, it contains not less than 99% of pure salt.

CHRYSAROBINUM

Chrysarobinum (B.P.) Ash, not more than 0.5%. The U.S.P. XII fixes an ash limit of 0.3%.

Dithranol (B.P. Add. VI). $C_{14}H_{10}O_3 = 226.1$. M.p., 174° to 178° . Ash, not more than 0.1%. Loss at 100° , not more than 1%. A test for absence of dihydroxanthraquinone is included.

CINCHONA

(with CINCHONA ALKALOIDS)

Cinchona (B.P.). Contains not more than 2% of other organic matter, and not less than 6% of total alkaloids of which not less than one half is quinine and cinchonidine. Ash, not more than 4%. *Assay* (B.P. '32 process): The powdered bark is mixed with strong solution of lead subacetate and water and allowed to stand; after standing with ammoniacal alcohol, it is subjected to continuous extraction with more ammoniacal alcohol; the alcohol is recovered, and the residue treated with successive portions of sulphuric acid and water until completely extracted; the filtered aqueous shakings, cleaned by shaking with chloroform, are made alkaline with ammonia and the alkaloid extracted with chloroform, dried at 100° and weighed. The total alkaloids are then dissolved in water, N/1 sulphuric acid and alcohol, and the boiling liquid made just pink to hæmatoxylin with N/10 sodium hydroxide. The acidified and filtered boiling liquid is concentrated, sodium potassium tartrate added, and set aside for 24 hours to crystallise; the alkaloidal tartrates are decomposed with sodium hydroxide and finally extracted with chloroform, evaporated, and the residue of quinine and cinchonidine dried at 100° and weighed. Cinchona, N.F. VII, should contain not less than 5% of alkaloids, determined by heating with hydrochloric acid and water, cooling, macerating with ether, chloroform and stronger ammonia solution; followed by extraction of an aliquot part with 5% sulphuric acid, finally rendering ammoniacal and extracting with chloroform.

Quinquina Jaune, Fr. Cx. 1937, contains not less than 6% of total alkaloids and Quinquina Rouge, not less than 5%. Assayed by digestion with dilute hydrochloric acid and water, shaking with soda and ether-chloroform and clarifying with tragacanth, evaporating an aliquot and titrating with N/10 hydrochloric acid to methyl red.

Cortex Chinæ, P.G. VI, is the bark of *Cinchona succirubra* Pavon, and should yield not less than 6.5% of alkaloid by the process prescribed. Cortex Cinchonæ, P. Helv. V, is the bark of cultivated *Cinchona succirubra* Pavon, containing not less than 6.5% of alkaloids; and yields not more than 6% of ash and not less than 15% of water-soluble extractive.

Percolation of a moderately fine powder (44/85) gave better extraction of both alkaloids and total solids, when compared with percolation of either a fine powder (85) or a moderately coarse powder (22/60). This indicates that an optimum degree of comminution exists for percolation of cinchona. The

relative percentage of alkaloids to other solids increases in successive fractions of percolate.—A. W. Bull, *Quart. J. Pharm.*, 1935, 378.

For a comparison of the results given by the B.P. assay process with those given by the methods of some other pharmacopœias see P. A. W. Self and C. E. Corfield, *Quart. J. Pharm.*, 1930, 410. The B.P. assay processes for cinchona galenicals are based on a further paper by the same authors (*Quart. J. Pharm.*, 1931, 335).

A method of extraction has been suggested in which the drug is percolated with boiling alcohol, first in the presence of potassium hydroxide then during the addition of alcoholic hydrochloric acid and finally in the presence of excess of hydrochloric acid. The extraction is said to be complete in two hours. The results for total alkaloids are usually lower than by the official method, but it is claimed that this is due to obtaining a purer residue of alkaloids.—N. L. Allport and D. Friend, *Quart. J. Pharm.*, 1938, 450.

Alpha-Naphthol Test for Cinchona Alkaloids. Added to an aqueous solution of quinine sulphate, a few drops of fresh saturated alcoholic alpha-naphthol solution to which a few drops of concentrated sulphuric acid (2 drops per ml.) have been added, produce a yellow precipitate; when the reagent is in excess a yellow solution results. Quinidine, cinchonidine and cinchonine sulphates act likewise; no other white alkaloids appear to give this reaction. Cinchona alkaloids can thus be detected in presence of atropine, morphine, cocaine, strychnine, caffeine, brucine, codeine and antipyrine. A drop of the reagent added to chloroform or ether residues of any of the cinchona alkaloids gives a yellow colour.—Watson, *Amer. J. Pharm.*, 1913, 502; *Pharm. J.*, ii/1913, 881.

"Grey" cinchona bark from Huanuco found to contain quinine 0.45%, cinchonidine 0.22%, cinchonine 0.63%, amorphous alkaloid 0.48%.

A further sample of S. American bark contained 5.49% of cinchonine and only 0.027% of quinine. It consisted of *C. nitida* and other varieties, and was also "grey" bark. The abnormal content of cinchonine probably due to cultivation or growth at low altitudes and in hot moist atmosphere.—B. F. Howard and O. Chick, *Yearb. Pharm.*, 1920, 385.

Approximate determination as used by the planters for *C. Ledgeriana*. Extract with ether, using slaked lime and sodium hydroxide. Dissolve residue in ether and N/HCl, and titrate with N/NaOH, using litmus. Precipitate tartrates of quinine and cinchonidine, filter, wash, dry and weigh. Determine optical rotation, α , and calculate quantity of quinine and cinchonidine from Cammellin's table. To the filtrate from the tartrates add NaI solution to precipitate quinidine, cinchonine and amorphous alkaloids. Separate quinidine with 94% alcohol.—*Yearb. Pharm.*, 1923, 8.

Extractum Cinchonæ (B.P.). Determined by dilution with alcohol and water, extraction of the acidified liquid with chloroform, making alkaline with sodium hydroxide solution, extraction with chloroform, finally drying at 100° and weighing. Contains 9.5 to 10.5% of alkaloids.

Extractum Cinchonæ Liquidum (B.P.). Contains 4.75 to 5.25% w/v of alkaloids of Cinchona.

Tinctura Cinchonæ (B.P.). Contains 0.95 to 1.05% w/v of alkaloids of Cinchona.

Tinctura Cinchonæ Composita (B.P.). Contains 0.475 to 0.525% w/v of alkaloids. The N.F. VII tincture contains 0.4 to 0.5% w/v of alkaloids of cinchona. Assayed by absorption and shaking with ether-chloroform (4:1) and ammonia solution, followed by extraction of an aliquot with dilute acid, finally transferring to chloroform with ammonia and weighing the alkaloid after evaporation of the solvent.

Tinctura Cinchonæ Composita Concentrata (B.P. Add. V). Determined by the process for Extractum Cinchonæ after evaporation, it contains 1.9 to 2.1% w/v of alkaloids of Cinchona.

Æthylhydrocupreinae Hydrochloridum (B.P.C.).

$C_{21}H_{28}O_2N_2 \cdot HCl = 376.7$. By extraction with chloroform from ammoniacal solution, evaporation, and drying at 100° , it contains not less than 90% of $C_{21}H_{28}O_2N_2$. The *N.F. VII* substance also contains 90% of the base. Æthylhydrocupreinum basicum and Æthylhydrocupreinum hydrochloridum are official in the *P. Helv. V* and each contains not less than 99% of the pure substance.

Cinchonidinae Sulphas (B.P.C.). $(C_{19}H_{22}ON_2)_2 \cdot H_2SO_4 \cdot 7H_2O = 812.6$. Loss at 100° , not more than 16%. Ash, not more than 0.1%. A limit test for quinine, cinchonine and quinidine is described. The salt of the *N.F. VII* is the trihydrate which should lose not more than 12% at 100° .

Cinchonidine sulphate, though very soluble, forms a double compound with quinine sulphate and so always crystallises with the quinine to some extent.—G. E. Shaw, Streatfeild Memorial Lecture, 1934.

Cinchoninae Hydrochloridum (B.P.C.). $C_{19}H_{22}ON_2 \cdot HCl$, $2H_2O = 366.7$. Loss at 100° , not more than 10%. Ash limit, 0.1%.

Cinchoninae Sulphas (N.F. VII). $(C_{19}H_{22}ON_2)_2 \cdot H_2SO_4 \cdot 2H_2O = 722.9$. Loss at 100° , not more than 5%.

Quinetum (B.P.C.). Yields not less than 60% of quinine and cinchonidine, and loses not more than 5% at 100° . Ash, not more than 1%. Assayed by the *B.P.* method for Totaquina.

The Malaria Commission of the League of Nations recommended (1932) that quinetum should be the name applied to a mixture of quinine, cinchonidine and cinchonine in equal parts, this being approximately the proportion in which the alkaloids occur in *Cinchona succirubra*. Of three commercial samples, only one met this specification.—J. A. Goodson and T. A. Henry, *Quart. J. Pharm.*, 1932, 161.

Totaquina (B.P.). Should contain not less than 70% of crystallisable alkaloids of which at least one-fifth is quinine. On drying for one hour at 70° and then at 100° , the loss is not more than 5%. Ash, not more than 5%. *Assay (B.P. '32 process)*: a boiling solution of 2 g. in 20 ml. of N/1 sulphuric acid, 40 ml. of water and 40 ml. of 95% alcohol, made just alkaline to litmus with N/10 sodium hydroxide, is cooled and made just acid, boiled and filtered; the filtrate is evaporated to 120 g., 30 g. of sodium potassium tartrate added and stood for 24 hours. The precipitate, collected on a hardened filter, is washed with 80 ml. of 25% sodium potassium tartrate solution, decomposed with sodium hydroxide and extracted with chloroform; the proportion of quinine in this residue of quinine and cinchonidine is estimated by a methoxyl determination, by interaction with hydriodic acid, passing the methyl iodide into silver nitrate and weighing as AgI. The filtrate and washings from the precipitated tartrate are made alkaline with sodium hydroxide and extracted with ether, the alkaloid transferred to acid and the cinchonine precipitated by running into ether and N/1 sodium hydroxide; the precipitate, collected on a weighed filter, is washed with the ether from the filtrate and with two further ether shakings of the aqueous solution, and finally dried at 100° , adding a correction for solubility in ether. The separated ethereal layer of the filtrate is extracted

with 10% *w/w* solution of glacial acetic acid, the boiling solution neutralised with dilute ammonia, 5 g. of potassium iodide added and stood overnight. The precipitate, washed with 50% alcohol, is dried at 100°, weighed as quinidine hydriodide and corrected for loss due to solubility. The *U.S.P. XII* substance contains not less than 10% of anhydrous quinine, not less than 25% of cinchonidine and anhydrous quinine combined, and a total of not less than 70% of cinchonidine, cinchonine, anhydrous quinidine, and quinine. Ash, not more than 6%. *Totaquina, Fr. Cx.* 1937, contains not less than 70% of crystallisable alkaloids of which not less than 15% is quinine and not more than 20% is amorphous alkaloids; ash, not more than 5%; loss at 100°, not more than 5%. Assayed for quinine and cinchonidine by precipitation with sodium potassium tartrate (a solubility correction is added), the proportion of quinine being found by methoxyl determination. For the determination of cinchonine the alkaloid, recovered from the tartrate filtrate, is dissolved in 15 to 25 ml. of alcohol (96%) diluted with an equal volume of water and after 24 hours filtered and dried at 105° (correction for each ml. alcohol = 0.001 g.). Quinidine is precipitated as iodide (correction = 0.0008 g. for each ml. alcohol).

Assay of Totaquine. In the *U.S.P. XII* assay, quinine and cinchonidine are separated as tartrates which are dried and weighed. Quinine is determined in the precipitate by dissolving 0.5 g. in 3.8 ml. of N/1 hydrochloric acid and sufficient distilled water to produce 25 ml. The solution is slowly inverted 3 times with 20 mg. of activated charcoal and filtered immediately through a dry filter into a dry flask. The first few ml. are rejected and the optical rotation of the filtrate is determined in a 200 mm. tube at 25° using sodium light. The percentage of anhydrous quinine is calculated from the following formula:—

$$\frac{(M - 322) \times 0.79 \times T}{2.02 \times S}$$

M = observed angular rotation *n* minutes, T = weight of dried tartrate precipitates and S = weight of totaquine taken for the assay. The separation of cinchonine and quinidine is essentially the same as that in the *B.P.* process.

Alternative assay processes for *Totaquina* Type I (made direct from the bark of *C. succirubra*) and Type II (made from residues of quinine extraction and adjusted by the addition of quinine) are described.—*Quart. Bull. Hlth Org. L. o. N.*, 1934, 3, 339.

A tentative method for determination of cinchona alkaloids is described in *Methods of Analysis (A.O.A.C., 1940)*. The total alkaloids (about 0.5 g.) dissolved in 50 ml. of 0.225N sulphuric acid are heated on a steam-bath for 10 minutes, 5% sodium hydroxide added until a faint permanent precipitate is produced, sufficient 0.225N sulphuric acid to clear and a further 5 ml. added and then 25 ml. of a Rochelle salt solution (100 ml. of saturated solution with 3 ml. of 0.225N sulphuric acid). After allowing to remain at 10° to 15° for 2 hours, with occasional stirring, the precipitate is washed with 40 ml. of Rochelle salt solution and water (equal parts). The tartrates are decomposed with warm 10% sulphuric acid and extracted with ammonia and chloroform. The proportions of quinine and cinchonidine in the dried residue are determined by dissolving in 0.225N sulphuric acid (1 ml. for each 0.015 g. of alkaloid) and reading the angular rotation produced, using the longest tube possible and a bichromate filter. The proportion of quinine (Q) is calculated from the formula, $Q = (-68.44) (a + 2.7)$; *a* = the observed rotation in a 100 mm. tube. For quinidine the acid tartrate solutions are heated on a steam-bath for 10 minutes, 0.5 g. of potassium iodide added and kept at 10° to 15° for 2 hours. The precipitate is washed with 15 ml. of ice water and dried at 100° for 1 hour. The filtrate and washings made ammoniacal are extracted with chloroform and the cinchonine dried at 100° for 1 hour.

Reaction for Distinguishing Quinine from Quinidine. Inasmuch as quinine and quinidine are optical isomers, most of their reactions are identical. Thirty commonly used alkaloidal reagents give the same test with both. The differentiating test is as follows: To a solution of the pure alkaloid in very dilute sulphuric acid add a drop of $KI \cdot I_2$ solution, shake, and dilute, if the precipitate is heavy, until a light translucent suspension is obtained. In the case of quinine the precipitate appears dark brown while if the sample is quinidine it will appear yellow.—L. Rossi and J. A. Sozzi, per *Amer. J. Pharm.*, 1935, 491.

Quinidina (B.P.C.). $C_{20}H_{24}O_2N_2 \cdot 2H_2O = 360.2$. Loss at 100° , not more than 10%. Ash, not more than 0.1%.

Quinidinæ Sulphas (B.P.). $(C_{20}H_{24}O_2N_2)_2 \cdot H_2SO_4 \cdot 2H_2O = 782.5$. Loss at 120° , not more than 5%. Ash, not more than 0.04%. It is tested for other cinchona alkaloids by precipitating as iodide and adding ammonia to the filtrate, when no turbidity should be produced. The *U.S.P. XII* allows the same moisture limit and 0.1% of ash; 0.2 g. complies with a test for carbonisable substances.

Chinidinum sulfuricum, *P. Helv. V*, should contain 99.5% of $(C_{20}H_{24}O_2N_2)_2 \cdot H_2SO_4 \cdot 2H_2O$. Other cinchona alkaloids are excluded by the following tests:—(a) Dissolve 5 g. of quinidine sulphate in 10 ml. of water, add 0.5 g. of potassium iodide and maintain the liquid for 1 hour at 15° , shaking strongly and frequently; filter through a glass filter and add 2 drops of 3.4% *w/v* solution of ammonia; no cloudiness should be produced either immediately or within 1 hour. (b) The rotation of a solution of 0.391 g. in 0.8 ml. of 7.3% *w/v* hydrochloric acid and 20 ml. of water, at 20° and in a 200 mm. tube, should be between $+10.5^\circ$ and $+10.7^\circ$.

Tabellæ Quinidinæ Sulphatis (U.S.P. XII). Contain 94 to 106% of the labelled amount of $(C_{20}H_{24}O_2N_2)_2 \cdot H_2SO_4 \cdot 2H_2O$, including all tolerances. Assayed by macerating a weighed quantity of powdered tablets with water and dilute sulphuric acid overnight, filtering, making alkaline an aliquot of the filtrate with ammonia solution, extracting with chloroform, filtering the combined chloroform extracts, removing the chloroform, evaporating the residue with alcohol and drying at 100° .

QUININE AND ITS SALTS

The following table shows the principal *B.P.* and *B.P.C.* standards for quinine and the salts of quinine. All, with the exception of Quininæ et Æthylis Carbonas, are required to comply with the *B.P.* test for limit of other cinchona alkaloids. The quantities which are directed to be taken for the test are given in the fourth column of the table. The specified quantity of the substance with 50 ml. of water and 5 ml. of dilute sulphuric acid is made ammoniacal with 5 ml. of dilute solution of ammonia and extracted with 30 ml. and then 20 ml. of chloroform, each being washed with two 10 ml. quantities of water; most of the chloroform is evaporated, about 3 ml. of dehydrated alcohol added and quickly evaporated. The opaque residue is dissolved in 20 ml. of alcohol and 20 ml. of water, and 1 ml. of a methyl red solution added; at 75° the solution is adjusted with *N/5* sulphuric acid to the same colour as 56 ml. of solution of *pH* 5.44 at 20° , with 1 ml. of the methyl red solution; the mixture is evaporated to

| Substance | Percentage of Anhydrous Quinine | Maximum % loss on drying | Quantity to be taken in "other cinchona alkaloids" test | Maximum % of ash |
|--|---------------------------------|-------------------------------|--|------------------|
| Quinina (<i>B.P.C.</i>) $C_{20}H_{24}O_2N_2 \cdot 3H_2O = 378.3$ | not less than 85 | 15 at 100° | 1.1 g. (in 20 ml. of 90% alcohol commencing with addition of 20 ml. of water and methyl red) | 0.05 |
| Quininæ Acetylsalicylas (<i>B.P.C.</i>) $C_{20}H_{24}O_2N_2 \cdot C_8H_8O_4 = 504.3$ | not less than 63.5 | 1 at 100° | 1.5 g. | 0.05 |
| Quininæ Arsenas (<i>B.P.C.</i>) $(C_{20}H_{24}O_2N_2)_3 \cdot H_3AsO_4 \cdot 8H_2O = 934.5$ | not less than 69 | 16 at 100° | 1.4 g. | — |
| Quininæ Benzozas (<i>B.P.C.</i>) $C_{20}H_{24}O_2N_2 \cdot C_6H_5O_2 = 446.3$ | 72 to 75 | — | 1.4 g. | 0.1 |
| Quininæ Bisulphas (<i>B.P.</i>) $C_{20}H_{24}O_2N_2 \cdot H_2SO_4 \cdot 7H_2O = 548.4$ | about 59 | 24 at 110° | 1.7 g. (in 50 ml. water without addition of acid) | 0.04 |
| Quininæ Citras (<i>B.P.C.</i>) $(C_{20}H_{24}O_2N_2)_3 \cdot C_6H_5O_7 \cdot 7\frac{1}{2}H_2O = 1800$ | not less than 74.5 | 10.5 at 100° | 1.3 g. | 0.1 |
| Quininæ Dihydrobromidum (<i>B.P.C.</i>) $C_{20}H_{24}O_2N_2 \cdot 2HBr \cdot 3H_2O = 540.1$ | not less than 59 | 11 at 100° | 1.7 g. | 0.1 |
| Quininæ Dihydrochloridum (<i>B.P.</i>) $C_{20}H_{24}O_2N_2 \cdot 2HCl = 397.1$ | about 81 | 3 at 110° | 1.2 g. | 0.04 |
| Quininæ Disalicylsolicylas (<i>B.P.C.</i>) $C_{20}H_{24}O_2N_2 \cdot C_{18}H_{16}O_{10} = 840.4$ | 38 to 40 | — | 2.5 g. | — |
| Quininæ et Ethylis Carbonas (<i>B.P.</i>) $C_{21}H_{21}O_2N_2 \cdot CO_2 \cdot C_2H_5 = 396.2$ | — | 2 over H_2SO_4 for 24 hours | — | 0.04 |
| Quininæ et Ureæ Hydrochloridum (<i>B.P.C.</i>) $C_{20}H_{24}O_2N_2 \cdot CH_4N_2O_2 \cdot 2HCl \cdot 5H_2O = 547.3$ | not less than 58 | 16.5 at 100° | 1.7 g. | 0.1 |

| Substance | Percentage of Anhydrous Quinine | Maximum % loss on drying | Quantity to be taken in other cinchona alkaloids' test | Maximum % of ash |
|---|---------------------------------|--------------------------|--|------------------|
| Quininæ Glycerophosphas (B.P.C.) (C ₂₀ H ₃₄ O ₄ N ₂), C ₂ H ₅ O ₄ P, 4H ₂ O = 892.6 | not less than 70 | 8.5 at 100° | 1.4 g. | — |
| Quininæ Hydriodidum (B.P.C.) C ₂₀ H ₃₄ O ₄ N ₂ ·HI = 452.1 | not less than 71 | 1 at 100° | 1.4 g. | 1.0 |
| Quininæ Hydrobromidum (B.P.C.) C ₂₀ H ₃₄ O ₄ N ₂ ·HBr, 2H ₂ O = 441.2 | not less than 73 | 9 at 100° | 1.3 g. | 0.1 |
| Quininæ Hydrochloridum (B.P.) C ₂₀ H ₃₄ O ₄ N ₂ ·HCl, 2H ₂ O = 396.7 | about 82 | 10 at 110° | 1.2 g. | 0.04 |
| Quininæ Hypophosphis (B.P.C.) C ₂₀ H ₃₄ O ₄ N ₂ ·H ₃ PO ₃ , 2H ₂ O = 426.3 | not less than 74 | 9 at 100° | 1.3 g. | — |
| Quininæ Lactas (B.P.C.) C ₂₀ H ₃₄ O ₄ N ₂ ·C ₃ H ₅ O ₂ = 414.3 | not less than 72 | 3 at 100° | 1.3 g. | 0.1 |
| Quininæ Phosphas (B.P.C.) (C ₂₀ H ₃₄ O ₄ N ₂) ₃ ·2H ₃ PO ₄ , 6H ₂ O = 1277 | 74 to 78 | 10 at 100° | 1.3 g. | — |
| Quininæ Salicylas (B.P.C.) C ₂₀ H ₃₄ O ₄ N ₂ ·C ₇ H ₅ O ₃ ·H ₂ O = 480.3 | not less than 67 | 4 at 100° | 1.4 g. | 0.1 |
| Quininæ Sulphas (B.P.) (C ₂₀ H ₃₄ O ₄ N ₂) ₃ ·H ₂ SO ₄ ·7½H ₂ O = 881.6 | about 73.5 to 76.5 | 11 to 16 at 100° | (On the substance dried at 50° for 2 hours commencing with 1 g. boiled with 30 ml. of water) | 0.04 |
| Quininæ Tannas (B.P.) | 30 to 35 | 10 at 100° | 3.3 g. (after preliminary treatment) | 0.3 |
| Quininæ Valerianas (B.P.C.) C ₂₀ H ₃₄ O ₄ N ₂ ·C ₄ H ₁₀ O ₃ ·H ₂ O = 444.3 | not less than 71 | — | 1.4 g. | 0.1 |

dryness on a water-bath and powdered, 1 g. boiled with 30 ml. of water under a reflux condenser, is cooled rapidly to 15°, shaking vigorously, and maintained at that temperature, with frequent shaking, for 30 minutes, and filtered rapidly. 6.5 ml. of solution of ammonia (10.0 to 10.2% *w/w* NH_3) at 15° is added all at once to 5 ml. of the clear filtrate at 15° and on mixing gently a clear liquid should be produced. Quininæ Tannas is extracted, before applying this test, with ether from a sodium hydroxide, ether and tragacanth mixture, the ethereal liquid being then extracted with sulphuric acid.

Quininæ Sulphas, *U.S.P. XII*, is the dihydrate. The moisture, determined at 100°, is not more than 5%. The test for "other cinchona alkaloids" described for the sulphate and used, after preliminary treatments, for the other *U.S.P. XII* quinine salts, differs slightly in detail from the *B.P.* test. 1.8 g. of the salt dried at 50° is shaken for 30 minutes with 20 ml. of water at 65°, macerated for 2 hours at 15° and filtered; 5 ml. of the filtrate produces a clear mixture with 6 ml. of ammonia solution (10 to 10.2%). 0.2 g. of quinine salts complies with the test for readily carbonisable substances except in the case of Quininæ Hydrochloridum *U.S.P. XII*, where the amount used is 0.1 g. and 2 ml. of sulphuric acid is used in place of 5 ml.

Chininum sulfuricum, *P. Helv. V*, is the stable dihydrate, $(\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2)_2 \cdot \text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, and contains from 4.5 to 4.7% of water. The absence of other cinchona alkaloids is ensured by the following tests:—(a) Dissolve 0.85 g. of the quinine sulphate in 50 ml. of boiling water in a tared flask; cool rapidly and shake well, and make up to 51 g. with water; add 5 g. of powdered potassium sulphate and keep at 20° for 30 minutes, shaking frequently and strongly. Filter through a porous glass filter, mix 20 ml. of the filtrate with 6.0 ml. of water, add 1 drop of 8.5% *w/v* sodium hydroxide solution and shake vigorously. No turbidity is produced immediately or within one minute. (b) The rotation of a solution of 0.746 g. in 1 ml. of 9.8% *w/v* sulphuric acid and 1 ml. of 7.3% *w/v* hydrochloric acid with sufficient water to make 20 ml., at 20° and in a 200 mm. tube should be between -17.8° and -18° .

Other cinchona alkaloids are excluded from Chininum dihydrochloricum, *P. Helv. V*, and from Chininum hydrochloricum, *P. Helv. V*, by dissolving 0.6 g. of the acid salt in 7.5 ml. of boiling water and neutralising with 1% ammonia to methyl red, or 0.5 g. of the hydrochloride in 15 ml. of boiling water, then adding 6 ml. of potassium chromate solution, cooling, shaking well and filtering, when on adding 2 drops of dilute sodium hydroxide solution to the filtrate no change occurs (quinidine); after warming for 1 hour on a water-bath and then standing for 24 hours the solution remains clear (cinchonidine). The angular rotation of 0.794 g. of the dried acid salt in 2 ml. of dilute sulphuric acid and water to 20 ml. in a 200 mm. tube or of 0.721 g. of the hydrochloride is -17.8° to -18.0° (other cinchona alkaloids).

The monohydrate is the *Quininæ Hydrobromidum* of the *N.F. VII*; it should lose not more than 5% at 100°. In the *Fr. Cx.* 1937 the test for other alkaloids in quinine sulphate is carried out as follows:—Dissolve, by refluxing 1 g. in 34 ml. of water, cool rapidly to 15°, maintain at this temperature, with frequent shaking, for 30 minutes and filter; 5 ml. with 5 ml. of dilute ammonia remains clear for 24 hours. 5 ml. of the filtrate evaporated and dried at 100°, does not weigh more than 0.008 g. Also 0.5 g. dried at 100°, dissolved in 20 ml. water with 2.5 ml. N/10 sulphuric acid has a α_D of -240° . Quinine sulphate is the dihydrate and should lose 4 to 5.1% at 110°.

Tabellæ Quininæ Sulphatis (U.S.P. XII). Contain 94 to 106% of the labelled amount of $(C_{20}H_{24}N_2O_3)_2 \cdot H_2SO_4 \cdot 2H_2O$, including all tolerances. Assayed by the method described for quinidine sulphate tablets.

Quininæ et Æthylis Carbonas (B.P. Add. I). M.p. not below 90°. Loss over sulphuric acid for 24 hours, not more than 2%. Ash, not more than 0.04%. Practically all commercial samples have a melting-point of about 89° to 91° after drying over sulphuric acid, but it is difficult to obtain consistent results unless a standard method of procedure is adopted. *Quininæ Æthylcarbonas*, *U.S.P. XII*, has a m.p. of 89° to 91°.

Quininæ Phosphas (N.F. VII) has 5 molecules of water of crystallisation and yields 74 to 78% of anhydrous quinine.

Liquor Quininæ Ammoniatas (B.P.). Contains 1.9 to 2.1% w/v of Quinine Sulphate and 0.9 to 1.05% w/v of NH_3 . Quinine is determined by extraction with chloroform and the ammonia is titrated directly with N/2 hydrochloric acid using methyl red indicator.

For a method for the extraction of quinine from viscera, see under *Morphina*, p. 307.

Tanret's Reagent. Potassium iodide 3.32 g., mercuric chloride 1.35 g., acetic acid 20 ml., diluted with distilled water to 60 ml. Precipitates alkaloids and albumin. Better than Mayer's for quinine test in urine, providing urine is albumin-free.

Determination by Absorption Spectrophotometry. Quinine salts have a strong absorption band in the near ultra-violet and the transmission curve of a solution of quinine in dil. hydrochloric acid shows maximum absorption at ca. 340 m μ . Of the compounds used with quinine in medications, strychnine, acetanilide, acetylsalicylic acid, camphor, phenolphthalein, caffeine, most blue, green and red dyes, glycerin, alcohol and sugars have no absorption bands near 340 m μ and quinine may be determined directly in the presence of these. Solutions of ferric salts absorb strongly in this region, but the colourless complex of the ferric ion and phosphate ion has no absorption band in this region.—J. Carol, *Analyst*, 1942, 299.

Mepacrinæ Hydrochloridum (B.P. Add. VI).

$C_{23}H_{30}ON_3Cl \cdot 2HCl \cdot 2H_2O = 508.7$. Loses from 6 to 8% at 130° and then contains not less than 99.0% of the pure substance. Determined by extraction with chloroform from a solution made alkaline with sodium hydroxide and drying at 100°. Limit of 2-chloro-7-methoxyacridone, 0.05%. *Quinacrinæ Hydrochloridum*, *U.S.P. XII*, assayed by precipitation with excess N/10 potassium dichromate from a solution containing sodium acetate and glacial acetic acid, filtration and determination of the excess N/10 potassium dichromate iodometrically in an aliquot of the filtrate, contains 77 to 80.2% of anhydrous base, corresponding

to not less than 98% of $C_{23}H_{30}ClN_3O \cdot 2HCl \cdot 2H_2O$. Loss on drying at 105° , 6 to 8%; pH of 1% solution, about 5.

Tabellæ Quinacrinæ Hydrochloridi (*U.S.P. XII*). Contain 95 to 110% of the labelled amount of $C_{23}H_{30}ClN_3O \cdot 2HCl \cdot 2H_2O$, including all tolerances. In the assay, a weighed quantity of powdered tablets is triturated twice with ether and the ether extracts discarded. Solution of ammonia is added to the residue which is then extracted completely with ether. To the combined ether extracts, glacial acetic acid is added and the ether removed. The residue is treated with water, sodium acetate and glacial acetic acid and the assay completed as described for quinacrine hydrochloride.

Mepacrinæ Methanosulphonas (*B.P. Add. VI*).

$C_{23}H_{30}ON_3Cl \cdot 2CH_3SO_3H \cdot H_2O = 591.9$. Contains not less than 99.0% of the pure substance, calculated with reference to the substance dried at 130° . The filtrate from shaking with 40 parts of anæsthetic ether shows no greater fluorescence than a solution of 0.25 mg. of chloromethoxyacridone in 100 ml. of anæsthetic ether. Loses from 2 to 4% at 130° .

Pamaquinum (*B.P. Add. IV and VI*). $C_{42}H_{45}O_7N_3 = 703.4$. The anhydrous substance yields 43 to 45% of 6-methoxy-8-(ω -diethylamino- α -methylbutyl)-aminoquinoline, by extraction with benzene from sodium hydroxide solution and drying at 100° for one hour in an atmosphere of nitrogen; and by precipitation from the alkaline solution with hydrochloric acid and subsequent drying at 105° , 53 to 57% of 2:2'-dihydroxy-1:1'-dinaphthylmethane-3:3'-dicarboxylic acid. A limit for 6-methoxy-8-aminoquinoline is included. Loss at 100° for 2 hours, not more than 4%. Residue on ignition with sulphuric acid, not more than 0.2%. Pamaquinæ Naphthoas, *U.S.P. XII*, yields not more than 1% ash and otherwise complies with the same standards for purity. Assayed for the acid by acidification of a solution with dilute hydrochloric acid and allowing the mixture to stand overnight. The precipitate is then collected on a tared filtering crucible, washed and dried at 100° . Pamaquin base is determined in the combined washings and filtrate by cooling to 15° , adding crushed ice, and slowly titrating M/10 sodium nitrite until the titrated solution, after being allowed to stand 1 minute, gives a blue colour with a smear of starch-iodide paste, used as an external indicator. 1 ml. M/10 sodium nitrite = 0.03154 g. of pamaquin base.

Biological Test for Antimalarial Remedies. Numerous substances have been introduced for the treatment of malaria such as mepacrine and pamaquin, and their value is determined in the first place by examining their effect in bird malaria.

The method of carrying out the biological test is as follows:—Canaries are infected, the heads of the infected birds are cut off, and the blood is filtered through glass wool into 1% citrate saline, so that the blood becomes diluted 5 or 10 times. This dilution is kept at 37° and injected into normal birds within 25 minutes. The injection is made into the pectoral muscles. If the dilution of blood is not kept at 37° the appearance of parasites is later in those birds which are last inoculated. The average time of the appearance of parasites in untreated birds varies from 4 to 8 days. (See G. A. H. Burtle, T. A. Henry and J. W. Trevan, *Biochem. J.*, 1934, 426.)

To test the efficacy of any unknown preparation, a group of birds is treated with some substance, such as quinine, used as standard, and a second group is treated with the preparation to be tested. The first dose is given about 4 hours after the canary is infected, and subsequent doses once daily

for the next five days; the doses are given orally by means of a thin piece of rubber tubing passed down the gullet. The birds are then observed in order to discover how many days elapse before the parasites appear in their blood; the average time for the appearance of parasites in a group of birds which received the same dose is then determined, and the average time for the unknown preparation is compared with the average time for the standard. Thus, a group of six birds which received a total dose of 30 mg. of quinine, reckoned per 20 g. bird weight, showed parasites after an average of 18.2 days, while a group receiving the same dose of dihydrocinchonidine showed parasites after an average of 9.3 days. Thus dihydrocinchonidine is less efficient than quinine in treating bird malaria.

CINCHOPHENUM

Cinchophenum (B.P.). $C_{16}H_{11}O_2N=249.1$. By titration in warm alcohol with N/1 sodium hydroxide using phenolphthalein indicator, the dried substance contains not less than 99% of $C_{16}H_{11}O_2N$. Loss in a vacuum desiccator over sulphuric acid, not more than 1%. Ash, not more than 0.2%. M.p., 214° to 217° . The *N.F. VII* requires Cinchophenum to contain 99.5% of the pure substance after drying at 100° ; loss at 100° , not more than 2%; ash, not more than 0.25%. Acidum phenylcinolin-carbonicum, *P.G. VI*, melts between 208° and 213° . Acidum phenylcinchoninicum, *P. Helv. V*, m.p. 208° to 210° .

Tentative methods for the determination of cinchophen in the presence of salicylates and of sodium bicarbonate are described in *Methods of Analysis* (A.O.A.C., 1940, 607). In the presence of salicylates, the cinchophen, extracted from the sample with sodium carbonate solution, is dissolved in warm acetic acid, treated with an excess of standard iodine and back-titrated with standard sodium thiosulphate, using starch indicator. When sodium bicarbonate is present, sodium hydroxide is added to the sample to dissolve the cinchophen, the solution is acidified with hydrochloric acid and extracted with chloroform. The residue from evaporation of the chloroformic extract is dissolved in alcohol, and the solution titrated with sodium hydroxide, using phenolphthalein as indicator.

Tabellæ Cinchopheni (*N.F. VII*). Contain 92.5 to 107.5% of the labelled amount of cinchophen including all tolerances. Assayed by preliminary extraction with chloroform, discarding the chloroform, then extracting the residue with neutral alcohol at 65° to 70° , filtering and titrating with N/10 sodium hydroxide using phenolphthalein indicator.

Tabellæ Neocinchopheni (*U.S.P. XII*). Contain 94 to 106% of the labelled amount of $C_{16}H_{11}O_2N$, including all tolerances. Assayed by refluxing twice a weighed quantity of powdered tablets with alcohol, passing the hot alcohol through a filter, finally washing the residue on the filter with small portions of alcohol, then refluxing an aliquot of the alcoholic solution with N/10 alcoholic potassium hydroxide for 1 hour, cooling and titrating the excess alkali with N/10 hydrochloric acid, using phenolphthalein indicator and subtracting from the alkali reading in this titration the figure obtained when a second aliquot of the alcoholic extract of the tablets is mixed with an excess of N/10 alcoholic potassium hydroxide and back titrated with N/10 hydrochloric acid, using phenolphthalein indicator.

CINNAMOMUM

Cinnamomum (B.P.). Ash, not more than 7%. Acid-insoluble ash, not more than 2%. Cinnamomum, *U.S.P. XII*,

from *Cinnamomum Loureirii* Nees, should yield not less than 2.5% *v/w* of volatile oil; foreign organic matter, not more than 2%.

Cortex Cinnamomi, *P.G. VI*, is required to contain not less than 1% of volatile oil. Cortex Cinnamomi ceylanici, *P. Helv. V*, should yield not less than 1.3% of cinnamic aldehyde when assayed by the following process:—Steam distil a mixture of 6 g. of powdered bark and 100 ml. of water, and treat the first 300 ml. of the distillate with a cold solution of 0.25 g. of semioxamazide in 15 ml. of water; shake well for 10 minutes, and allow to stand for at least 20 hours, agitating the mixture occasionally. Collect the precipitate on a tared Gooch filter dried at 150°, wash the precipitate with water, dry for 2 hours at 140° to 150° and weigh after allowing to cool over sulphuric acid. The weight of precipitate, multiplied by 10.14, gives the percentage of aldehyde in the bark. Cortex Cinnamomi chinensis, *P. Helv. V*, must give not less than 1.5% of cinnamic aldehyde.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined cinnamon as the dried bark of cultivated varieties of *Cinnamomum zeylanicum* Nees or of *C. cassia* (L.) Blume from which the outer layers may or may not have been removed, (*Ceylon Cinnamon*), as the dried, inner bark of cultivated varieties of *Cinnamomum zeylanicum* Nees, (*Saigon Cinnamon*), cassia as the dried bark of cultivated varieties of *Cinnamomum cassia* (L.) Blume and *Ground Cinnamon*, ground cassia, as the powder made from cinnamon. Contained not more than 5% total ash and not more than 2% ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1938.*

The figures for the area of fibres per gramme of powdered cinnamon and cassia bark are 92.5 and 13.1 respectively and hence can be used for the quantitative estimation of cassia in cinnamon or *vice versa*. In addition, the figure for cinnamon varies with the quality of bark and may also be used as a criterion of the quality of the sample.—A. H. Saber, *Quart. J. Pharm.*, 1940, 7.

Artificial cinnamon produced in Germany consists of a mixture of 96% cinnamic aldehyde and 4% eugenic acid which is incorporated in a powder carrier made from pulverised shells of hazelnuts or almonds coloured with a brownish-yellow material. The artificially coloured powder, after drying, is thoroughly mixed with the cinnamic aldehyde-eugenic acid mixture and 0.2% of Ceylon cinnamon oil added to give the fragrance of natural cinnamon.—per *Mfg. Chem.*, 1941, 164.

Oleum Cassiæ (B.P.C.). From *Cinnamomum Cassia* Blume. Assayed by the *B.P.* method for Oleum Cinnamomi should contain not less than 80% *w/w* of aldehydes as C_9H_8O . Sp. gr., 1.055 to 1.065. n_{D20}^{20} , 1.600 to 1.606. Soluble in 2 volumes of alcohol (80%, sp. gr. 0.8634 to 0.8640) and 3 volumes of alcohol (70%, sp. gr. 0.8896 to 0.8901). Oleum Cinnamomi Cassiæ, *P. Helv. V*, contains at least 80% of cinnamic aldehyde; assayed by treatment with water and warm semioxamazide solution and weighing the precipitate after drying at 140° to 150° for 2 hours; 1 g. = 0.6083 g. of cinnamic aldehyde.

Imported oil generally contains lead in excess of the *B.P.C.* limit; it is derived from the leaden vessels in which the oil is received.

Direct determination of total aldehydes in cassia oil. For a method which is stated to avoid the error caused in the ordinary process by the too great excess of the bisulphite reagent, see F. D. Dodge, *Amer. Perfum.*, 1929, 24, 11, per *Quart. J. Pharm.*, 1929, 328.

Seven classes of cassia oil, Saigon, Honan, China, Kwongsai, Korintji and Batavia and Ceylon Cinnamon bark oil, are examined for yield of oil from the bark and for their physical constants, aldehyde content, and acid value and ester value of the non-aldehyde portion. The Ceylon cinnamon bark oil is

characterised by its uniform yield of volatile oil and its lower aldehyde content.—J. F. Clavenger, *J. Ass. agric. Chem.*, 1941, 24, 461-464.

Petroleum Adulteration. Large quantities of imported oils contain this adulterant. If 25 or 50 ml. of the oil is steam distilled and the first 10% collected the oily portion of this distillate will separate into two layers the upper of which will be petroleum, which may be identified by tests.—W. H. Simmons, *Perfum. essent. Oil Rec.*, 1935, 408; C. T. Bennett, *ibid.*, 216.

Oleum Cinnamomi (B.P.). From *Cinnamomum zeylanicum* Nees. Assayed by the B.P. method by interaction with hydroxylamine hydrochloride solution and titration with N/2 potassium hydroxide in 60% alcohol. Cinnamic aldehyde content, 50 to 65% w/w. Sp. gr., 1.000 to 1.030. α_D , 0° to -2°. n_{D20}° , 1.565 to 1.586. Soluble in 3 volumes of 70% alcohol with only a faint opalescence. Oleum Cinnamomi, U.S.P. XII, obtained from cassia, *Cinnamomum Cassia* (Linné) Blume, contains not less than 80% v/v of cinnamic aldehyde; determined by measurement of the oil unabsorbed by saturated sodium sulphite solution, neutralising to phenolphthalein with sodium bisulphite solution, by heating in a water-bath and then heating for a further 15 minutes; sp. gr. at 25°, 1.045 to 1.063; α_D at 25°, +1° to -1°; n_{D20}° 1.6020 to 1.6135. Essence de Cannelle de Ceylan, Fr. Cx. 1937, contains 65 to 75% of cinnamic aldehyde.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined oil of cinnamon, oil of cassia, oil of cassia cinnamon, for food purposes, as the lead-free volatile oil from the leaves or bark of *Cinnamomum cassia* (L.) Blume; it was required to contain not less than 80% v/v of cinnamic aldehyde. Oil of Ceylon cinnamon, the lead-free volatile oil from the bark of the Ceylon cinnamon (*Cinnamomum zeylanicum* Nees), was required to contain not less than 65% w/w of cinnamic aldehyde and not more than 10% w/w of eugenol.—S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.

The aldehyde limits have been restricted in order to eliminate factitious oils containing artificial cinnamic aldehyde and redistilled cassia oil which, although often sold as B.P., lack the true cinnamon oil odour. English distilled oils possess the finest aroma and invariably contain a low percentage of cinnamic aldehyde. Some years ago imported oils frequently contained a large proportion of cinnamon leaf oil but they are no longer marketed.—C. T. Bennett, *Pharm. J.*, i/1933, 150.

Analytical characters which differ from the B.P. but which are more in conformity with true cinnamon oil are given by Gildermeister and Hoffman, *Die Ätherischen Öle*, as follows:—Sp. gr., 1.023 to 1.040; α_D , 0° to -1°, seldom more; n_{D20}° , 1.581 to 1.591; aldehydes, 65 to 75%; eugenol, 4 to 10%; soluble in 2 to 3 volumes of 70% alcohol. Oils containing less than 65% or more than 75% of cinnamic aldehyde are suspect.

Genuine oils frequently fail to dissolve 1 in 3 of 70% alcohol, but are usually soluble in 4 to 5 parts.—Finnemore.

For details of *C. zeylanicum* root, bark, and leaf oils, and *C. cassia* oil, see *Bull. imp. Inst., Lond.*, 1921, 19, 323, per *Quart. J. Pharm.*, 1922, 63.

Powdered cinnamon stored in paper bags lost 11 to 33% of essential oil; stored in glass it lost 0 to 8% during one year.—I. Horváth, per *Quart. J. Pharm.*, 1933, 607.

The physical and chemical constants of cinnamon leaf oil from Uganda, *Quart. J. Pharm.*, 1935, 122, and from the Seychelles, *Quart. J. Pharm.*, 1935, 256. The production of cinnamon bark and cinnamon leaf oils in the Seychelles are described.—Haines, *Perfum. essent. Oil Rec.*, 1936, 6 and 52.

COCAINA

Cocaina (B.P.). $C_{17}H_{21}O_4N = 303.2$. M.p., 97° to 98°. Ash, not more than 0.1%. Tests for absence of isoatropyl-cocaine,

and limit of cinnamyl-cocaine are included. The lower limit for the melting-point in the B.P. is too high, the majority of commercial samples having a melting-point of about 96° to 97° .

Constitutionally, cocaine is ecgonine with the hydrogen atoms in the carboxyl and hydroxyl groups replaced by a methyl and benzoyl group respectively.

Purification of Crude Cocaine. Cocaine, truxilline and cinnamyl-cocaine, being ecgonine derivatives, yield ecgonine, acids, and methyl alcohol on hydrolysis. This fact is of importance commercially as the amorphous residue remaining after extracting as much as possible of the crystalline cocaine can be converted into ecgonine, and this by treatment with benzoic anhydride and methyl alcohol can be converted synthetically into cocaine.

Although formerly care was taken in the extraction to preserve the cocaine, manufacturers now rely on the ecgonine content. After isolation of the crude "cocaine," it is treated so as to reintroduce the methyl and benzoyl groups.

β -Naphthalenesulphonic acid may be used for purifying crude cocaine. Crude cocaine, 10 g., is dissolved in hot water containing 5 g. of the acid and the solution filtered warm. On cooling, an oily resinous body deposits which becomes semi-crystalline. Ammonium carbonate is added, then solution of ammonia which produces a white precipitate. This is extracted with ether and the pure cocaine crystallises out from the ethereal solution. The acid used may be recovered by concentrating the mother liquors and precipitating with hydrochloric acid.

Another method is to dissolve crude cocaine in boiling water containing acetic acid. On cooling, precipitate with ammonium carbonate yielding a resinous yellow precipitate lighter than water. The solution is filtered and ammonia added. The cocaine is crystallised from ether.

The ecgonine contained in the resinous precipitate can be worked up. The residue is purified by crystallisation from alcohol and pure ecgonine precipitated by sodium carbonate. It is dissolved in methyl alcohol and the solution treated with anhydrous hydrochloric acid. Of the methylecgonine obtained, 20 g. is heated on a water-bath with benzoyl chloride, 20 g., until no more hydrochloric acid is evolved. The solution is added to cold water. Benzoic acid is precipitated. This is filtered out and the filtrate concentrated. The synthetic cocaine (termed coca-ethylene in the German Patent 47,713) is then precipitated from the filtrate by means of ammonia.—De Rosemont, *J. suisse Pharm.*, Apl. 29, 1920, per *Chem. & Drug.*, ii/1920, 934.

A tentative method for the determination of cocaine is described in *Methods of Analysis* (A.O.A.C., 1940). A portion of the mixed sample containing approximately 0.2 g. of alkaloid dissolved in 20 ml. of water with 2 drops of 10% hydrochloric acid is made alkaline with fresh saturated sodium bicarbonate solution and shaken out with petroleum ether. The petroleum ether is shaken with excess of N/50 sulphuric acid and the aqueous layer and washings from the petroleum ether back titrated with N/50 alkali using methyl red indicator. To the titration liquid 10 ml. of 2.5N sodium hydroxide is added and evaporated to about 10 ml. After cooling, the liquid acidified with 10% hydrochloric acid is extracted with chloroform, the chloroform evaporated spontaneously and the benzoic acid, after drying in a vacuum desiccator for 2 hours, is weighed.

Tests for Cocaine

PERMANGANATE TEST. When a drop of a solution of cocaine is placed on a dried film formed by a solution of potassium permanganate on a micro slide and examined under the microscope, oily drops are seen. If, however, the cocaine is dissolved in a saturated solution of alum, violet crystals of cocaine permanganate will quickly be observed. Alypin, tropacocaine and scopalamine produce crystals from aqueous solutions. Beta-eucaine, Stovaine, Novocain and holocain form no crystals with permanganate. Saporetti's bromine test distinguishes.

REICHARD'S TEST consists in adding a concentrated solution of sodium nitroprusside, drop by drop, to a cocaine salt solution containing at least 0.004 g. cocaine per millilitre. A precipitate of reddish crystals is formed which dissolves on warming and reappears after the liquid is cooled.

PISANI'S TEST. A wine-red colour is obtained by heating together cocaine or cocaine hydrochloride with a few drops of concentrated sulphuric acid containing 2% formamide. The colour soon disappears, giving place to a brownish-grey precipitate. The test is stated to detect 0.001 g. cocaine.—Autenreith, *Detection of Poisons and Powerful Drugs*.

With chromic acid and cobalt nitrate, Alypin behaves similarly to cocaine and eucaine and precipitates with usual alkaloidal reagents, caustic and carbonated fixed alkalis, and ammonia.

The four alkaloids, cocaine, truxilline, $C_{15}H_{21}NO_4$ (also called cocamine or isotropyl-cocaine), cinnamyl-cocaine and tropacocaine, $C_8H_{11}NO, C_6H_5CO$, are known to exist in coca leaves.

VITALI'S REACTION. Cocaine gives a reaction similar to atropine if the alkaloidal residue, after mixing with alcoholic solution of potassium hydroxide, is heated on the water-bath, but gives no reaction in the cold—the reaction in this case, however, is found to be due to isotropyl-cocaine as impurity.—*Yearb. Pharm.*, 1922, 7. Further experiments to show that the colour is due to esters of the tropic acid series.—*Yearb. Pharm.*, 1923, 24.

Cocainæ Hydrochloridum (B.P.). $C_{17}H_{21}O_4N, HCl = 339.6$. M.p. not lower than 197° , when placed in the heating bath at 193° . Specific rotation in 2% w/v aqueous solution, -70° to -72° . Ash limit, 0.1%. The substance of the *U.S.P. XII* has a specific rotation, in 2% aqueous solution, of -71° to -73° ; loss on drying over sulphuric acid, not more than 1%. Tests for acidity, carbonisable substances, cinnamyl cocaine and isotropyl cocaine are included.

It should not only be in good crystals, but should, by the following modification of MacLagan's Test, yield a distinctly crystalline precipitate of pure cocaine within 3 minutes when 1 grain is dissolved in 2 oz. of distilled water, and 6 to 8 drops of dilute solution of ammonia, *B.P.*, are added and well stirred. If more than 4% of amorphous alkaloid (principally truxilline) be present, there will be only a cloudiness. The precipitate redissolves after 24 hours or more, the cocaine being converted into methyl alcohol and benzoyllecgonine. Truxilline is highly toxic. (*Fr. Cx.* 1937 and *P.G. VI* give this test in modified forms.)

Cocæ Folia. The leaves from Bolivia, Peru and Ceylon contain cocaine as their chief alkaloid, whilst the Java leaf contains chiefly cinnamyl-cocaine, but little or no cocaine, chemical treatment being necessary to convert the alkaloids into cocaine. The genus *Erythroxylon*, which yields cocaine alkaloids and is indigenous to 4 continents, comprises about 80 species of which only 4 or 5 have so far been completely examined as regards alkaloidal content. The commercial supply comes from at least three distinct species.—*Plant Alkaloids*, T. A. Henry.

League of Nations Assay. The Health Committee have published the Committee of Experts' method for the assay of raw cocaine and coca leaves.—*Bull. Hlth Org. L. o. N.*, 1938, 429.

Suggested modifications to the method of the Committee of the Health Organisation of the League of Nations (*Quart. J. Pharm.*, 1938, 765) consist of firstly powdering the leaves finely rather than coarsely and, secondly, extracting the alkaloids from the acid by using 5 g. of sodium bicarbonate or 5.5 ml. N/1 sodium carbonate and three 30 ml. portions of ether.—A. W. K. De Jong, *per Quart. J. Pharm.*, 1939, 116.

Liquid Extract of Coca. The *B.P.C.* assay requires modification. The extraction of the alkaloids from ammoniacal solution should be made with successive portions of ether until complete, and sufficient dilute acid should be used to extract the alkaloids completely. The final ethereal solution must be washed with a little water to remove any traces of ammonium salts and the final residue dehydrated with absolute alcohol and heated at 80° for 2 hours to remove volatile bases.—W. A. Markwell, *Pharm. J.*, i/1935, 416.

Assay of Preparations containing Cocaine or Coca Alkaloids. Cocaine is not precipitated by sodium bicarbonate from solutions of its salts but after the addition of bicarbonate it can be extracted by immiscible solvents. Other alkaloids and local anaesthetics are only extracted very slowly under these conditions and if the solvent used is light petroleum, few are extracted. In the few cases where traces of alkaloids other than cocaine are extracted, they may be destroyed by treatment with potassium permanganate which does not affect cocaine appreciably in acid solution. The extracted residue or the original sample is dissolved in N/10 sulphuric acid and a 3% solution of potassium

permanganate in N/2 sulphuric acid is added until the colour indicates an excess. The solution is decolorised with oxalic acid, made alkaline with sodium bicarbonate and extracted with light petroleum. If permanganate treatment has not been employed, the other bases may be obtained by liberation with ammonia and extracting with a solvent.

Coca preparations contain cocaine and other ecgonine derivatives of similar constitution to cocaine, and also physiologically inert bases, such as the hygrines. Only cocaine and the related alkaloids come within the Dangerous Drugs Acts. In order to determine only the cocaine alkaloids, the bases should be liberated by sodium bicarbonate and a mixture of equal parts of ether and light petroleum used for the extraction. By this procedure the hygrines are not extracted. In the B.P.C. assay for Ext. Cocæ Liq., cocaine alkaloids instead of total alkaloids can be determined by adding 1 g. of sodium bicarbonate to the mixed sulphuric acid extracts, and shaking out first with 20 ml. of a mixture of equal parts of ether and light petroleum, and then with two successive portions, each of 15 ml., of the same mixture. The combined extracts are filtered, the solvent evaporated and the residual cocaine alkaloids dissolved in excess of acid and back titrated.—J. R. Nicholls, *Analyst*, 1936, 155.

The total alkaloids in coca leaves vary from about 0.5 to 1.5%, the cocaine alkaloids usually amounting to about 70 to 80%. A standard of 0.35 to 0.45% of cocaine alkaloids, calculated as cocaine, has been suggested for the B.P.C. liquid extract.

Determination of Cocaine in presence of Procaine Hydrochloride. Dissolve in water, treat with slight excess of sodium nitrate in presence of dilute sulphuric acid for three minutes. Add 10% sodium hydroxide and 1% β -naphthol solution, and compare the colour with that obtained from a solution of pure procaine hydrochloride. The amount of cocaine present is found by difference.—S. N. Chakravarti and M. B. Ray, per *Chem. Abstr.*, 1938, 1866.

Tabellæ Cocainæ Hydrochloridi (N.F. VII). Contain 91 to 109% of the labelled amount of cocaine hydrochloride, including all tolerances. Assayed by dissolving in water, making alkaline with ammonia, extracting with ether, reducing the ethereal extracts to half their volume, extracting with N/20 sulphuric acid and titrating the excess acid with N/50 sodium hydroxide, using methyl red indicator.

COCAINE SUBSTITUTES

Amydricainæ Hydrochloridum (B.P.C.). $C_{16}H_{26}O_2N_2.HCl$ = 314.7. M.p., about 169°. Loss at 100°, not more than 2%. Ash, not more than 0.1%.

Amylocainæ Hydrochloridum (B.P.). $C_{14}H_{21}O_3N.HCl$ = 271.6. M.p., 177° to 179°. Ash, not more than 0.1%.

Benzaminæ Hydrochloridum (B.P.C.). $C_{15}H_{21}O_2N.HCl$ = 283.6. M.p., about 268°, with decomposition. Loss at 100°, not more than 1%. Ash, not more than 0.1%. Eucainæ Hydrochloridum, U.S.P. XII, after drying at 100°, contains not less than 99% of $C_{15}H_{21}O_2N.HCl$; determined by titration in alcohol with N/10 sodium hydroxide using phenolphthalein indicator.

Benzaminæ Lactas (B.P.C.). $C_{15}H_{21}O_2N.C_3H_6O_3$ = 337.2. M.p., 152° to 156°. Loss at 100°, not more than 1%. Ash, not more than 0.1%.

Benzocaina (B.P.). $C_9H_{11}O_2N$ = 165.1. M.p., 90° to 91°. Ash, not more than 0.1%. *Æthylis Aminobenzoas*, U.S.P. XII, melts between 88° and 90°.

Butacainæ Sulphas (U.S.P. XII). $(C_{18}H_{30}N_2O_3)_2.H_2SO_4$ = 710.9. M.p., 100° to 103°; ash, not more than 0.2%. Complies with a test for carbonisable substances. (Butacaine sulphate is described in Vol. I under the trade name, Butyn.)

Butylis Aminobenzoas (*U.S.P. XII*). $C_{11}H_{15}O_2N=193.2$. M.p., 57° to 59° . Ash, not more than 0.15%.

Orthocaina (*B.P.*). $C_8H_9O_3N=167.1$. M.p., 141° to 143° . Loses not more than 1% at 100° . Ash, not more than 0.1%.

Phenacainæ Hydrochloridum (*U.S.P. XII*). $C_{18}H_{22}O_2N_2 \cdot HCl, 2H_2O=352.7$. Ash, not more than 0.1%; loss at 105° , not more than 7%; the dried substance on extraction with chloroform from ammoniacal solution, yields 87.5 to 90.5% of the base dried at 105° . M.p. of substance dried at 105° , not below 190° .

Procainæ Hydrochloridum (*B.P.*). $C_{12}H_{20}O_2N_2 \cdot HCl=272.6$. M.p., 154° to 156° . Ash limit, 0.1%. The *U.S.P. XII* substance leaves a negligible ash from 0.5 g. Procainum, m.p. 60° to 62° , Procainum hydrochloricum, m.p. 153° to 154° , and Procainum nitricum, m.p. 100° to 102° , are official in the *P. Helv. V*. The *Fr. Cx.* 1937 requires Chlorhydrate de *p*-Aminobenzoyl-diéthylaminoéthanol to have a m.p. of 154° to 155° .

Official quantitative methods for the determination of mixtures of procaine with any *p*-aminobenzoic acid due to decomposition of procaine, and of undecomposed procaine, and a tentative method for the determination of procaine in the presence of chlorbutol, cocaine, codeine, heroin, lactose and morphine are described in *Methods of Analysis* (*A.O.A.C.*, 1940, 590).

Tabellæ Procainæ Hydrochloridi (*N.F. VII*). Contain 92.5 to 107.5% of the labelled amount of procaine hydrochloride, including all tolerances. Assayed by extracting an ammoniacal solution with chloroform, filtering the chloroform extracts, removing the chloroform, dissolving the residue in N/10 sulphuric acid and back titrating with N/50 sodium hydroxide, using methyl red indicator.

A method for the determination of procaine in hypodermic tablets and injections, depending upon a diazo reaction followed by coupling with 1-amino 8-naphthol 3:6 disulphonic acid, is described. Tables are given correlating the value of the red compound in the colour produced with the amount of procaine present.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 243.

Tetracainæ Hydrochloridum (*U.S.P. XII*). $C_{15}H_{24}N_2O_2 \cdot HCl=300.8$. Loses not more than 1% when dried over sulphuric acid for 18 hours and then contains 86.5 to 88.5% of $(C_{15}H_{24}N_2O_2)$. M.p., 147° to 150° .

COLCHICUM

Colchici Cormus (*B.P.*). Contains not more than 2% of other organic matter. The corm dried at 65° contains not less than 0.25% of colchicine. Assayed by the same process as the seed, but subtracting the amount of the final residue which is insoluble in cold water. Colchici Cormus, *N.F. VII*, should yield not less than 0.35% of colchicine, and not more than 0.5% of acid-insoluble ash. Indian colchicum corm has a lower and more variable alkaloidal content; it is therefore a poor substitute for the British drug and there are difficulties in preparing standardised galenicals from it.

Assay of colchicum by phosphotungstic acid.—E. C. Davies, *Pharm. J.*, i/1921, 505. Iodine may also be employed as precipitant.

Estimation by shaking out the alkaloid with chloroform and precipitating with phosphotungstic acid (Scheibler's reagent). Precautions necessary in estimating colchicine due to the presence of an amino-acid grouping.—J. Grier, *Pharm. J.*, ii/1923, 87.

For the methods upon which the *B.P.* processes were formulated see Self and Corfield, *Quart. J. Pharm.*, 1932, 347.

Colchici Semen (*B.P.*). Other organic matter, not more than 2%. Contains not less than 0.3% of colchicine. Ash limit, 3%. Assayed by continuous extraction with alcohol, filtering the cooled and settled liquid, and evaporating to dryness; the solution of the residue in 20% *w/v* sodium sulphate solution is cleaned with ether, cleared with talc and filtered; an aliquot part of the filtrate is again cleaned with ether, shaken with chloroform, N/1 sodium hydroxide added and the alkaloid completely extracted with chloroform; the chloroform is evaporated, two portions of alcohol added and evaporated, and the residue dried at 100° and weighed. Colchici Semen, *U.S.P. XII*, yields not less than 0.45% of colchicine, when extracted by a lead subacetate process, the weight of residue insoluble in N/20 sulphuric acid with chloroform being deducted from the weight of residue from chloroform extraction. Colchique, *Fr. Cx.* 1937, by digestion with water, treatment with lead subacetate, followed by sodium phosphate and addition of sodium chloride before extraction with chloroform, finally drying at 105°, contains not less than 0.40% of total alkaloids. Semen Colchici, *P. Helv. V*, contains not less than 0.5% of colchicine and the powder for administration is adjusted with lactose to contain 0.4% of colchicine.

Extractum Colchici Liquidum (*B.P.*). Assayed after evaporation, by the process for Colchici Semen, it contains 0.27 to 0.33% *w/v* of colchicine.

Extractum Colchici Siccum (*B.P.*). Contains 0.9 to 1.1% of colchicine, assayed by the process for Colchici Cormus.

Tinctura Colchici (*B.P.*). Assayed similarly, contains 0.027 to 0.033% *w/v* of colchicine. Tinctura Colchici Seminis, *U.S.P. XII*, contains 0.036 to 0.044% *w/v* of colchicine.

Colchicina (*B.P.C.*). Ash, not more than 0.1%. Tests for limit of chloroform compound and of colchicine are described. Colchicinum, *P.G. VI*, $C_{22}H_{25}O_6N, \frac{1}{2}CHCl_3$, contains 87% of colchicine. Colchicinum, *P. Helv. V*, is the crystalline alkaloid, $C_{22}H_{25}O_6N + 1\frac{1}{2}H_2O$, containing from 6 to 7% of water of crystallisation.

Tabellæ Colchicinae (*U.S.P. XII*). Contain 90 to 110% of the labelled amount of $C_{22}H_{25}NO_6$, including all tolerances. In the assay, a weighed quantity of powdered tablets is first macerated for 5 minutes with light petroleum. The light petroleum is decanted through a filter and discarded, and the residue is then extracted twice with hot alcohol by gentle refluxing for 10 minutes. Each alcohol solution is passed through the filter which is then washed with hot alcohol until the runnings are colourless. The alcoholic extracts are then evaporated to dryness and the residue is dissolved in chloroform. The chloroform solution is filtered into a tared flask and the filter washed with chloroform until the runnings are colourless. After removal of the chloroform the residue is evaporated twice with 2 ml. of alcohol and finally dried at 100°.

COLOCYNTHIS

Colocynthis (*B.P.*). Should contain not more than 5% of seeds, 2% of outer sclerenchymatous pericarp, and should yield not more than 8% of acid-insoluble ash, and not more than 3% of light petroleum extractive dried at 100°. The *N.F. VII* limit of petroleum ether extractive is 2% dried over sulphuric acid for about 18 hours, and of acid-insoluble ash, 4%.

COLOPHONIUM

Colophonium (*B.P.*). Acid value, 150 to 180. Ash, not more than 0.1%. Resina, *U.S.P. XII*, should have a sp. gr. at 25° of 1.07 to 1.09, an acid number not less than 150, and should leave not more than 0.1% of ash; about 1 g. is used in determining the acid value.

Guaiaci Resina (*B.P.C.*). Should leave not more than 10% of matter insoluble in alcohol and not more than 4% of ash; should comply with a test for absence of colophony. Guaiacum, *N.F. VII*, gives no reaction for rosin with copper acetate; alcohol-insoluble residue, dried at 110° for 30 minutes, not more than 15%; acid-insoluble ash, not more than 2%. Résine de Gaïac, *Fr. Cx.* 1937, has an acid value of 89 to 97 and α_D about -17° .

COPAIBA

Copaiba (*B.P.*). Residue, when heated on a water-bath, 50 to 65%. Sp. gr., 0.960 to 0.995. Acid value, calculated on the non-volatile residue, 120 to 160. Optical rotation of the distilled oil, -7° to -35° . Copaiba, *N.F. VII*, has sp. gr. 0.930 to 0.995 at 25° and an acid value of the original balsam of 28 to 95; the residue insoluble in absolute alcohol and dried at 80° should be not more than 5%; the volatile oil, obtained by steam distillation, should not boil below 250° and in a 10 decimetre tube should show an angular rotation of not less than -7° at 25°.

Oleum Copaibæ (*B.P.C.*). Sp. gr., 0.895 to 0.908. Optical rotation, -7° to -35° . Refractive index at 20°, 1.495 to 1.500.

Terebinthina Canadensis. The balsam obtained from *Abies balsamea* Mill (*Pinaceæ*), known as Canada balsam. It has a refractive index approximating that of microscopic glass, and "sets" in a non-crystalline transparent condition, hence is used as a mounting medium. In preparing for use it has to be gently heated in an open dish for a week or more until a small quantity removed becomes brittle when placed on a cold slab. Canada balsam 1 part by weight in xylol, in turpentine, in benzol, and in chloroform, each 1 by measure, are prepared for microscopic use. The first mentioned is chiefly employed and is frequently designated "Xylol-Balsam."

CORIANDRUM

Coriandrum (*B.P.*). Limits: for foreign organic matter, 2%; for ash, 7%; and for acid-insoluble ash, 1%. Coriandrum, *N.F. VII*, should contain not more than 5% of foreign organic

matter, not more than 1.5% of acid-insoluble ash, and not less than 0.25% *v/w* of volatile oil.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined coriander seed as the dried fruit of *Coriandrum sativum* L. Required to contain not more than 7% total ash, and not more than 1.5% of ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

Oleum Coriandri (B.P.). Sp. gr., 0.870 to 0.884. α_D , +8° to +15°. $n_{D_{20}^{\circ}}$, 1.462 to 1.472. Should be soluble in 3 volumes of alcohol (70%, sp. gr. 0.8896 to 0.8901). The *U.S.P. XII* requires the oil to comply with the same solubility test; sp. gr. at 25°, 0.863 to 0.875; α_D , +8° to +15° at 25°; $n_{D_{20}^{\circ}}$, 1.4620 to 1.4720.

CREOSOTUM

Creosotum (B.P.). Sp. gr., not less than 1.070. Distillation commences at about 200°, and not less than 95% *v/v* is collected between 200° and 230°. Creosotum, *N.F. VII*, has a sp. gr. of not less than 1.076 at 25°. Not less than 90% *v/v* should distil between 203° and 220°.

Genuine beechwood creosote yielded 39% of monophenols, 26.48% of guaiacol, and 32.14% of creosol, $C_6H_3 \cdot CH_2 \cdot OCH_3 \cdot OH$, and homologues; pinewood creosote about the same but 20.3% guaiacol and 37.5% of creosol and homologues—all boiling between 200° and 210°.

Creosote is usually optically inactive but may be slightly dextrorotatory.

Creosoti Carbonas (B.P.C.). Sp. gr., 1.150 to 1.180. Ash, not more than 0.1%. Free creosote is excluded by the absence of any green colour developing on addition of ferric chloride to the alcoholic solution. The *N.F. VII* specifies a sp. gr. at 25° of not below 1.145; 85% of the separated creosote should distil between 200° and 220°, which should not respond to the tests for hydrocarbons and coal-tar creosote for Creosotum, *N.F. VII*. Creosotum carbonicum, *P. Helv. V*, yields not less than 90% *v/w* of creosote, which distils (apart from 2.83% which may pass over between 190° and 200°) between 200° and 220°, when determined by the following process:—Dissolve 20 g. in 60 g. of alcoholic potash and evaporate on a water-bath to 26 g. to 28 g. Add, drop by drop, dilute hydrochloric acid until distinctly blue to Congo red paper, and rinse into a graduated cylinder with 40 ml. water. After separation, the volume should be not less than 18 ml. Add 50 ml. of ether, transfer to a separator, draw off the salt solution and dry the ether with a little fused calcium chloride and transfer to a distillation flask. The distillate should comply with tests specified for Creosotum, *P. Helv. V*.

Calcii Creosotas (N.F. VII). Dried over sulphuric acid, it leaves on ignition 40 to 50% of CaO .

Guaiacol (B.P.). The liquid form has a sp. gr. of 1.116 to 1.125, and the crystals a m.p. of about 28°. Not less than 95% should distil between 200° and 210°. Guaiacol, *N.F. VII*, should have a sp. gr. at 25° of not below 1.112 for the liquid and of about 1.132 for the melted solid; the solid boils between 204°

and 206° and not less than 85% of the liquid distils between 200° and 210°.

A tentative method for the determination of guaiacol, guaiacol carbonate or potassium guaiacolsulphonate is described in *Methods of Analysis* (A.O.A.C., 1940, 608).

Guaiacolis Carbonas (B.P.C.). $C_{15}H_{14}O_5 = 274.1$. M.p., 85° to 88°. Ash, not more than 0.1%. Should comply with a test for absence of free guaiacol. The *N.F. VII* substance should leave not more than 0.1% of ash.

Potassii Guaiacolsulphonas (B.P.C.). $C_7H_7O_5SK = 242.2$. Should give not less than 35.2% of sulphated ash, corresponding to not less than 98% of the pure substance. The composition is incorrectly given as $C_6H_5(OCH_3)(OH)SO_3K$ (1 : 2 : 3). Potassii Guaiacolsulfonates, *N.F. VII*, on drying over sulphuric acid for 24 hours loses not more than 2%, and contains 95% of $C_7H_7O_5SO_3K$; assayed by digestion and evaporation with nitric acid and precipitation as barium sulphate.

Guaiacolsulfonate de Potassium, *Fr. Cx.* 1937, loses not more than 3% at 100°, contains not more than 2.42% of alkali as K_2CO_3 , and the dried salt contains 99% of the pure substance. Kalium sulfoguaiacolicum, *P.G. VI*, contains not less than 96.9% of $C_6H_5(OH)(OCH_3)SO_3K$ (1 : 2 : 4 and 1 : 2 : 5). Kalium guaiacol sulfonicum, *P. Helv. V*, is described as a mixture of salts of 1-oxy-2-methoxybenzene-4-(and 5)-sulphonic acids and is required to give from 35 to 39% of sulphated ash.

The potassium salts of guaiacolsulphonic acid may be determined by titration with N/10 sodium hydroxide to Poirrier-blue, followed by titration with N/10 hydrochloric acid using alizarin-yellow R as indicator.—*Brit. chem. Abstr.* (B), 1933, 171.

CRESOL

Cresol (B.P.). Sp. gr., 1.035 to 1.050. Distillation range, not more than 2% *v/v* below 188° and not less than 80% *v/v* between 195° and 205°. Not less than 90% *v/v* of cresol, *U.S.P. XII*, should distil between 195° and 205°. Sp. gr., 1.030 to 1.038 at 25°. Cresolum crudum, *P.G. VI*, and Cresolum crudum, *P. Helv. V*, contain not less than 50% of *m*-cresol when determined by nitration and weighing the trinitro-*m*-cresols produced. 10 g. of cresol is heated in a litre flask on a well-boiling water-bath for 1 hour with 30 g. of sulphuric acid; after cooling, 90 ml. of nitric acid is added all at once and when reaction has ceased, after standing 15 minutes, the contents of the flask are added to 40 ml. of water in a basin and the flask rinsed with a further 40 ml. of water. After cooling and standing for 2 hours the crystals of trinitro-metacresol are broken up with a pestle, transferred to a dried filter and washed with 100 ml. of water in small portions, dried for 1 hour at 50° and then for 2 hours at 100° (*P.G. VI*) or 95° to 98° (*P. Helv. V*). 1 g. metacresol = 1.74 g. of nitro-compound.

The method in *P. Helv. V* for the determination of *m*-cresol is inaccurate, particularly with samples containing more than 90% of *m*-cresol, owing to irregular nitration. An improved and accurate method is described.—H. Muhlemann, *Pharm. Acta Helvet.*, 1940, 15, 141.

British Standard Specifications:—

B.S.S. No. 522—1933, includes specifications for: (1) Orthocresol (522A), crystals or masses having a crystallising-point of 30.3° to 31.0° and a boiling-point of about 191°; (2) Metacresol (522B), colourless to very pale straw-coloured liquid or solid of sp. gr. 1.037 to 1.040 and having a crystallising-point of not below 10.5° and a boiling-point of about 202°; (3) Paracresol (522C), crystals or masses having a crystallising-point not lower than 34° and a boiling-point of about 202°.

B.S.S. No. 517—1933, describes Cresylic Acid of high orthocresol content. It must contain not less than 45% of orthocresol; the sp. gr. is from 1.045 to 1.050 at 15.5°, and 90% distils between 192° and 200°. The proportion of orthocresol is determined by observing the crystallising-point of a mixture of the sample and pure cineole under carefully controlled conditions.

B.S.S. No. 521—1933, describes the variety of commercial cresol known as Cresylic Acid, (50/55% Metacresol), a liquid having a specific gravity of 1.035 to 1.040 at 15.5° and of which approximately 92% distils between 199° and 204°. The proportion of metacresol is determined by a nitration process and weighing the washed solid trinitrometacresol produced.

B.S.S. No. 524—1933, includes specifications for Refined Cresylic Acids. Refined Cresylic Acid, Grade A, is controlled for colour, water content, specific gravity (1.035 to 1.050), distillation (not more than 5% below 192° and at least 90% below 205°), neutral oils and pyridine bases, sulphuretted hydrogen, and freedom from acids and alkalis. Refined Cresylic Acid, Grade B, may contain twice as much water (1%), 10 times as much neutral oils and pyridine bases (1% of each), and at least 80% must distil below 205°.

Tests to distinguish Carbolic Acid, Cresols and other Phenols.

TEST I. Dissolve 1 drop (0.05 g.) of the phenol in 10 ml. of strong hydrochloric acid in a mortar and add 0.5 g. of a mixture of NaNO_2 (1 part), NaNO_3 (1 part) and exsiccated Na_2SO_4 (2 parts). Stir well and allow to stand for 2 to 5 minutes. Note colour and pour 1 ml. of the acid mixture into excess of 10% aqueous NH_4OH and note change of colour.

Carbolic Acid gives a rich crimson colour in 2 minutes. On pouring the mixture into NH_4OH a deep emerald green results. If at the crimson stage 1 or 2 drops of 38% formaldehyde solution are added and the mixture stirred, the colour changes to rich purple and if now poured into NH_4OH a deep blue colour occurs. *Ortho-Cresol*. A dichroic solution is given in the acid, green being predominant. If a drop or two of formaldehyde solution is then added the green changes to blue (purple by transmitted light). If now poured into NH_4OH , only olive-green results. *Meta-Cresol*, *Para-Cresol* and *Cresol* give no distinctive results and are thus easily distinguished from carbolic acid and ortho-cresol. The presence of *p*-cresol also inhibits the reaction with carbolic acid or *o*-cresol, and the test cannot be used for detection of either of these in cresol. *B.P. Beta-Naphthol* and *Alpha-Naphthol* give crimson-purple and violet-purple respectively after standing 3 to 5 minutes in the acid mixture. The colours are destroyed by ammonia solution. The acid solution withstands heat and subsequent dilution with retention of colour better than with other phenols. *Thymol*, after stirring and leaving for 5 minutes, gives a pronounced green, becoming yellow on pouring into ammonia solution.

TEST II. Dissolve 1 drop of the phenol in 5 ml. to 10 ml. of strong HCl with a minute crystal (size of pin's head) of NaNO_2 . Slowly heat the mixture nearly to boiling; cool or dilute and pour into excess of dilute NH_4OH solution. Note the colour changes.

Carbolic Acid, *ortho-cresol* and *meta-cresol*: On pouring the acid solution into NH_4OH and warming, a deep blue colour results. *Para-cresol* gives no colour. In aqueous solution, acidified with acetic acid, together with a little NaNO_2 , and a few drops 1 to 2% CuSO_4 solution, a rich wine-red solution is given, turning to pink on dilution with water. *Guaiacol* gives a green with NH_4OH . *Resorcinol* gives successively brown, red, purple, violet and blue; on diluting with water, green, and on pouring the acid mixture into ammonia solution, a dichroic solution with brilliant red fluorescence, wine-purple to transmitted light. *Orcinol*, *phloroglucinol* and the *catechins* give rather poor reds or purples both before and after treatment with ammonia, *catechol* gives a distinct bluish-green in the acid mixture, and *pyrogallol* a purplish colour if heated with a nitrate in the acid mixture.—A. H. Ware, *Analyst*, 1927, 335.

The determination of meta- and ortho-cresols in mixtures of cresols can be made by formation of the aldehyde resins; the amount of ortho-compound can be found by the cineole freezing-point method and, by subtraction, the proportion of meta-cresol can be ascertained.—C. E. Sage and H. R. Fleck, *Analyst*, 1932, 567.

Liquor Cresolis Saponatus (B.P. Add. I). Should contain 47 to 53% *v/v* of cresol. Assayed by acidifying, extracting with ether, evaporating the ether, and steam distilling the residual liquid at 170°; the distillate is saturated with salt, extracted with ether, warmed to 170° and the residue weighed, the cresol distilled and the weight of water, etc., and non-volatile residue subtracted; the distilled cresol should have the sp. gr. and b.p. of cresol. Miscible in all proportions, up to 10% *v/v*, with water. **Liquor Cresolis Saponatus, U.S.P. XII**, is assayed by distillation with kerosene and extraction of the distillate with sodium hydroxide, when the proportion of cresol, measured by the increase in volume of the sodium hydroxide solution used, should be from 46 to 52% *v/v*; the cresol separated from this solution should comply with the distillation standard for cresol. **Liquor Cresoli saponatus, P.G. VI**, contains about 50% of crude cresol and 25% of fatty acids from linseed oil.

Assay of Cresols in Lysol. The following method is more suitable and accurate than that of the B.P. when only normal quantities of lysol are available. It can be used for less concentrated preparations of cresols and the higher homologues of phenol and for other coal tar disinfectants in which the phenols are dissolved in, or emulsified with, solutions of soaps or resins.

Weigh 25 to 100 g. of the liquid, according to the amount available and the phenolic content of the preparation, into a conical flask and shake with 100 ml. of water; add 15 to 50 g. of solid barium hydroxide and heat for one hour under a reflux condenser by immersing the flask in boiling water, shaking well at frequent intervals. After cooling, pour off the aqueous liquid and filter, washing the residue, and finally the filter, with hot barium hydroxide solution. Acidify the filtrate in a separating funnel with hydrochloric acid, saturate the mixture with calcium chloride and extract the liberated phenols with successive small portions of ether. Transfer the ethereal solutions to a small flask, evaporate off the ether, dry the phenolic residue to constant weight by heating on a water-bath and finally over sulphuric acid. The weight obtained gives the quantity of crude phenols in the weight taken, and the percentage by volume may be calculated from the specific gravity of the crude phenols obtained and that of the original liquid. The nature of the phenols recovered may be ascertained by submitting the residue to fractional distillation and weighing separately portions of the distillate collected within the boiling-ranges of phenol, cresols and the higher homologues.

The following are references to other methods:—

100 g. of lysol treated with excess 2% sulphuric acid, and the fatty acids and cresols extracted with 50 and 20 ml. of ether. The ethereal layer is dried over sodium sulphate and distilled, and the phenols collected between 180° and 230°.—A. H. Dodd, *J. Soc. chem. Ind., Lond.*, 1924, 931.

Cresols in lysols approximately estimated by steam distillation of 60 g. to 70 g. after acidifying with 30 ml. to 35 ml. of dilute sulphuric acid. The weight of cresol in the sample is obtained by multiplying the volume of cresols in the distillate by 1.04 and adding 1/50 of the volume of the aqueous layer. Method gives trustworthy results.—C. J. Jordan and F. Southerden, *Analyst*, 1921, 375.

Data given of a large number of examinations of castor oil and linseed oil lysols.—*Pharm. J.*, i/1921, 479.

Accurate results by distillation can only be assured when the soap is known to be free from volatile fatty acids. It is best to dissolve the sample in hot water in a separator, add a piece of stick caustic soda and shake until dissolved. Add excess of brine and separate. Redissolve in hot water, add caustic soda and again salt out; repeat again. Acidify the united alkaline liquors and extract

with benzene. Extract this solution with a small quantity of caustic soda, acidify and read off in the usual way.—G. F. W. Martin, *Yearb. Pharm.*, 1922, 142.

Lysols vary appreciably in characters and properties but very little adjustment will be necessary to make them comply with the official strength. The assay process is unnecessarily complicated and there is confusion between crude cresol and separated cresol. A large proportion of the higher phenols (non-volatile residue) is lost and it is useless to examine the separated cresol to see that it comes within the B.P. boiling-range.—*Pharm. J.*, ii/1932, 107.

The lysol supplied by the large manufacturers would comply with a requirement of miscibility with water up to 10%, or even 20%, of lysol, but does not, in the majority of cases, comply with the requirement of miscibility in all proportions. The statement of miscibility with ether does not hold for commercial samples.—G. R. Page, *Quart. J. Pharm.*, 1934, 369.

Chlorocresol (B.P. Add. III). $C_7H_7OCl = 142.58$. M.p., 64° to 66° . Residue on volatilisation on a water-bath, not more than 0.1%.

Chloroxilenol (B.P. Add. VI). $C_8H_9OCl = 156.5$. M.p., 114° to 115.5° . Ash, not more than 0.1%.

The Bactericidal and Fungicidal Action of Homologous Chlorophenols. Tables are given showing the germicidal activity of chlorophenol derivatives on *E. paratyphosus*, *B. paratyphosus*, pathogenic cocci, and acid-fast bacteria, and the fungicidal action on various fungi.

All the tests were carried out at 37° and in all cases 0.5 ml. of culture was added to 5 ml. of the various dilutions of the antiseptic substances. The method of culturing and preparing the organisms for the tests followed closely that described by Ruehle and Brewer (U.S. Dept. of Agriculture, Circular No. 198, Dec. 1931) in the case of *Eberthella typhi*, and transfers from the medication tubes into fresh media were made after exposures of 5, 10, and 15 minutes respectively and the readings taken after 48 hours' incubation. The "phenol coefficients" were calculated in all cases from the results of the ten-minute exposures to compounds under discussion on the one hand and to phenol on the other. A phenol control test always accompanied the tests with these compounds, carried out on any given day. Most of the derivatives were found to have a very low toxicity to mice, the minimum lethal dose (subcutaneously) varying from 0.6 to over 10 mg. per gramme body weight.—E. Klarmann, V. A. Shternov and L. W. Gates, *J. Lab. clin. Med.*, 1934, 19, 835, and 1934, 20, 40.

THE BACTERICIDAL ACTION OF ORTHOALKYL DERIVATIVES OF *p*-CHLOROPHENOL UPON ORGANISMS OF THE TYPHOID COLON GROUP

Minimum Concentrations Effective in 10 Min. (I) and Phenol Coefficient (II)

The effect of change of concentration on the relative activity of phenol and *parachlorometacresol*. By determination of the concentration exponent for phenol and *parachlorometacresol* by methods involving counting and calculated from the times for 50% death of *B. coli* (Type I), it was found that the latter bactericide increases in activity much more rapidly than phenol when concentrations are increased by the same amount. The reverse is true on decrease of concentration.—E. R. Withell, *Quart. J. Pharm.*, 1942, 313.

Determination of *p*-Chloro-*m*-xylene in Antiseptic Solutions.

20 ml. of solution is made alkaline with 2 ml. of 50% sodium hydroxide, the alcohol distilled off and the oils extracted by shaking twice with light petroleum. The light petroleum extract is washed twice with water, and the combined aqueous liquids are treated with 20% calcium chloride solution and filtered to remove soap. The filtrate and washings are acidified with hydrochloric acid and extracted with ether. The soap contains some adsorbed *p*-chloro-*m*-xylene which may be removed by three extractions with boiling alcohol, diluting, filtering, evaporating off the alcohol under reduced pressure, acidifying and extracting with ether. The mixed ethereal liquids are evaporated, the residue dissolved in the minimum quantity of alkali and the phenol compound precipitated by a current of carbon dioxide and extracted with ether. The ethereal solution is evaporated and the residue dried and weighed. The *p*-chloro-*m*-xylene obtained usually melts at about 110°; its identity can be confirmed after recrystallisation from benzene. If the solution contains a high proportion of essential oils, the phenolic residue may contain some oil which may be removed by treatment with light petroleum and alkali.—R. P. Merritt and T. F. West, *Analyst*, 1938, 257.

The following method has yielded satisfactory results for solutions containing a variety of soaps and essential oils. *Method.*—20 ml. of the antiseptic solution are pipetted into a separator and acidified with 6N sulphuric acid. The oily layer is extracted three times with ether (25 ml.), the combined ethereal extracts are washed three times with water (10 ml.) and the water washed with 15 ml. ether. The ethereal solutions are combined and dried over sodium sulphate and, after removal of the solvent, the residue is boiled for 45 minutes on a hot plate

under reflux with 20 ml. of a 4% solution of naphthalene- β -sulphonic acid in methyl alcohol. The solution is transferred to a separator with twice its volume of N sodium hydroxide solution and 20 ml. of petroleum spirit, and the mixture shaken vigorously. The petroleum spirit is extracted three times with N sodium hydroxide (10 ml.), a little alcohol being used if necessary to break the emulsions formed. The combined alkaline extracts are acidified with 6N sulphuric acid extracted three times with 25 ml. of ether, the ethereal extract is washed with water in the usual way and dried over sodium sulphate, the solvent is removed, the residue dried in a vacuum desiccator and weighed. In some instances the result at this stage is high and accordingly, as a general method, it is preferable to purify the crude phenol by dissolving in the smallest quantity of sodium hydroxide solution, diluting with water to 60 ml., and precipitating with carbon dioxide. The suspended phenol is then extracted with ether, separated, dried in the usual manner and weighed. This process may not be successful if essential oils containing phenols are included in antiseptics, although this appears unlikely in view of the oils available.—D. McNicoll, R. P. Merritt, and T. F. West, *Analyst*, 1939, 261.

Pentachlorophenol

Pentachlorophenol is a weak acid, soluble in alcohol. It is stable and melts at 190-2°. The sodium salt is soluble in water. It is used in the field of industrial preservation being a very efficient fungicide against widely differing types of organisms. The sodium salt is equally toxic.—T. S. Carewell and H. K. Nason, *Industr. Engng Chem.*, 1938, 30, 622.

CROCUS

Crocus (B.P.C.). Should lose not more than 12.5% of moisture and then yield not less than 60% of alcohol (60%) extractive; styles and anthers, not more than 8%, and foreign organic matter, not more than 2%; ash, not more than 7.5%; light petroleum extractive, not more than 1%. The water extract of 0.02 g. in 100 ml. yields a colour similar to and not less intense than 0.1% *w/v* potassium dichromate solution. The *N.F. VII* allows not more than 10% of yellow styles, not more than 2% of foreign organic matter, not more than 7.5% of total ash, and not more than 1% of acid-insoluble ash; a similar test for intensity of colour is included.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined saffron as the dried stigma of *Crocus sativus* L.; required to contain not more than 10% of yellow styles and other foreign matter, not more than 14% of volatile matter when dried at 100°, not more than 7.5% of total ash, and not more than 1% of ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5*, Nov. 1936.

Adulteration of saffron with carthamus flowers and calendula can be detected by the orange-red or clear-blue fluorescence of the material when exposed to ultra-violet light.—A. Castiglione, *Ann. Falsif.*, 1933, 26, 41.

CUPRUM

Cupri Sulphas (B.P.). $\text{CuSO}_4 \cdot 5\text{H}_2\text{O} = 249.7$. Estimated by interaction of the cupric salt with potassium iodide in solution containing 10% of acetic acid, the liberated iodine being titrated with standard thiosulphate solution, using starch mucilage as indicator. Should contain from 98.5% to the equivalent of 101% of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. No standard or method of assay was included in the *B.P. '14*. Cupri Sulphas, *U.S.P. XII*, contains from 63 to 66.8% of anhydrous compound, equivalent to not less than 98.5% of the crystallised substance.

Detection and Determination of Copper. Copper can be detected and determined by using sodium diethylthiocarbamate, $N(C_2H_5)_2CS_2Na$. The reagent is used as a 0.1% solution in water. On adding the reagent to 10 times its volume of test solution, previously made alkaline with ammonia, a golden-brown turbidity is produced in the presence of Cu. The determination is carried out by adding 10 ml. of reagent to the test solution containing 0.01 to 0.1 mg. of copper and made alkaline with ammonia. The resulting solution is diluted to 100 ml. and the colour of the liquid is compared with that of the liquid obtained by similarly treating solutions containing known amounts of copper. If preferred the coloured compound may be extracted from the aqueous solution by shaking with successive portions of carbon tetrachloride and the colour of the mixed extracts compared with that of standards treated similarly. Iron, if present, must be oxidised to the ferric condition, 2 g. of citric acid is then added and the liquid made more alkaline than pH 9 with ammonia. The copper is then determined as above, the coloured compound being extracted with carbon tetrachloride.

For a modified method in which acacia is used to stabilise the coloured compound, see *Analyst*, 1937, 657.

The coloured compound should be extracted with carbon tetrachloride before comparing the colours. The precipitation of ferric hydroxide causes a serious loss of copper and the diethylthiocarbamate reagent is too sensitive for medicinal substances.—N. Evers and L. A. Haddock, *Pharm. J.*, 1/1934, 452.

Small amounts of copper may be detected and determined by using benzoin oxime (*syn.* Cupron), $C_6H_5 \cdot CHOH \cdot C : NOH \cdot C_6H_5$. The reagent is used as a 1% solution in alcohol. (20 ml. of the solution to be tested is made slightly alkaline with ammonia and 1 ml. of the reagent added.) In the presence of copper a green precipitate is produced either at once or after some hours, according to the proportion present. In the absence of tartrate ions, precipitates are also given by Co, Ni, Pb, Fe and Al. For the determination of copper, the test solution, containing not more than 0.05 g. of copper, is treated with excess of solution of ammonia, raised to the boiling-point, and then treated with a slight excess (about 5 ml.) of a 4% alcoholic solution of the reagent. The precipitate is washed free from soluble salts with hot 1% ammonia solution, and then with hot alcohol to remove excess of the reagent. The precipitate is dried to constant weight at 110°. Each gramme of residue is equivalent to 0.2202 g. of Cu. In the presence of any interfering element, a solution of sodium potassium tartrate must be added to the test solution.

Minute amounts of Cu are found in chemicals and galenicals. In view of the value of such traces in hæmoglobin formation it is unlikely that they would be harmful.—N. Evers and L. Haddock, *Quart. J. Pharm.*, 1932, 458.

Copper in various chemicals ranged from 0.4 parts per million in hydrochloric acid to 68 in ferric glycerophosphate, and in galenicals from 4 in ammoniated tincture of valerian to 580 in *B.P.* 1914 extract of ergot.—N. Evers and L. A. Haddock, *Quart. J. Pharm.*, 1932, 458.

Detection and Determination of Copper and Nickel. Copper and nickel may be detected and determined by using salicylaldoxime, $C_6H_5 \cdot OH \cdot CH : NOH$. The reagent is used as a solution obtained by dissolving 1 g. in 5 ml. of alcohol and diluting to 100 ml. with water. The test solution is acidified with acetic acid and one-twentieth of its volume of the reagent solution is added. In the presence of copper an immediate precipitate is produced. **Determination of copper.**—The test solution, containing not more than 0.1 g. of copper, is treated with sodium hydroxide solution until a precipitate appears, and is then acidified with acetic acid. 50 ml. of the reagent solution is added and the liquid is stirred to coagulate the precipitate, and filtered. The precipitate is washed with cold water and dried to constant weight at 100° to 105°. Each gramme of precipitate is equivalent to 0.1894 g. of Cu. **Detection and determination of nickel.**—The test solution is adjusted to pH 7 to 8 and the reagent added. A green flocculent precipitate is produced in the presence of nickel. If traces only of nickel are present the solution becomes opalescent. The precipitate is stirred to effect coagulation, then filtered, washed, and dried at 100°. Each gramme of precipitate is equivalent to 0.1774 g. of Ni. Nickel and copper may be separately determined in mixtures by precipitating the copper first as described above in acid solution and then adjusting the filtrate and washings to pH 7 to 8 by means of ammonia, when the nickel complex is precipitated.

5-bromoanthranilic acid was shown to be superior to the unsubstituted acid

as an analytical reagent for a number of bivalent metals. *Reagent solution*.—5 g. of 5-bromoanthranilic acid were neutralised with sodium hydroxide and the solution diluted to 500 ml. The neutral solution gave no precipitates with calcium, barium, strontium and magnesium. *Determination of copper*.—A copper sulphate solution was diluted to 100 ml., a few drops of 5N acetic acid added, and the solution heated. 50 ml. of reagent were added per 0.05 g. of metal and gentle heating was continued for 30 minutes. Copper bromo-anthranilate was filtered off on a No. 4 sintered glass crucible, washed with hot water and dried at 105° to 110° for one hour. Factor for copper = 0.1288. In the presence of ammonium acetate and Rochelle salt, it was found necessary to use a threefold excess of reagent. *Determination of cobalt*.—The procedure was the same as for copper. Factor for cobalt = 0.1206. *Determination of nickel*.—Nickel bromoanthranilate was sparingly soluble in hot water, but satisfactory results were obtained by washing with a solution containing 0.1% of 5-bromoanthranilic acid. The precipitate was finally washed with a little cold water. Factor for nickel = 0.1200.—R. J. Sherman, *J. Soc. chem. Ind., Lond.*, 1942, 164.

Detection and Determination of Nickel. Nickel may be detected and determined by means of dimethylglyoxime (*syn.* diacetyldioxime), $\text{CH}_3\text{C}:(\text{NOH})\text{C}:(\text{NOH})\text{CH}_3$. The reagent is used as a 1% solution in alcohol. A few drops of the reagent are added to the boiling acidified test solution, and the mixture is then rendered alkaline with solution of ammonia. In the presence of nickel, red needles are produced. In the presence of a large excess of cobalt (for example, in testing for nickel in cobalt compounds), 2 g. of the cobalt compound is dissolved in 20 ml. of water, 40 ml. of 10% potassium cyanide solution is added, followed by 10 ml. of N/1 sodium hydroxide and 10 ml. of 20 vol. hydrogen peroxide. The mixture is heated in a water-bath for 10 minutes, 20 ml. of 10% ammonium chloride solution added and then 2 ml. of the reagent. The solution is then evaporated to dryness on a water-bath. In the presence of nickel red flocks separate during evaporation, or if the proportion is extremely small the residue, which is otherwise yellowish, will be tinged with pink. For the determination of nickel, the test solution should contain not more than 0.1 g. of Ni in 200 ml. After precipitation as above, the crystals are filtered off after 1 hour, washed with hot water and dried at 115° for 45 minutes. Each gramme of residue, $(\text{C}_4\text{H}_7\text{O}_2\text{N}_2)_2\text{Ni}$, is equivalent to 0.2032 g. of Ni. Nickel may also be determined colorimetrically. In the absence of cobalt and copper a slight excess of bromine water is added, followed by ammonia solution until the bromine colour is removed. A few drops of the reagent are then added. The intensity of the red colour produced is compared with that obtained with known amounts of nickel.

Insecticides. The specification of the Association of British Insecticide Manufacturers (Bulletin No. 82: Ministry of Agriculture and Fisheries) requires:

COPPER SULPHATE to contain not less than 98% crystallised copper sulphate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$);

BORDEAUX POWDER to contain no water-soluble copper, and the equivalent amount of copper to be declared;

CHESHUNT COMPOUND to consist of 2 parts of copper sulphate and 11 of ammonium carbonate by weight, and to contain not less than the equivalent of 3.8% Cu;

BURGUNDY POWDER to contain not more than 2% alkalinity expressed as Na_2CO_3 and no water-soluble copper, the whole of the powder to pass through a 30-mesh B.S. sieve.

Organic Copper Compounds.

Cupri Alloxanas. $(\text{N}_2\text{C}_4\text{O}_4\text{H})_2\text{Cu}$. A bluish-green flocculent powder slightly soluble in water. The relative insolubility is a disadvantage from the therapeutic standpoint.

Cupri Glycinas. $(\text{NH}_2\text{CH}_2\text{COO})_2\text{Cu}$. A blue flocculent silky powder soluble about 1 in 200 of water at 15°, but more than twice as soluble at 40°. 0.06 g. per kilo in 0.5% solution intravenously killed a rabbit in 8 minutes, whilst a control of Salvarsan in proportion 0.1 g. per kilo was tolerated, hence the substance has a toxic dose of about 2 g. for an average man.

Cupri Hippuras. $(\text{C}_6\text{H}_5\text{CO}\cdot\text{NHCH}_2\text{COO})_2\text{Cu}$. A bluish-green crystalline powder. Almost insoluble in water, but soluble about 1 in 200 of a mixture of glycerin and water equal parts. It is more soluble in pure glycerin.

DERRIS

Derris (*B.P.C. Supp. V*). By continuous extraction with carbon tetrachloride, concentrating, and standing at 0° (seeding if necessary), filtering and air-drying not above 40°, crystals of the carbon tetrachloride compound equivalent to not less than 2% of rotenone are obtained; (factor 0.719). Ash, not more than 6%; acid-insoluble ash, not more than 2%. Derris *Præparata*, *B.P.C. Supp. V.*, contains 1.5 to 2.5% of rotenone.

Lonchocarpus (*B.P.C. Supp. V*). Determined by the method for Derris, contains not less than 2% of rotenone.

The value of derris root as an insecticide is now assessed upon a combination of rotenone and total ether-soluble extract contents.—G. A. Freak, *Chem. & Ind.*, 1942, 430.

Determination of Rotenone. The powdered material is mixed with 5% of decolorising charcoal and extracted by percolation with ethyl acetate. Percolation is carried out in percolators which slide inside other metal tubes which are permanently fixed in the water jacket. The drawn out ends of the percolators pass through rubber stoppers into filter flasks immersed in cold water. The diameter of the percolators is about $\frac{3}{4}$ in. for 10 to 20 g. of material, 1 in. for 20 to 40 g., and $1\frac{1}{2}$ in. for 40 to 100 g., each percolator being about 18 in. long. In the tapering ends of the two larger tubes, Gooch crucible discs are placed on which rest discs of filter-paper with a wad of cotton wool. The amount of material used for extraction should be sufficient to yield about 1 g. of rotenone. After extraction a weighed quantity of pure rotenone is added to the resins sufficient to bring the proportion present to at least 40%, and 1 g. is added if the amount present is already up to or above 40%, and the whole is warmed and mixed and then left overnight in a desiccator containing carbon tetrachloride. The crystals are broken up, washed with solution of rotenone in carbon tetrachloride until no further colour is obtained and dried at about 40° for 6 hours. The purity of the crude carbon tetrachloride complex varies between 91 and 96%; the mean value, 94%, may be used in approximate routine work. The purity can be accurately determined by triturating the complex with a saturated solution of rotenone in dehydrated alcohol, leaving the mixture overnight in a desiccator containing alcohol, filtering, washing with alcohol, drying at 100° and weighing.—R. R. le G. Worsley, *J. Soc. chem. Ind., Lond.*, 1936, 349T. See also *ibid.*, 1937, 13T, 175T.

Although there is usually good agreement, occasionally large differences occur between the results of carbon tetrachloride extraction and cold chloroform extraction, and the former cannot be relied on to extract the rotenone completely. The following process is based on that of Beach (*Soap*, 1936, 12, 109). 30 g. of powdered root is shaken for 2 hours with 300 ml. of chloroform, then left overnight and shaken for another hour. Alternatively, the mixture is shaken for a short time, left overnight, shaken by hand at intervals during the next day and then on the following day for a short time before continuing the assay. The liquid portion is poured off into a filter funnel large enough to hold sufficient to give 200 ml. of filtrate and the funnel is covered with a clock-glass. The filtrate is collected in a 200 ml. graduated flask, precautions being taken to avoid evaporation. The chloroform is removed from the filtrate by distillation until about 50 ml. remains; this is removed practically completely on the water-bath, the last traces being removed by heating on the water-bath under reduced pressure. 10 ml. of carbon tetrachloride is added and removed, first on a boiling water-bath and then at a lower temperature with a vacuum pump, the process being repeated with 5 ml. of carbon tetrachloride. The residue is dissolved in 15 to 25 ml. of carbon tetrachloride saturated at 0° with rotenone, the solution cooled, seeded if necessary with a crystal of rotenone-carbon tetrachloride complex and set aside in a cool place for 2 days, then in ice for 3 hours. The crystals are then filtered off and weighed. The error due to change in volume of the chloroform due to dissolution of the extracted matter is small and its effect is somewhat compensated by evaporation of the chloroform during filtration. The purity of the rotenone complex may be ascertained if required by determining the specific rotation of a 5% w/v solution in benzene. The pure complex gives a rotation of -16.25°

and it is sufficiently accurate to assume that the purity is proportional to the rotation. In the so-called Sumatra type of derris root there is no crystallisation of complex even on storing at 0°, and in these cases 2 g. of pure rotenone complex must be added to the extract from 40 g. of root.—W. M. Seaber, *J. Soc. chem. Ind., Lond.*, 1937, 168T.

The following method, recommended for inclusion in the B.P.C., is based upon the work of H. E. Coomber, J. T. Martin, and S. H. Harper (*J. Soc. chem. Ind., Lond.*, 1942, 111):—

Weigh accurately 20 g., in moderately fine powder, and extract for three hours by continuous extraction with boiling chloroform; remove most of the chloroform and transfer the residual solution to a 100 ml. conical flask, washing out the extraction flask with carbon tetrachloride, and evaporate almost to dryness on a water-bath in a current of air and, finally, for about five minutes under reduced pressure. Dissolve the extract in 15 ml. of hot carbon tetrachloride, evaporate off the solvent as before and repeat the solution and evaporation with a further 10 ml. of carbon tetrachloride. To the residue add 25 ml. of carbon tetrachloride saturated at 0° with pure rotenone and dissolve by heating gently under a reflux condenser, cool in ice for ten minutes, add one or two small crystals of rotenone-carbon tetrachloride compound if necessary and rotate the flask until crystallisation is apparently complete. If only a small quantity of crystalline matter separates dissolve 1 g., accurately weighed, of pure rotenone in the solution and repeat the crystallisation, deducting in the calculation of the result of the assay the weight of pure rotenone added. Place the flask in ice and allow it to stand at 0° overnight. Filter off the crystals in a suitable weighed crucible, wash the flask and crystals with 15 ml. of ice-cold carbon tetrachloride saturated with rotenone and dry the crucible with its contents at 40° for one hour. Add 25 ml. of dehydrated alcohol saturated at 0° with pure rotenone to the contents of the stoppered crucible, break up the crystalline mass by stirring and allow the closed crucible and contents to stand at 0° for four hours; remove the alcohol by suction, wash the residue of rotenone at 0° with 10 ml. of the dehydrated alcohol saturated with pure rotenone, dry at 105° and weigh. Remove the crystals, mix well, dissolve 1 g., accurately weighed, in sufficient benzene to produce 25 ml. at 20° and determine the optical rotation in a 10-cm. tube at 20°. Calculate the purity of the rotenone obtained by multiplying the observed rotation in degrees by 100 and dividing by 9.04, and calculate the percentage of pure rotenone in the sample after making allowance for the rotenone added during the process of the assay. *Note*:—The saturated solution of rotenone in carbon tetrachloride is prepared by dissolving 2.72 g. of pure rotenone in hot carbon tetrachloride, cooling, and making up to 1000 ml. at 0°. The saturated solution of rotenone in alcohol is prepared by dissolving 1.244 g. of pure rotenone in absolute alcohol and making up to 1000 ml. at 0°.

Commercial samples examined by the carbon tetrachloride process have been shown to contain from nil to 6.9% of rotenone.—*Bull. imp. Inst., Lond.*, 1933, 32, 469.

The carbon tetrachloride method of determining rotenone gives results which are low if the rotenone content of the resin (either isolated or present in the root) is below about 17%, and is seriously in error if the rotenone content of the resin is below 10%. It fails completely for resins of very low rotenone content. A resin may contain up to 15% of rotenone, i.e., 2.4% of rotenone in the root, and yet give no rotenone by the standard method of determination. The rotenone-carbon tetrachloride crystals which separate in the determination of rotenone are at most 90 to 95%, probably only 80 to 90%, pure.—R. S. Cahn and J. J. Boam, *J. Soc. chem. Ind., Lond.*, 1935, 37T.

Determination of rotenone in derris root.—Th. M. Meijer and D. R. Koolhaas, *Industr. Engng. Chem. (anal. Edn.)*, April, 1940, 205.

Approximate Colorimetric Determination. The violet colour produced by the action of strong sulphuric acid containing nitrite on derris extract is proportional to the ether extract. 1 g. of air-dried derris powder is shaken for five minutes with 10 ml. of acetone. The suspension is then filtered, and 1 ml. of the filtrate is diluted to 25 ml. with distilled water. 0.2 ml. of the milky solution is pipetted into a dry test-tube and treated with 5 ml. of a 10% solution of sodium nitrite in strong sulphuric acid, added slowly. The intensity of the colour is measured in a Pulfrich "Stufenfotometer" with a S53 (wave length 550) filter. The percentage of ether extract can be calculated from these measurements. An approximate determination without the use of a photometer may be

made by employing solutions of cobalt chloride in water and in alcohol as colour standards. These solutions are stable if kept in sealed tubes.—T. M. Meijer, per *Quart. J. Pharm.*, 1937, 86.

Direct insecticidal tests show that no single chemical method of assay truly assesses the relative potencies of derris. The toxicity is determined not only by the rotenone content but by the precursors of deguelin and toxicarol also.—*Rothensted Experimental Station Report for 1935*, p. 58.

Constituents. In addition to rotenone, a dimorphic substance (m.p. 189° and 192° to 194°), isomeric with tephrosin, $C_{13}H_{12}O_7$, and having insecticidal properties, has been isolated from derris. Published data on the relative toxicities of rotenone, deguelin, tephrosin, and toxicarol are inapplicable to the assessment of the toxicity of derris resin, as the last three compounds do not occur as such (or, at most, in very small amounts) in derris resins. The conclusion, often drawn from published data, that the value of a derris root or resin can only be assessed by its rotenone content, is quite unjustified.—R. S. Cahn and J. J. Boam, *J. Soc. chem. Ind., Lond.*, 1935, 42T.

The toxicity is due to rotenone, deguelin and an unidentified compound. The latter is crystalline and is levorotatory in benzene. When treated with alcoholic potash it gives a high yield of optically inactive toxicarol. It has one-tenth the insecticidal power of rotenone. **Stability.** Derris is stable for years in tins stored under dry, cool conditions. Exposure to light causes loss of activity.—J. T. Martin, *J. Soc. chem. Ind., Lond.*, 1937, 79T.

Rotenone

Colour Test. To 1 ml. of solution in acetone add 1 ml. of diluted nitric acid (1 part acid and 2 parts water) and allow to stand for 30 seconds. Dilute with 8 or 9 ml. of water and add 1 ml. of strong solution of ammonia. A blue colour is produced with 0.0001 g. of rotenone.—H. A. Jones and C. M. Smith, *Industr. Engng Chem. (anal. Edn.)*, 5, 1, 75.

The purity of commercial rotenone can be determined colorimetrically by means of the red colour produced when nitric acid and sodium nitrite are added to a mixture of a solution of the sample in acetone and an equal volume of 10% solution of potassium hydroxide in 95% alcohol. Standard conditions must be employed.—C. R. Cross and C. M. Smith, *J. Ass. off. agric. Chem., Wash.*, 1934, 17, 336.

Detection and Determination of Rotenone in Insecticides. 1 to 2 ml. of sample is diluted to 5 ml. with chloroform, 5 ml. of 10% solution of thymol in chloroform is added, followed by 3 ml. of a mixture of nitric acid 0.2 ml. and hydrochloric acid 100 ml. In the presence of rotenone a bluish-green to blue colour develops on shaking for about 30 seconds.

Determination. A. To 10 ml. of a chloroformic dilution of the insecticide containing 0.05 to 2.5 mg. of rotenone per ml. is added 10 ml. of thymol 10% in chloroform and 2 ml. of a mixture of 100 ml. of hydrochloric acid with 2.5 ml. of solution of hydrogen peroxide. After shaking for 1 minute the mixture is exposed to ultraviolet light. A greenish-blue coloration appears in 15 minutes and after 30 minutes the colour is compared with that produced by known quantities of rotenone similarly treated.

B. The insecticide is diluted with acetone instead of chloroform as in the above test, and the thymol solution is also prepared with acetone. 10 ml. of the thymol solution is added to the insecticide dilution, followed by 0.1 ml. of solution of hydrogen peroxide and 5 ml. of hydrochloric acid. The mixture is warmed to 20° by immersion in warm water and the colour produced after 20 minutes is compared with that obtained by similarly treating known amounts of rotenone. In the presence of kerosene or extracts of pyrethrum, similar additions should be made to the standards.—H. D. Rogers and J. A. Calamari, *Industr. Engng Chem. (anal. Edn.)*, 1936, 135.

A survey of the correlation of toxicity and optical activity of derris derivatives.—R. S. Cahn, *J. Soc. chem. Ind., Lond.*, 1936, 259T.

Toxic Constituents of derris root.—T. A. Buckley, *J. Soc. chem. Ind., Lond.*, 1936, 285T.

DEXTROSUM

Dextrosom (B.P.). $C_6H_{12}O_6=180.1$. Loses not more than 2.5% at 105°, and then a well-boiled 10% w/v solution has a specific rotation of not less than +52°. Residue after ignition and

re-ignition with sulphuric acid, not more than 0.1%. Dextrosum, U.S.P. XII, loses 8 to 10% at 100°. Ammonia solution is added to the solution for the α_D determination, which on the dried substance is +52.5° to +53.0° at 25°. Dextrose which does not conform to the official limits for moisture may be used for the preparation of aqueous solutions, provided it meets all other requirements and allowance is made for the different water content. The moisture limits of 8 to 10% are determined at 100°. Glycosum, P. Helv. V, is pure anhydrous dextrose containing not more than 1% of moisture.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined dextrose as the product chiefly made by the hydrolysis of starch or a starch-containing substance, followed by processes of refining and crystallisation. *Anhydrous dextrose* was required to contain not less than 99.5% of dextrose and not more than 0.5% of moisture. *Hydrated dextrose* was required to contain not less than 90% of dextrose and not more than 10% of moisture including water of crystallisation. *Glucose*, mixing glucose, confectioner's glucose, was described as a thick, syrupy, colourless product made by incompletely hydrolysing starch, or a starch-containing substance, and decolorising and evaporating the product and was required to contain on a basis of 41° Baumé, not more than 1% of ash, chiefly chlorides and sulphates.—S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.

Reducing Sugars.

Determination. The method is based on the reduction of an alkaline solution of potassium ferrocyanide and titration of the resulting ferricyanide with ceric sulphate, using *o*-phenanthroline ferrous sulphate as indicator. Approximately N/100 ceric sulphate is prepared by dissolving the required amount of ceric sulphate in 500 ml. of water to which 100 ml. of a 1 to 1 sulphuric acid solution has been added, and diluting to 1 litre. A 0.025M solution of the indicator is prepared by dissolving 0.695 g. of crystalline ferrous sulphate and 1.485 g. of *o*-phenanthroline monohydrate in water to 100 ml. The alkaline ferrocyanide solution contains 4 g. of potassium ferrocyanide and 24 g. of sodium carbonate per litre. The ceric sulphate is standardised against pure anhydrous dextrose. 10 ml. of a solution containing between 5 and 10 mg. of glucose is warmed on a steam-bath with 25 ml. of the alkaline ferrocyanide solution for exactly ten minutes, the solution is cooled to room temperature, 10 ml. of 5N sulphuric acid and 2 drops of the indicator are added, and the solution is titrated with the ceric sulphate solution. A correction has to be made for the volume of the ceric sulphate solution required by the indicator, which is obtained by a blank titration. If used for the determination of reducing sugars in a plant extract the latter must be clear and colourless. This is obtained by extracting the plant material with alcohol (80%), evaporating to a low bulk, adding a saturated solution of neutral lead acetate and removing the excess of lead by disodium phosphate; decolorising charcoal is added and, after allowing to stand for thirty minutes with occasional stirring, the mixture is filtered through a thin layer of talc on a filter paper. The extract is diluted to a definite volume so that 10 ml. of the dilution will not contain more than 10 mg. of reducing sugar. For the determination, 10 ml. of the dilution is treated as in the above standardisation of the reagent. For the determination of the sucrose 50 ml. of the plant extract is neutralised to the red colour of methyl red with acetic acid, 2 to 4 drops of a 1% solution of Wallerstein invertase scales are added and the solution allowed to stand for two hours at 28°. The solution is then diluted to the required volume and the reducing sugars in 10 ml. determined. As the invertase solution has a slight reducing action it is necessary to carry out a blank determination on this reagent.—W. Z. Hassid, *Industr. Engng Chem. (anal. Edn.)*, 1936, 138.

Reducing sugars may be determined quantitatively by titration of boiling alkaline solution with potassium ferricyanide containing methylene blue as indicator. The method has also been used for sucrose, lactose in milk, glucose in urine and mixtures of maltose and glucose.—S. W. Cole, *Biochem. J.*, 1933, 723.

The potentiometric estimation of glucose with potassium ferricyanide in sodium carbonate solution gives a greater accuracy as compared with Fehling method.—H. T. S. Britton and L. Phillips, *Analyst*, 1940, 149.

Fructose.

Iodometric Determination. The method is based upon the reduction of a solution of copper carbonate. After the reduction the precipitated cuprous oxide is removed by filtration and the cupric ions in the filtrate determined by the addition of sulphuric acid and potassium iodide and titration of the liberated iodine with sodium thiosulphate; from a blank titration of the volume of reagent used the extent of the reduction can be calculated. The reagent is prepared by dissolving 250 g. of potassium carbonate in 700 ml. of hot water and adding 100 g. of potassium bicarbonate in small quantities; when solution is complete a solution containing 15 g. of copper sulphate is added and the solution diluted to 1 litre after cooling to 15°. The determination is carried out by adding 20 ml. of the fructose solution to 50 ml. of the reagent, and warming the mixture at 49° in a stoppered bottle for 2½ hours. The mixture is cooled and diluted to 100 ml.; it is filtered and, after rejecting the first 25 ml. of the filtrate, 50 ml. of the filtrate is acidified with sulphuric acid, potassium iodide added and the liberated iodine titrated with N/10 sodium thiosulphate. A blank titration on 50 ml. of the copper reagent is made. The quantity of fructose present in the 20 ml. of solution is given by the following formula:

$$x = \frac{n + 0.7}{0.26} \text{ mg.}$$

in which n is the difference between the blank and actual titrations. The presence of small quantities of glucose does not interfere with the determination. —S. Streptkoff, per *Quart. J. Pharm.*, 1937, 88.

Glucosum Liquidum (B.P.). n_{D20° , not less than 1.490. Ash, not more than 0.6%. Sulphur dioxide limit, 450 parts per million. By evaporation with water and drying at 90°, Glucosum Liquidum, *U.S.P. XII*, loses not more than 21% of its weight; ash, not more than 0.5%.

Determination of Glucose. 0.2 ml. of sample is added to 1.6 ml. of N/12 sulphuric acid and 0.2 ml. of a 10% solution of sodium tungstate; the mixture is well stirred, allowed to stand for five minutes and then centrifuged. 1 ml. of the clear liquid, equivalent to 0.1 ml. of blood, is heated with 1 ml. of Fehling's solution in a boiling water-bath for 30 minutes. The precipitate is separated by centrifuging, washed four times with 2 ml. of distilled water, and dissolved in 2 ml. of aqua regia, and the solution is made alkaline with ammonia and filtered. The filter is washed with water containing a little ammonia and the filtrate made up to 100 ml. Using 5 or 10 ml. of the solution the copper content is determined colorimetrically against a standard copper solution containing not more than 0.05 mg. of Cu. As some auto-reduction of the Fehling's solution takes place, a blank determination is made.—E. Lasausse *et al.*, *J. Pharm. Chim.*, Paris, ii/1936, 461.

Lactosum (B.P. Add. I). $C_{12}H_{22}O_{11} \cdot H_2O = 360.2$. A 10% w/v boiled solution has a specific rotation, determined at 20°, of +52° to +52.6°. Ash, not more than 0.1%. Tests for more soluble sugars, copper and acidity are included. Limit of matter soluble in 4 parts of alcohol (90%), 0.2% (limit of more soluble sugars). Lactosum, *U.S.P. XII*, should leave not more than 0.1% of ash, and should comply with tests for sucrose, dextrin and starch, and for dextrose.

Lævulosum (B.P.). $C_6H_{12}O_6 = 180.1$. Determined at 20° on a well-boiled 10% w/v aqueous solution, the specific rotation should be not less than -81°. Loss at 105°, not more than 5%. Sulphated ash, not more than 2.5%.

Mel Depuratum (B.P.). Sp. gr. 1.359 to 1.361. α_D for a 20% w/v decolorised solution, +0.6° to -2°, corresponding to a specific rotation of +3° to -10°. Ash, not more than 0.3% w/w. Artificial invert sugar is excluded by adding one drop of

resorcinol in hydrochloric acid solution to an evaporated ethereal extract, when no persistent cherry-red or brown-red colour should be produced. Mel, *U.S.P. XII*, has a sp. gr. of not less than 1.099 at 25° when diluted with twice its weight of water and should comply with tests for acidity, starch or dextrins, foreign colouring matter, azo dyes, and with the following test for artificial honey or added invert sugar:—

If 1 g. of honey be triturated with 20 ml. of ether in a mortar, filtered, the filtrate allowed to evaporate, and 1 drop of a 1% resorcin solution in hydrochloric acid added, a pink colour may form which disappears in half a minute, but an orange, cherry or brown-red colour must not be produced.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined honey as the nectar and saccharine exudations of plants gathered, modified and stored in the comb by honeybees (*Apis mellifica* and *A. dorsata*). Was required to be lavorotatory and to contain not more than 25% of water, not more than 0.25% of ash, and not more than 8% of sucrose. Comb honey is contained in the cells of comb. Extracted honey is separated from the uncrushed comb by centrifugal force or gravity. Strained honey is removed from the crushed comb by straining or other means.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

Sucrosom (B.P.). $C_{12}H_{22}O_{11}=342.2$. Specific rotation in 10% *w/v* solution, +66° to +66.7°. Ash, not more than 0.05%. The absence of ultramarine should be indicated by the absence of unpleasant odour in one hour on the addition of dilute hypophosphorous acid to the clear, colourless, odourless solution. The *U.S.P. XII* determines the specific rotation on a 26% *w/v* solution of Sucrosom dried at 105°, and in a 200 mm. tube; it should not be less than +65.9°. The *Fr. Cx.* 1937 requires a 16.29% solution of the dry substance in a 2 dm. tube to have a rotation not less than 21.6°.

Sucrose may (in the absence of a polarimeter) be approximately estimated by heating 1 g. in 50 ml. of water, to which 10 drops of hydrochloric acid have been added, for half an hour on a water-bath. The solution is then cooled and neutralised with soda and made up to 100 ml. with water, and the invert sugar thus formed is estimated with Fehling's solution, 1 ml. of which is approximately equivalent to 0.005 g. of invert sugar, the calculation being on the basis that 360 of invert sugar represents 342 of cane sugar.

Determination of Invert Sugar in Cane Sugar. *U.S.P. XII* gives the following: Dissolve 20 g. sucrose in enough distilled water to make 100 ml.; filter if necessary. To 50 ml. of the clear liquid add 50 ml. of alkaline cupric tartrate solution: heat the mixture so that 4 minutes are required to bring it to boiling point and boil for 2 minutes. Add 100 ml. of cold recently boiled distilled water, and collect and weigh the precipitated cuprous oxide as follows. Prepare a Gooch crucible with an asbestos layer. Wash the asbestos with distilled water, followed successively by 10 ml. of alcohol and 10 ml. of ether, dry at 100° for 30 minutes and weigh the crucible. Filter the precipitated cuprous oxide through the crucible, wash the residue on the filter with hot distilled water, then with 10 ml. of alcohol, and then with 10 ml. of ether, and dry at 100° for 30 minutes. The weight of cuprous oxide does not exceed 0.112 g., corresponding to not more than 0.3% of invert sugar.

DIGITALIS

Digitalis Folium (B.P. Add. I). Should contain not more than 2% of foreign organic matter, lose not more than 8% at 100°, and leave not more than 5% of acid-insoluble ash. Digitalis, *U.S.P. XII*, contains not more than 2% of browned leaves, stems, flowers,

or foreign organic matter; acid-insoluble ash, not more than 5%; moisture not more than 6%; activity of 0.1 g. equivalent to not less than one U.S.P. Digitalis Unit (equivalent to the International Digitalis Unit of 1928). *Folium Digitalis*, *P. Helv. V*, consists of the leaves of *Digitalis purpurea* Linn., collected when dry, dried immediately at 40° and then for 30 minutes at 55° to 60°. Moisture, not more than 1%; ash, not more than 10%; acid-insoluble ash, not more than 4%. Powdered digitalis consists of the powder of the whole leaf prepared without any residue and is not standardised biologically or chemically.

Digitalis Lanata. The leaves of *Digitalis lanata* Ehrh. have become a regular article of commerce; their physiological activity has been investigated by a number of workers, and the results published show that they have an activity which is from two to five times as great as that of the leaves of *D. purpurea* Linn. The following characters enable the leaves to be distinguished from those of *D. purpurea*. The cells of both epidermises have anticlinal walls which are distinctly beaded. The non-glandular trichomes are uniseriate, consisting usually of from 10 to 14 cells; they are confined almost exclusively to the margins of the leaves. The paucity of the non-glandular trichomes causes the leaves to appear almost glabrous. Water pores occur singly or in groups consisting commonly of two pores.—T. Dewar, *Quart. J. Pharm.*, 1934, 331.

Constituents. Digitalis contains several glycosides, to which its physiological activity is due; of these, digitoxin, $C_{41}H_{64}O_{13}$, and gitoxin, $C_{41}H_{64}O_{14}$, have been obtained crystalline. A third glycoside, $C_{47}H_{72}O_{18}$, is described as having the composition of digitoxin with the addition of one molecule of dextrose; it is hydrolysed by the enzymes of the leaf into digitoxin and dextrose. The remaining glycosides have not been obtained in a state approaching purity; they are amorphous and more soluble than the crystalline glycosides. The latter are very sparingly soluble in water, but become more soluble in the presence of the amorphous glycosides. Distinctive names have been given to various mixtures, but only the two above-mentioned glycosides are definite substances. Gitalin and digitalein are mixtures of indefinite composition. Anhydrodigitalin is a crude form of gitoxin. Digitalis seeds do not contain digitoxin or gitoxin, but contain a closely-related glycoside, digitalinum verum, $C_{58}H_{88}O_{14}$, associated with a large proportion of water-soluble glycosides and two physiologically-inactive glycosides, digitonin, $C_{54}H_{86}O_{12}$, and gitonin, $C_{54}H_{86}O_{12}$. Digitalinum verum is not crystalline, but it forms crystalline derivatives. A standardised mixture of glycosides prepared from the seeds is known as digitalin, or digitalinum purum germanicum.

A preparation of the glycosides representing about 74% of the total activity of the original leaf may be obtained by extracting the leaf with benzene. The residue is extracted with alcohol, and benzene added followed by water. The aqueous-alcoholic layer is concentrated by means of chloroform followed by precipitation of the glycosides with light petroleum.—E. Hesse, W. Altner and J. Becher, *Klin. Wschr.*, 1933, 12, 1862.

Fresh concentrated infusions made with 20% alcohol or 0.1% chloroform water are essentially digitoxin preparations, whereas the fresh B.P. infusion is a digitalein preparation. Old concentrated infusions showed absence of therapeutic value in the filtrate with presence of toxic effects, the sediment being also toxic and possessing tonic effect.—K. Samaan, *Pharm. J.*, i/1921, 481.

Differentiation of Cardiac Glycosides. Digitoxin warmed for 3 minutes on a water-bath with 2 drops of glacial acetic acid and 10 drops of 0.3% w/v solution of vanillin in hydrochloric acid gives a permanent indigo blue colour; strophanthin-k gives a non-persistent deep blue precipitate, soluble in more acetic acid. Digitoxin in solution can be extracted before applying the test, by shaking with chloroform after rendering the solution alkaline with borax, drying and evaporating the chloroformic solution. Ouabain evaporated to dryness on a water-bath with 1 ml. of a solution of 0.1 g. of dimethylamino-benzaldehyde in 20 ml. of alcohol (95%) containing 4 drops of sulphuric acid gives a residue which is coloured violet when moistened with acetic acid. German digitalin under similar conditions gives an eosin-red colour. Digitoxin can be distinguished from German digitalin by addition of a reagent containing 1 drop of saturated bromine water in 20 ml. of sulphuric acid. German digitalin gives

a bright red, digitoxin shows no change.—J. A. Sanchez, *J. Pharm. Chim., Paris*, ii/1936, 549.

Stability. Digitalis dried at 100°F. immediately after harvesting is very stable in activity over a period of six years. Defatting slightly improves stability but air-tight and light-tight storage is entirely unnecessary. About 25% of the activity of the fresh drug may be lost during commercial drying.—L. W. Rowe and H. W. Pfeifle, *J. Amer. pharm. Ass.*, 1936, 855.

Martindale's Chemical Assay for Digitalis.

The determination of the value of a digitalis preparation (especially the tincture) by chemical means is fraught with considerable difficulties owing to many factors, e.g., the numerous glycosidal bodies contained, the fact that it is not possible to point to one glycoside as the potent constituent responsible for the activity of the drug, and again, the extraction of the substances in any degree of purity requires some analytical skill.

A tincture having by physiological tests a m.l.d. calculated as 0.75 ml. per 100 g. weight of frog was adopted as a standard.

In a paper read before the Pharmaceutical Society of Great Britain, Dec. 10, 1912, the results of examination were provided of a number of samples of leaves from various parts of the world (Great Britain, Germany, Italy, India, etc.). Almost all of these leaves gave tinctures of standard, or above standard, strength. (The paper was later published in a booklet entitled "*Digitalis Assay*.")

The colorimetric method devised was claimed by Martindale to give results equivalent to the physiological assay method based on the minimum lethal dose required to kill a frog and calculated to 100 g. body weight. The method requires some care in carrying out, as it is strictly quantitative. It is as follows:—

To determine whether a tincture is up to physiological test requirements (usually taken at m.l.d. = 0.75 ml. per 100 g. body weight of frog) mix 10 ml. of the tincture with 10 ml. of water, precipitate with 10% neutral lead acetate solution (about 3 ml.), adding a little diatomite. Allow to stand for 15 minutes, filter off on the pump and wash the precipitate slightly. Remove excess of lead from the filtrate with 10% sodium phosphate solution (about 2 ml. required) and filter. Add a little calcium carbonate (about 0.2 g.) to the filtrate (to prevent possible hydrolysis of the glycosides), and evaporate to dryness on a water-bath. Add about 2 g. of dry washed sand to the residue and extract with chloroform five times by thorough trituration, using about 10 ml. on each occasion. Filter and evaporate the chloroformic solution and extract the residue with warm water on the water-bath, using 10 ml. and 5 ml. and again employing sand. Filter, evaporate to dryness in a porcelain basin, extract the residue again with cold chloroform to purify it (about three or four quantities of 5 ml. each, using dry sand and triturating thoroughly with a small pestle) and filter. Evaporate the combined chloroformic liquors and dissolve the residue in 4 ml. of glacial acetic acid. Mix 0.1 ml. of this acetic solution with 1 ml. of sulphuric ammonium molybdate reagent in a 5 × 1 cm. test-tube and compare the depth of colour after five minutes with that produced with 10 ml. of the standard tincture, mounting the tubes on a little slab of plasticine and observing the colours by direct transmitted light using a white background. This coloration indicates the content of combined "active water-soluble" glycosides (probably including digitoxin). Further, if 0.1 ml. of the acetic solution be mixed with 0.5 ml. of glacial acetic acid, and this be layered upon 1 ml. of the sulphuric ammonium molybdate reagent, the typical blue ring showing presence of digitoxin should be formed.

Chemical assay processes used in the past centred on an estimation of the digitoxin—ignoring the bodies which are known to be readily soluble in water. That this was fallacious was shown by Ziegenbein, who found that leaves containing only 0.125% of this glycoside were twice as active as those containing 0.226%.

The above method includes the latter in addition to digitoxin or an allied body. The process includes a strong indication of digitoxin—either through the actual solubility of it in the repeated quantities of solvent (the amount of digitoxin in 10 ml. of tincture is extremely minute though sufficient to detect), or owing to the fact that digitoxin is soluble in the presence of the other glycosides and saponins. Results approximating the physiological m.l.d. results were obtained with the samples of tinctures referred to, even after 12 months' storage.

Tschirch confirms Ziegenbein's findings that the digitoxin content in digitalis leaves is not in proportion to the physiological activity. It was found that chloroform must be used repeatedly (eight shakings) to remove the entire active substances.

Absolute alcohol, acetone and amyl alcohol will exhaust leaves completely; chloroform, acetic ether and benzene partially. Ether and carbon tetrachloride do not extract the active substances at all. Acetone is especially good as yielding a colourless extractive. It can be used for assaying. (The use of acetone instead of chloroform in Martindale's method might yield interesting results.)—Tschirch & Wolter, *Schweiz. ApothZtg.*, 56, 469; per *Pharm. J.*, 1/1919, 219.

A comparison of the results of the biological assay and the colorimetric assay of Knudson and Dresbach on nine samples of leaves from 4 different species showed very close agreement. In the colorimetric process referred to, the infusion of the sample is precipitated first with lead acetate and then with sodium phosphate, and the filtrate is treated with sodium picrate. The colour produced is compared with that given by a standard solution of ouabain. In place of the latter, the authors used a solution of potassium dichromate.—B. J. Oikeloën and J. C. Timmer, *Pharm. Weekbl.*, 1931, 68, 820.

Method found unreliable.—J. A. C. Pinxteren, *ibid.*, 1932, 69, 4.

Only one out of fifteen samples assayed by the method of Knudson and Dresbach agreed with the biological (frog) assay.—F. J. Dyer, *Quart. J. Pharm.*, 1932, 172.

Digitalis Pulverata (B.P.). Adjusted for therapeutic administration to contain 10 units in 1 g. Loss at 100°, not more than 8%.

BIOLOGICAL METHODS OF ASSAY

The potency of powdered digitalis, *B.P.*, is determined by comparing each sample with a standard preparation of powdered digitalis which is distributed by the National Institute for Medical Research, Hampstead. The strength of the standard preparation has been carefully determined by comparison with the international standard digitalis powder. When an unknown sample has been compared with the standard preparation, its potency can then be expressed in terms of the international standard, that is to say, a statement can be made as to how much stronger or weaker the sample is than an average sample. To make this statement short, the international standard is arbitrarily described to contain 10 units of activity in 0.8 g.

Samples of powdered digitalis for therapeutic administration must be adjusted to contain 10 units per g. The maximum dose for repeated use is given as 0.1 g., or 1.5 grains, which is 1 unit, while the maximum single dose is 0.6 g., or 10 grains, which is 6 units. *B.P.* permits any method of assay to be used which is based on the effect of digitalis on cardiac muscle, or which gives results parallel to those obtained on cardiac muscle. *B.P.* suggests the frog method and gives instructions for performing it.

The Frog Method. The standard preparation and the unknown sample are extracted by a suitable method, for example tinctures of each are prepared with 70% alcohol. The tinctures, diluted with saline, are injected into two groups of frogs, which are as nearly as possible alike. The proportion of frogs killed in 24 hours by a given dose of the standard tincture and the proportion killed by a given dose of the unknown are then determined. Now, the relative potency of doses killing different proportions of frogs has been investigated on large numbers of frogs (Trevan, *Proc. roy. Soc.*, Ser. B, 1927, 101, 483) and a table showing these relative potencies is given in *B.P.* For

example, if the dose which kills 50% is taken as 100, then experiment has shown that the dose killing 30% is 87. By means of this table the potency of the unknown tincture is related to that of the standard. *B.P.* '32 requires that not less than 50 frogs be used in the comparison, since the standard deviation, that is to say, the error in two-thirds of the tests, will then not be greater than 10%. Likewise, the error in twenty-one out of twenty-two tests will not be greater than 20%.

The South African clawed frog or toad, *Xenopus laevis*, was found to respond more constantly than species of *Rana* to the digitalis series of drugs and is recommended for use in the biological assay of digitalis.—J. W. C. Gunn and D. Epstein, *Quart. J. Pharm.*, 1932, 180.

The Cat Method. The cat method differs from the frog method in that the minimum lethal dose for each cat is determined. Much confusion has arisen due to the incorrect use of this term; when a single dose of digitalis is injected into a frog, or of another drug into another animal, the animal either dies or survives, and it is impossible to say whether the dose was the minimal lethal dose or not; it is only possible to discover with accuracy the dose killing a certain proportion of animals, for none of which it may be minimal. The term L.D. 50 was introduced by Trevan to indicate the "mean lethal dose" which kills 50%. The expression "minimal lethal dose" should be reserved for those estimations in which the least amount of a substance necessary to kill is actually determined, of which the administration of digitalis to a cat is an example. As in the frog method both the standard preparation and the unknown sample of powdered digitalis are extracted by a suitable method; a 0.5% hot water infusion (90° for 15 minutes) is convenient. The extract is placed in a burette from which it is allowed to flow at a slow constant rate into the vein of an anæsthetised cat. The time of inflow is usually from 30 to 45 minutes, at the end of which period a concentration of the digitalis glycosides reaches the heart sufficient to produce arrest in systolic contraction. Throughout the experiment the cat is given artificial respiration to ensure that death does not occur from respiratory failure. The amount of extract administered up to the time of cardiac arrest is recorded, and a calculation made to determine the amount per kg. body weight. The figures for a series of cats are obtained both for the standard extract and for the unknown extract. *B.P.* 1932 requires that the standard extract be tested on 14 cats and the unknown on 6 cats; with these numbers the error of the estimation is then about the same as in the frog method. The test of the standard extract is not repeated each time an unknown extract is tested; it is sufficient to test the standard extract once a year, as cats do not vary in sensitiveness at different times. The average minimal lethal dose of a 0.5% hot water infusion of the international standard digitalis powder is 18.0 ml. per kg. cat. This corresponds to 90 mg. per kg. of the powder itself, but the figure varies according to the composition and amount of the

anæsthetic used. (See Macdonald, *Quart. J. Pharm.*, 1934, 182). While 90 mg. per kg. is the figure for cats under light anæsthesia with ether, 75 mg. per kg. is the figure for cats fully anæsthetised with ether.

Ether is an unsuitable anæsthetic for use in the assay of digitalis by the cat method in the tropics, but identical results are obtained when other anæsthetics are used, provided an uninterrupted and uniform depth of anæsthesia can be obtained without any side-effects on the circulation or respiration.—J. C. David and N. Rajamanickam, *Quart. J. Pharm.*, i/1934, 36.

HATCHER CAT UNIT. Hatcher defined the cat unit of powdered digitalis as the average minimal lethal dose per kg. Thus 1 cat unit of the international standard digitalis powder can be taken as 90 mg., but as seen from the foregoing paragraph, it depends on the amount of anæsthetic. Since 1 international unit is by definition the amount of activity in 80 mg. of the international standard digitalis powder, it may be said that the relation between the Hatcher cat unit and the international unit is 9 to 8, but the relation varies according to the technique of each laboratory.

POTENCY IN INTERNATIONAL UNITS. If the average minimal lethal dose for the 0.5% hot water infusion of the standard is found to be 16 ml. per kg., and if the figure for a similar extract of the unknown sample is 14 ml. per kg., then the potency of the unknown sample is $\frac{16}{14} = 1.14$ times that of the standard. If

the standard preparation is exactly equal to the international standard digitalis powder, then the unknown sample of powdered digitalis contains 11.4 units per 0.8 g.

Guinea-pig Method. The *B.P.* mentions the method of intravenous injection into guinea-pigs, which is in essentials similar to the cat method. It was introduced by Knaff-Lenz (*J. Pharmacol.*, 1926, 29, 407). Animals weighing 400 g. to 700 g. are anæsthetised with urethane, 1.75 g. per kg., injected under the skin. The digitalis extract, in concentration of 1.25%, is allowed to enter the jugular vein at constant rate. The experiment takes about 20 minutes. The method has the advantage that guinea-pigs vary less in sensitiveness to digitalis than cats, and a smaller number give the same accuracy. The *B.P.* '32, however, requires the same number of guinea-pigs as of cats.

Pigeon Method. When one of the cardiac glycosides is injected into the vein of a pigeon, it vomits in the course of 10 to 15 minutes, provided the dose is sufficient. (Hanzlik, *J. Pharmacol.*, 1929, 35, 363; also Burn, *ibid.*, 1930, 39, 221.) Powdered digitalis may be assayed by preparing a tincture and comparing it with a tincture prepared from the standard preparation. A dose of the order of 0.2 ml. of tincture per kg. is injected, the tincture being diluted so that the volume given to a bird weighing 300 g. is about 0.3 ml. The dose is given to each of a group of about twenty-five birds, and the proportion which vomit is observed. This proportion is determined both for unknown and for the standard. The relative potency of unknown and standard is then calculated from data previously obtained. (See Burn, *loc. cit.*)

United States Pharmacopœia XII Method. The frog method of the *U.S.P. XI* has now been replaced by a method using cats. The potency of 0.1 g. is required to be equivalent to not less than 1.0 *U.S.P.* Digitalis Unit when compared with *U.S.P.* Digitalis Reference Standard. One *U.S.P.* Digitalis

Unit is identical in potency with the International Unit as defined by the League of Nations' Commission. The 1942 Digitalis Reference Standard is identical, within the limits of biological error, in potency with the International Reference Standard. The Digitalis Reference Standard of the *U.S.P. XI* was found to be considerably stronger than previously stated and digitalis preparations of the *U.S.P. XI* had a corresponding higher potency. Tincture of digitalis *U.S.P. XI* was found to be 50% stronger than the tincture of the *U.S.P. X*, whereas it had been stated to be 25% stronger. The correction now made in the *U.S.P. XII* results in the fact that powdered digitalis and tincture of digitalis *U.S.P. XII* are weaker than the corresponding preparations of the *U.S.P. XI* and are 125% the strength of those of the *U.S.P. X*.

Dog Method. The use of dogs anaesthetised with Pentobarbital gives results similar to those obtained with frogs. By injecting intravenously the supernatant liquid of the tincture prepared from international powder the L.D. in dogs was shown to be 120 mg. of powder per kg. bodyweight, corresponding to twelve injections of 0.1 ml. of liquid per kg. Experiments with dogs and cats indicated that 0.62 g. and not 0.745 g. as stated, of the reference powder of *U.S.P. XI* is equivalent to 1 g. of international powder.—P. Blickensdorfer and H. A. McGuigan, *J. Amer. pharm. Ass.*, 1940, 101.

Chick Heart Method. A method for the assay of digitalis tincture or whole leaf preparations on the embryonic chick heart. The technique requires no elaborate equipment and no extensive training on the part of the operator and gives results which are at least as close to man as the chick assay.—R. A. Lehman and G. H. Paff, *J. Pharmacol.*, 1942, 75, 207.

Tabellæ Digitalis (*U.S.P. XII*). Contain powdered digitalis corresponding in potency to 95 to 105% of the labelled amount of powdered digitalis. Assayed by preparing a tincture from not less than 20 tablets and completing the assay biologically as described for tincture of digitalis. In the preparation of the tincture, the tablets are triturated with alcohol-water mixture (4:1) until disintegrated, the suspension is transferred to a hard glass-stoppered container and sufficient menstruum added so that 1 ml. may be expected to contain 1 *U.S.P.* unit. The mixture is then shaken mechanically for 22 to 26 hours at 20° to 30° so that the solid material is brought into fresh contact with the liquid phase. The suspension is then centrifuged and the tincture transferred to a well closed container, preserved under refrigeration and assayed within 30 days.

Tinctura Digitalis.

(a) *B.P.* 1 ml. must contain 1 unit of activity. The assay is performed by comparing the tincture with a tincture prepared from the standard preparation (*B.P.*) by one of the methods described for powdered digitalis. The tincture is usually prepared to contain more than 1 unit per ml.; it is then assayed and diluted to exactly 1 unit per ml. The supply of the International Standard Digitalis Powder (containing 1 unit of activity in 0.1 g.) having been exhausted, and a new powder (containing 1 unit in 0.08 g.) having been substituted, the *B.P. Add. I* makes the necessary adjustment for Tinctura Digitalis to possess 1 unit of activity (equivalent to the activity of 0.08 g. of the International Standard Digitalis Powder) in 1 ml. It may also be prepared by a maceration process.

(b) *U.S.P. XII.* The potency is such that, when assayed as directed, 1 ml. of the tincture possesses activity equivalent to 1.0 *U.S.P.* Digitalis Unit.

Digitalinum (*B.P.C.*). Possesses 80 units of activity in 1 g. (equivalent to the activity of 8 g. of the International Standard Digitalis Powder). Assayed biologically by the *B.P.* process for Digitalis Pulverata.

Kiliani Test for Digitalin. Ferric sulphate, 0.05 g., is dissolved in water, 1 ml., and sulphuric acid added to 100 ml. Employed as a mixing test (0.1 mg. of the glycoside is sufficient, dissolved in 0.2 ml. of glacial acetic acid), this reagent produces a pink coloration.

This test with digitoxin produces a brownish colour.

Assay. Digitalin is assayed by one of the methods described for powdered digitalis, in comparison with the standard preparation described in *B.P.* '32. Gage (*Quart. J. Pharm.*, 1933, 161) has found that unstandardised samples vary from 55 to 250 units per gramme. The dose given in *B.P.C.* for the standardised digitalin is $\frac{1}{2}$ to 1 grain for single administration; this corresponds to 2.5 to 5 units; it is injected subcutaneously or intramuscularly, being the only digitalis body which can be given in this way.

Digoxinum (*B.P. Add. V*). $C_{41}H_{64}O_{14}$ = 780.5. M.p. (with decomposition), 265°. α_D of 2% w/v solution in anhydrous pyridine (mercury light), +13.5° to +13.7°. Allied glycosides are limited by addition of sulphuric acid to a 0.1% solution in glacial acetic acid containing 0.01% w/v of ferric chloride, when the pure brown ring at the junction of the liquids should be free from red colour.

Digoxin can be given by mouth or by intravenous injection. Its potency has been determined by White (*J. Pharmacol.*, 1934, 52, 1) on various species. On the cat and the frog it has about one-quarter of the activity of ouabain, and probably contains about 2500 units per gramme. It exerts a cumulative effect when administered by mouth to cats or guinea-pigs.

Assayed biologically by the frog method, 0.6 mg. of digoxin was equivalent to 1 ml. of standard tincture, whereas when assayed by the cat method the equivalent amount was 0.4 mg. Administered orally to patients with auricular fibrillation, single doses of 1 to 2 mg. produced a rapid fall in ventricular rate, and the average subsequent daily dose found necessary was 0.5 mg. It is not necessary to administer digoxin by injection except in exceptional cases.—E. J. Wayne, *Clin. Sci.*, 1933, 1, 63.

Digitoxinum (*B.P.C.*). M.p., not below 240°. Loss at 100°, not more than 1%.

Keller-Kiliani (*Syn. Keller's Test for Digitoxin in the Leaves*). Shake 10 ml. of filtered infusion in boiling water, 1+20, in a separator for a few minutes with chloroform, 10 ml., add ether, 5 ml., and alcohol, 5 ml.; shake again and filter off the chloroform-ether solution through a filter moistened with chloroform. The liquid is evaporated and the residue dissolved in 3 ml. of acetic acid (96%). A drop of diluted solution of ferric chloride (1+19) is added, and the whole, in a narrow test-tube, is layered carefully upon sulphuric acid; at the point of contact of the two liquids a brownish-red zone develops, and over it a bluish-green zone.—*P.G. V*. It has been found in practice that the presence of chlorophyll hinders the coloration considerably.

The test may also be applied to the glycosidal substance *Digitoxin* thus:—Dissolve 0.001 g. in 3 ml. of glacial acetic acid, add a few drops of the ferric chloride solution and proceed exactly as described above.

Froehde's Test (sulphuric ammonium molybdate, see colorimetric method above). Ammonium molybdate, 1% w/v, in concentrated sulphuric acid used as a *mixing* test gives characteristic maroon colour with the water-soluble glycosides. Used as a layering test, it gives a characteristic blue ring.

There is no standard in *B.P.* '32 or in *U.S.P. XI* for digitoxin. Gage (*Quart. J. Pharm.*, 1934, 654) has examined a series of commercial samples in comparison with the standard preparation for powdered digitalis (*B.P.*) by two biological methods, the frog method and the guinea-pig method, and found that their activity varied from 900 to 1200 units per gramme. A pure crystalline sample of Digitaline Native had a potency of 1500 units per gramme.

Convallariæ Radix (*N.F. VII*). Tested by the *U.S.P. XII* method for Digitalis, the potency of 0.1 g. is equivalent to 3 *U.S.P.* Digitalis Units. Foreign organic matter, not more than 5% and acid-insoluble ash, not more than 6%.

Fluidextractum Convallariæ Radicis (*N.F. VII*). The potency of 0.1 ml. is equivalent to 2.75 to 3.25 *U.S.P.* Digitalis Units.

Activity of Tincture. Assays of commercial tincture by the frog method of the Russian Pharmacopœia and by the international cat method gave ranges of 10.5 to 17.6 units per ml. and 1.8 to 3.1 cat units per ml. respectively, with averages of 14.2 units and 2.1 cat units per ml. respectively.—S. I. Ordynskii, per *J. Amer. pharm. Ass.*, 1937, 348.

EPHEDRA

Ephedra (B.P.C.). Contains not less than 1.25% of total alkaloids calculated as $C_{10}H_{15}ON$. Assayed by the B.P.C. process as follows:—Add 200 ml. of ether-chloroform (3 : 1) to 20 g. of the powdered drug, and after 5 minutes, add 10 ml. of dilute solution of ammonia and 1 g. of anhydrous sodium carbonate, shaking frequently for four hours and standing overnight; after percolation to exhaustion with 100 ml. of ether-chloroform and then with ether, extract the percolates with N/3 hydrochloric acid, nearly neutralise the filtered acid extracts with N/1 sodium hydroxide, add 10 g. of anhydrous sodium carbonate and salt to saturation, and extract with ether; allow the decanted, filtered ether extracts to evaporate spontaneously, dissolve the residue in excess of N/10 sulphuric acid and back titrate with N/10 sodium hydroxide to methyl red.

An official method for the determination of total alkaloids in ephedra is described in *Official Methods of Analysis (A.O.A.C. 1940)*. 10 g. of powdered drug is shaken with 100 ml. of ether-chloroform (3 : 1) and after 5 minutes 5 ml. of 10% ammonia and 0.5 g. of anhydrous sodium carbonate added and shaken occasionally during at least 4 hours. An aliquot part of the clear liquid is extracted with 2% sulphuric acid which is then made ammoniacal, 5 g. of anhydrous sodium carbonate added and completely extracted with ether. The filtered ether extracts are evaporated on a steam-bath with aid of a fan, to a 5 ml. volume, an excess of standard sulphuric acid added, the ether evaporated and back titrated using bromothymol blue indicator. It seems that this process may give low results, due to the volatile nature of ephedra alkaloids when raised above very low temperatures.

The following method is suggested as yielding more consistent results than are obtainable with the B.P.C. method:—10 g. of the herb in No. 40 powder is shaken for 5 minutes with 200 ml. of a mixture of 1 volume of chloroform and 3 volumes of ether. Subsequently 10 ml. of 10% solution of ammonia and 1 g. of anhydrous sodium carbonate are added, the mixture shaken half-hourly for four hours, and then allowed to stand overnight. Next morning the mixture is transferred to a percolator and percolation continued with 100 ml. of the ether-chloroform mixture and then with ether until the alkaloid is completely extracted. The combined percolates are shaken with successive quantities of 40, 30, 20 and 20 ml. of N/3 hydrochloric acid and N/1 sodium hydroxide is added to the combined filtered acid extracts until nearly neutral. 10 g. of anhydrous sodium carbonate is added and sufficient sodium chloride to saturate the solution. The alkaline liquid is extracted with 20, 10, 10 ml. of chloroform followed by successive 5 ml. portions until the alkaloid is completely extracted. Three extractions are usually sufficient. The combined chloroform solutions are washed with 5 ml. of brine, the brine being washed with 5 ml. of chloroform which is added to the main bulk; 20 ml. of N/10 hydrochloric acid is pipetted into the bulked chloroform in a separator, shaken, and the chloroform run into a second separator, where it is washed with distilled water twice, the washings being added to the acid liquors in the separator. The combined acid liquors are titrated with N/10 sodium hydroxide to methyl red.—F. E. Rymill and C. A. Macdonald, *Quart. J. Pharm.*, 1937.

Ephedrina (B.P. Add. IV). $(C_{10}H_{15}NO)_2 \cdot H_2O = 348.3$. Contains 94 to 95% of the anhydrous base, determined by conversion to the hydrochloride and drying at 100°; the product has

a m.p. of 217° to 219° and α_D of the 5% w/v solution in water, -33° to -35° . M.p., without previous drying, 40° to 41° . Ash, not more than 0.1%. Ephedrina Anhydrosa (*B.P.C. Supp. III*), $C_{10}H_{15}NO = 165.1$, is assayed by the same process and contains not less than 98% of pure alkaloid. M.p., 33° to 37.5° , α_D of the hydrochloride obtained in the assay, -33° to -35° . Ephedrina, *U.S.P. XII*, is the synthetic or natural product and may be anhydrous or hydrated. The anhydrous substance contains not less than 98.5% of $C_{10}H_{15}NO$ and the hydrated substance not less than 94% $C_{10}H_{15}NO$. M.p., 34° to 40° , variation being due to differences in moisture content. α_D at 25° of the previously prepared hydrochloride -33° to -35.5° in 5% aqueous solution. Assayed by titration of the substance, dissolved in neutralised alcohol, against N/10 hydrochloric acid, using methyl red indicator. The label on the container must state whether Ephedrine *U.S.P. XII* is anhydrous or hydrated, and when the quantity of alkaloid in a preparation is stated, it is understood to be in terms of anhydrous ephedrine, unless otherwise stated.

Ephedrinæ Hydrochloridum (*B.P. Add. IV*). $C_{10}H_{15}ON, HCl = 201.6$. M.p., 217° to 219° . Specific rotation in 5% w/v aqueous solution, -33° to -36° . Loss at 100° , not more than 0.5%, and ash, not more than 0.1%. The salt of the *U.S.P. XII* is the natural or synthetically produced substance. After drying over sulphuric acid for 24 hours, contains 80 to 82.5% of anhydrous $C_{10}H_{15}ON$. Determined by extraction with successive portions of ether from a solution in saturated brine made alkaline with N sodium hydroxide. The combined ether extracts are washed with brine and then extracted with N/10 sulphuric acid and water. Excess acid is titrated with N/50 sodium hydroxide, using methyl red indicator. Loss over sulphuric acid for 24 hours not more than 2%. Ephedrinum hydrochloricum, *P. Helv. V*, by titration of the chloride, contains in the dried substance not less than 99.6% of $C_{10}H_{15}ON, HCl$.

Tabellæ Ephedrinæ Hydrochloridi (*N.F. VII*). Contain 91 to 109% of the labelled amount of ephedrine hydrochloride, including all tolerances. Assayed by dissolving in water, making alkaline with N/2 sodium hydroxide, extracting the alkaloid either by continuous extraction or by shaking with ether, finally extracting the washed ether solution with N/10 sulphuric acid and titrating the excess acid with N/50 sodium hydroxide, using methyl red indicator.

Ephedrinæ Sulphas (*B.P.C.*). $(C_{10}H_{15}ON)_2, H_2SO_4 = 428.3$. Specific rotation on a 10% w/v aqueous solution, -30° to -31.6° . Loss at 100° , not more than 0.5%. Ash limit, 0.1%. Ephedrinæ Sulphas, *U.S.P. XII*, dried over sulphuric acid for 18 hours and assayed as the hydrochloride, contains 75.5 to 77.3% of anhydrous ephedrine; a moisture limit of 2% is allowed.

Tabellæ Ephedrinæ Sulphatis (*U.S.P. XII*). Contain 93 to 107% of the labelled amount of $(C_{10}H_{15}NO)_2, H_2SO_4$, including all tolerances. Assayed by macerating a weighed quantity of powdered tablets with water and N/1 sulphuric acid for 2 hours, decanting the liquid through a filter, macerating the residue with a further quantity of water, decanting through the same filter and washing the flask and filter with water. After evaporation to a specified volume, the aqueous extract is saturated with sodium chloride, made alkaline with N/1 sodium hydroxide and extracted with ether. The combined ether

extracts are washed with water and the aqueous washings are extracted with a further quantity of ether which is added to the main ether extract. Most of the ether is removed at not more than 30°, an excess of N/50 sulphuric acid added, and the heating continued to remove the remainder of the ether and dissolve the alkaloid. After cooling, the excess N/50 sulphuric acid is titrated with N/50 sodium hydroxide, using methyl red indicator.

Quantitative methods for the determination of ephedrine in inhalants and tablets are described in *Methods of Analysis (A.O.A.C., 1940, 585)*. The ephedrine extracted with ether from ammoniacal solution is treated with excess standard sulphuric acid and back titrated with standard sodium hydroxide using bromothymol blue indicator and using standard indicator at pH 6.0 for comparison.

A colorimetric method for the determination of ephedrine in hypodermic tablets and injections is described. The alkaloid is extracted from ammoniacal solution with methylene chloride and after the combined extracts have been washed with saturated solution of sodium chloride, they are evaporated to dryness with a small quantity of benzoic acid. The residue is dissolved in water, 10% copper sulphate solution and 20% sodium hydroxide solution are added and the mixture is shaken with cyclohexane and allowed to separate. The tint of the upper layer is then determined under specified conditions and tables correlating the value of the red component to the ephedrine content are given.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 249.

Amphetamina (B.P.C. Supp. III). $C_9H_{13}N = 135.1$. Contains 95% to the equivalent of 100% of $C_9H_{13}N$. B.p., 200° to 203°, with slight decomposition. Sp. gr. at 25°, about 0.931. Residue on volatilisation on a steam-bath for 1 hour, not more than 0.1%. Assayed by titration with N/2 sulphuric acid using methyl red indicator.

Amphetaminæ Sulphas (B.P.C. Supp. III). $(C_9H_{13}N)_2 \cdot H_2SO_4 = 368.3$. Contains 72 to 73.5% of the base. Loss at 100°, not more than 1%. Assayed by extraction of the liberated base with ether, addition of excess N/2 sulphuric acid and after evaporation of the ether, back titration with N/2 sodium hydroxide using methyl red indicator.

The following method was used for the estimation of amphetamine in aqueous solution. The solution which is usually acid is neutralised with sodium hydroxide solution (10%) and 1 ml. added in excess. It is then extracted with successive quantities (25, 15, 10 and 10 ml.) of chloroform. Each chloroform extract is washed with the same quantity (5 to 10 ml.) of water, which is then shaken with a little chloroform. The whole of the chloroform used is combined and washed with another 5 ml. of water. The amphetamine is re-extracted from the chloroform by shaking with four successive portions of 10 ml. of N/2 hydrochloric acid. The acid extracts are evaporated to dryness on a water-bath, the residue dissolved in absolute alcohol, filtered into a tared flask, again evaporated to dryness, dried and weighed. Directions are also given for the estimation of amphetamine in viscera and urine. Tablets of amphetamine sulphate may be assayed by the following method. The crushed tablets are heated with 25 ml. of alcohol (50%) for a few minutes on a water-bath and the mixture filtered, the residue being washed with absolute alcohol. The alcohol is removed from the filtrate, evaporation to dryness being avoided, and the remaining liquid filtered into a separator, the filter being rinsed with acidified water. The filtrate is neutralised with sodium hydroxide solution (10%), 1 ml. in excess added, and the process completed by extraction with chloroform as described above.—E. T. Illing, *Analyst*, 1940, 3.

ERGOTA

Ergota (B.P. Add. VI). Should contain not more than 2% of foreign organic matter and not less than 0.2% of total alkaloids, calculated as ergotoxine, of which not less than 15% consists of

water-soluble alkaloids calculated as ergometrine. In the assay the drug in moderately fine powder is defatted by continuous extraction with light petroleum (b.p. 40° to 50°) and dried below 40° . After the addition of anæsthetic ether and dilute solution of ammonia, the drug is exhausted by continuous extraction with ether for about 5 hours. After filtering, washing the filter with ether and addition of acetone, the ethereal solution is extracted with 20, 10, 10 and 10 ml. of 1% tartaric acid solution. Dissolved solvent is removed from the mixed acid solutions at room temperature under reduced pressure, and the volume adjusted with water. 1 volume of the acid solution is mixed with 2 volumes of dimethylaminobenzaldehyde solution (0.125% in a cooled mixture of 65 ml. of sulphuric acid and 35 ml. of water to which 0.1 ml. of ferric chloride solution is added), the mixed solutions allowed to stand 5 minutes and the total alkaloids determined by matching against the blue-violet colour produced with a standard solution of ergotoxine ethanesulphonate similarly treated.

In the determination of the water-soluble alkaloids, an aliquot of the acid solution from the previous assay is made alkaline with dilute solution of ammonia and extracted with anæsthetic ether. The ethereal solution is washed with faintly ammoniacal water saturated with anæsthetic ether and subsequently extracted with 10, 5, 5 and 5 ml. of 1% tartaric acid solution. The water-insoluble alkaloids are then determined in the manner described above. The percentage of water-soluble alkaloids is calculated as ergometrine by multiplying by 0.538 the difference between the percentages of total alkaloids and water-insoluble alkaloids.

The normal total alkaloidal content of Spanish and Portuguese ergot ranges from about 0.2 to 0.3% and the average is about 0.25%. The proportion of water-soluble alkaloid calculated as ergometrine is about 20% of the total alkaloid but some analysts consider that a determination of water-soluble alkaloid is a very inaccurate measure of the ergometrine content and that the latter may be only 10% of the total alkaloid. Russian ergot is usually an inferior article containing a very small proportion of alkaloid and is unsuitable for official use except as a diluent for making prepared ergot.

Ergota, *U.S.P. XII*, contains not more than 4% of seeds, fruits, or other foreign organic matter, not more than 6% of moisture, and is standardised biologically (see below). *Secale cornutum*, *P.G. VI*, assayed by the process prescribed, contains not less than 0.05% of the water-insoluble alkaloids of ergot.

The use of a colorimeter is not essential. Dilute the solutions about ten times with water and compare the colours in Nessler glasses.—P. A. W. Self, *Pharm. J.*, i/1933, 245.

New alkaloids reported are ergocristine, isomeric with ergotoxine, and ergocristinine.—A. Stoll and E. Burckhardt, per *Analyst*, 1938, 54.

The effect of hot solvents on original ergot has been investigated. Ether, dichlorethylene, trichlorethylene and benzene have been found to extract the major portion of the alkaloids; light petroleum does not extract the alkaloids.

In the case of dichlorethylene and benzene, quantitative recovery of the alkaloids has been made, proving that the alkaloids are extracted and not destroyed by the solvents.—R. F. Corran and F. E. Rymill, *Quart. J. Pharm.*, 1935, 337.

60 mg. of water-soluble and 2 g. of water-insoluble alkaloids found per kg. of ergot as compared with the finding of Hampshire and Page that the water-soluble alkaloids amount to $\frac{1}{3}$ th and $\frac{1}{4}$ rd of the water-insoluble alkaloids.—E. Rothlin, *Arch. exp. Path. Pharmac.*, 1937, 184, 69.

Determination of Fat. Widely different results can be obtained in using light petroleum, according to the method applied. The *B.P.* test is unsatisfactory and should be made quantitative; the *B.P.C.* figure of 15 to 30% of fat is an under-estimate and 30 to 40% is closer to the true amount present.—W. A. N. Markwell, *Pharm. J.*, i/1941, 32.

BIOLOGICAL METHODS OF ASSAY

There is no specific biological method of estimating ergometrine which is now recognised as probably the most important alkaloid for clinical purposes.

U.S.P. XII Method. Ergot is assayed by the cock's comb method. When an extract of ergot is injected into the breast muscles of a cock, the ergotoxine present causes a darkening of the colour of the comb. The darkening is first seen in the hindmost part of the comb, and, according to the amount of ergotoxine, spreads forward. An unknown sample of fluidextract is compared with a 0.05% solution of ergotoxine ethanesulphonate in 1% tartaric acid solution. From 5 to 10 cocks of about 2 kg. weight are used for the comparison, and receive doses varying from 0.25 ml. to 0.5 ml. The combs of birds which have been injected with the sample are then compared with those injected with the standard.

Ergot is required to possess a potency per gramme equivalent to not less than 0.5 mg. of the official standard ergotoxine ethanesulphonate.

Rabbit Uterus Method. A method which has been widely used for estimating the ergotoxine present in ergot extracts was described by Broom and Clark (*J. Pharmacol.*, 1923, 22, 59). When strips of the uterus of a rabbit are suspended in a bath of oxygenated Ringer's solution at 37°, the strips contract when adrenaline is added to the bath. If ergotoxine is added to the bath, the power of the strip to respond to adrenaline soon disappears, according to the concentration of ergotoxine and the time it is allowed to act. To estimate the ergotoxine present in an extract, two strips are cut from the same piece of uterine muscle and suspended in baths placed side by side. The response to a given dose of adrenaline is recorded for each strip, and when fresh Ringer's solution has been placed in each bath a dose of ergotoxine is added to one bath and a dose of the unknown extract is added to the other. After an interval which must be the same for each bath, and may be 8 or 10 minutes, the dose of adrenaline is added again. The response is now reduced, and is reduced by the greatest amount in that bath in which most ergotoxine is present. By making observations on many pairs of strips, a figure can be obtained for the amount of ergotoxine in the extract, but the method is tedious and is subject to a large error.

A biological method for the assay of ergot is described in *Methods of Analysis (A.O.A.C., 1940, 627)*.

Ergota Præparata (B.P. Add. VI). Contains from 0.19 to 0.21% of total alkaloids of ergot, calculated as ergotoxine of which not less than 15% consists of water soluble alkaloids,

calculated as ergometrine. Yields on extraction with light petroleum (b.p., 40° to 50°), not more than 5% of fat.

Extractum Ergotæ (B.P.C.). When freshly prepared, contains 0.5% of total alkaloids, calculated as ergotoxine. *Extractum Ergotæ, N.F. VII*, when assayed by the *U.S.P. XII* method, has a potency per g. equivalent to 1.6 mg. of ergotoxine ethanesulphonate reference standard.

Extractum Ergotæ Liquidum (B.P.). Assayed by extracting the diluted extract, made ammoniacal, with anæsthetic ether, shaking the ether with tartaric acid solution and proceeding as for the assay of Ergota, it contains when freshly prepared 0.06% *w/v* of total alkaloids, calculated as ergotoxine; after storage it contains not less than 0.04% *w/v*. *Fluidextractum Ergotæ, U.S.P. XII*, is of the same strength as the *U.S.P. XI* preparation, 1000 ml. being obtained from 1000 g. of recently ground drug, but no assay process is prescribed.

The colour with *p*-dimethylaminobenzaldehyde is given also by the pharmacologically inactive alkaloids ergotinine and ψ -ergotinine which are present in liquid extract of ergot. About 60 to 70% of the total alkaloids consists of ergotoxine and the standard of 0.05% of total alkaloids corresponds therefore to about 0.03% of ergotoxine.—*Rep. of Pharmacopœia Sub-Committee on Ergot, October, 1931.*

Stability. When diluted in a mixture it will lose all activity in 2 or 3 days, but if stored in completely filled unopened bottles the loss of activity during six months is inappreciable.—B. A. Bull, *Pharm. J.*, i/1933, 317.

If the liquid extract is kept under ordinary dispensary conditions for more than six weeks the strength is likely to fall below the *B.P.* limit. The keeping properties are much improved by storage in full bottles in the dark, and the deterioration in an ice-chest is very slow.—E. M. Smelt, *Quart. J. Pharm.*, 1933, 399.

On dilution with water, it yields a precipitate which contains the greater part of the alkaloids. The loss in strength is about 30% in 10 to 14 days. When dispensed with other substances the rate of loss of activity differs with different extracts but is usually more rapid. Ferric chloride greatly increases the loss of activity.—E. F. Hersant and W. H. Linnell, *Pharm. J.*, ii/1933, 3.

Ergometrina (B.P. Add. I). $C_{19}H_{23}O_2N_3 = 325.2$. M.p. of the lower melting form, on the air-dried substance and raising the temperature 4° per minute, 162° to 164°, with decomposition; m.p. of the higher melting form, on material dried *in vacuo* for one hour at 140°, 212° with decomposition. α_D of 1.5% *w/v* solution in dehydrated alcohol, using the air-dried substance and calculated on the substance with the associated solvent removed, +40° to +43° (sodium light), and +60° to +63° (mercury light). Associated solvent determined by heating *in vacuo* for one hour at 140°.

Ergonovinæ Maleas (U.S.P. XII). $C_{19}H_{23}N_3O_2 \cdot C_4H_4O_4 = 441.5$. Loses not more than 2% when dried over sulphuric acid and then contains 98% of $C_{19}H_{23}N_3O_2 \cdot C_4H_4O_4$. M.p., with decomposition, about 167°; α_D at 25° determined on an aqueous solution containing 1% of dried material, +48° to +57°. Assayed by extraction with ether from an ammoniacal alcohol solution, previously diluted with saturated brine, removal of the ether, addition of excess N/50 hydrochloric acid and back titration with N/50 sodium hydroxide, using bromophenol blue indicator.

Tabellæ Ergonovinæ Maleatis (U.S.P. XII). Contain 90 to 110% of the labelled amount of $C_{12}H_{13}N_3O_2 \cdot C_4H_4O_4$, including all tolerances. Assayed by maceration of a weighed quantity of powdered tablets with alcohol, filtering and colorimetric estimation using dimethylaminobenzaldehyde in an aliquot of the filtrate.

Determination of Ergometrine. Ergometrine differs from ergotamine and ergotinine by being moderately soluble in water whereas the other alkaloids are insoluble. It can be extracted from an ethereal solution of total alkaloids by shaking with water. The colour produced by 0.538 g. of ergometrine in the dimethylaminobenzaldehyde test (using Allport and Cocking's reagent) is equivalent to that produced by 1 g. of ergotamine base. In the following assay the total alkaloids and the water-insoluble alkaloids, both expressed as ergotamine, are determined; the difference gives the water-soluble alkaloids as ergotamine, and the latter figure multiplied by 0.538 gives the equivalent of ergometrine. **Total alkaloids.**—Shake 60 ml. of the ethereal solution with successive quantities of 10, 10, 5, and 5 ml. of a 1% w/v solution of tartaric acid. Mix the acid solutions and warm gently in a current of air. Cool and dilute to 30 ml. with water. Mix 1 ml. with 2 ml. of solution of dimethylaminobenzaldehyde and allow to stand for five minutes. Mix 1 ml. of solution of ergotamine ethanesulphonate with 2 ml. of solution of dimethylaminobenzaldehyde and allow to stand for five minutes. Determine the ratio of the colour intensities by comparing them in a suitable colorimeter. **Water-insoluble alkaloids.**—Shake the remaining 60 ml. of ethereal solution with successive quantities of 20 ml. of water made faintly alkaline to litmus with ammonia, until 1 ml. of the separated aqueous liquid gives no blue colour when mixed with 2 ml. of solution of dimethylaminobenzaldehyde. Shake the ethereal solution with successive quantities of 10, 10, 5, and 5 ml. of a 1% w/v solution of tartaric acid. Mix the acid solutions and remove the ether by gentle warming in a current of air. Cool, dilute to 30 ml. with water, and compare with solution of ergotamine ethanesulphonate as described in the assay for total alkaloids. The difference between the results of these two assays multiplied by 0.538 gives the water-soluble alkaloids calculated as ergometrine. The figure includes also any ergometrinine.—C. H. Hampshire and G. R. Page *Quart. J. Pharm.*, 1936, 60.

A colorimetric method for the determination of ergometrine and ergotamine in hypodermic tablets and injections.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 246.

Assay of Ergotocin (Ergometrine). A comparison of six different methods of assay—polarimetric, colorimetric, cock's comb, isolated rabbit's uterus, post-partum dog's uterus and post-partum human uterus. The isolated rabbit's uterus method, preferably supplemented by the clinical method, is preferred. The oxytocic action typifies ergotocin and eliminates ergotamine and ergotamine, and the prolonged rhythmic contractions distinguish it from histamine and tyramine which give only brief responses. The post-partum dog's uterus is less sensitive than the human. The Broom and Clark method is inapplicable since ergotocin has no inhibitory action on adrenaline and its own action on the isolated rabbit uterus is diminished by the previous application of ergotamine or ergotamine.—E. E. Swanson *et al.*, *J. Amer. pharm. Ass.*, 1935, 836.

Precipitation with picric acid can be used for demonstrating the alkaloids of the ergotamine group in ergometrine. Ergometrine can be assayed by titration with hydrochloric acid using bromophenol blue as indicator.—F. Reiners, *Quart. J. Pharm.*, 1938, 253.

Assay of Ergot and its Liquid Extract for Ergometrine.

The method previously described by Hampshire and Page for the separate determinations of the water-soluble and the water-insoluble alkaloids of ergot has been modified and applied to the liquid extract.

ASSAY OF LIQUID EXTRACT.

(a) **Total Alkaloids.** 25 ml. of liquid extract in a Watkins extractor is made alkaline with ammonia and extracted with pure ether for six hours. Transfer the aqueous-ether liquid to a separator and shake out with 4 × 5 ml. of 1% tartaric acid. Warm the mixed acid liquids, dilute to 25 ml. and determine colorimetrically with standard ergotamine ethanesulphonate solution.

(b) **Water-insoluble Alkaloids.** 25 ml. of liquid extract made alkaline to litmus with ammonia is extracted with 3 × 40 ml. of pure ether. Shake the mixed ethereal solutions with 5 × 40 ml. of water previously made alkaline with ammonia and saturated with pure ether. Extract the washed ether solution

with 4 × 5 ml. of 1% tartaric acid, remove ether by warming, dilute to 25 ml. and compare with the ergotoxine solution as before.

(c) *Water-soluble Alkaloids*. This is determined by difference and expressed as ergometrine by multiplying by the factor 0.538.

ASSAY OF ERGOT. Extract 10 g. in moderately fine powder with light petroleum (40° to 50°) in a continuous extractor to remove fat and dry the residue below 40°. Mix in a dish with pure ether to form a soft paste and stir with 2 ml. of strong ammonia. Replace the residue in the extractor and extract for 5 hours with 100 ml. of pure ether. Filter and wash the filter and flask with pure ether until 120 ml. is obtained. Shake the ethereal solution with 20, 10, 10 and 10 ml. of 1% tartaric acid, warm to remove ether, cool and dilute with water to 50 ml.

For *total alkaloids* mix 2 ml. of dimethylaminobenzaldehyde reagent with 1 ml. of the alkaloidal solution and determine colorimetrically against standard ergotoxine ethanesulphonate solution. For *water-insoluble alkaloids* take 25 ml. of the alkaloidal solution, make alkaline with ammonia and extract with 40, 30, 30 and 20 ml. of pure ether. Then shake the ether with 5 × 40 ml. of alkaline water saturated with ether and extract this washed ethereal solution with 10, 5, 5 and 5 ml. of 1% tartaric acid. Warm the mixed acid solutions to remove ether, cool, dilute to 25 ml. with water and determine colorimetrically as before.—C. H. Hampshire and G. R. Page, *Quart. J. Pharm.*, 1938, 57.

The determination devised by Hampshire and Page for powdered ergot is extended for the liquid extract and tablets.—C. K. Plycart, *J. Ass. off. agric. Chem.*, 1937, 28, 566.

While methods are available for the separation of water-soluble ergot alkaloids from water-insoluble, there is none for the separation of ergometrine from its inactive isomer, ergometrinine. The following method is therefore presented:—25 ml. of a solution of the alkaloids in 1% tartaric acid solution is made faintly alkaline to litmus with ammonia, 35 ml. of ether (U.S.P.) added and the mixture shaken for 3 minutes. The aqueous layer is washed with two 35-ml. portions of ether contained in two other separating funnels, and finally run into a 250-ml. beaker. The process is repeated with six 10 ml. portions of water containing sufficient ammonia to give it a pH of 10, and the aqueous extracts combined in the beaker. The combined extract is warmed slightly to remove any dissolved ether, the volume adjusted to 100 ml. and then assayed colorimetrically. By this method, about 98 to 99% of the ergometrine is obtained together with about 5% of ergometrinine, the ergometrine giving slightly high results. By applying the method to a mixture of water-insoluble alkaloids only, it was found that the second ether wash contained 5.7% of the total alkaloids used, and the third ether only 0.2%. This indicates that, in the Hampshire-Page assay process, about 6% of the water-insoluble alkaloids may be present in the aqueous extract.—D. C. Grove, *J. Amer. pharm. Ass., Sci. Edn.*, i/1941, 260.

A new method for the separation of ergometrine from other alkaloids in ergot and the liquid extract has been worked out by Allport and Porter in which a solution of the mixed alkaloids in chloroform containing 1.0% v/v of ethyl alcohol is added to a 2% solution of antimony trichloride in chloroform.

ASSAY OF LIQUID EXTRACT. To 10 ml. in a separator add 1 ml. of 10% ammonia and 25 ml. of methylene chloride, shake, separate the lower layer and repeat the extraction 6 times with 25 ml. of methylene chloride or until extraction is complete. Distill off the solvent, dry the residue by two evaporations with 5 ml. of acetone, dissolve in 25 ml. of special chloroform containing 1.0% v/v of ethyl alcohol and filter through cotton wool into a beaker containing 25 ml. of the special chloroform with 5 ml. of 2% w/v antimony trichloride in chloroform, stir, wash the flask, etc., with a further 20 ml. of the special chloroform, allow to stand one hour, and collect the precipitate in an ignited asbestos Gooch crucible, washing the beaker and precipitate with 20 ml. of a 0.2% w/v antimony trichloride solution in the special chloroform. Triturate the contents of the crucible in a beaker with 2 ml. of 95% alcohol, add 30 ml. of 15% tartaric acid solution warmed to 40°, allow to stand $\frac{1}{2}$ hour and dilute the solution with the asbestos to 50 ml. Take 1 ml. of the liquid and determine the ergometrine colorimetrically with 2 ml. of *p*-dimethylaminobenzaldehyde reagent in a Lovibond tintometer or against standard ergotoxine solution.

ASSAY OF ERGOT. Remove the fat from 10 g. in No. 60 powder by percolation with cold light petroleum (40° to 50°) and dry below 40°. Mix slowly in a mortar with 7.5 ml. of strong solution of lead subacetate, triturate for five

minutes and percolate with 250 ml. of a mixture of 9 volumes of pure ether and 1 vol. of methylene chloride until 2 ml. of the percolate gives no blue colour in the *p*-dimethylaminobenzaldehyde reaction. Evaporate the percolate to dryness, dry the residue with acetone and proceed as described in the process for the liquid extract.

Results given range from 0.003% in Russian ergot to 0.180% in a sample of ergot of *Festuca* grass, and from 0.004% in a liquid extract made by the B.P. 1914 process from Russian ergot to 0.036% in a liquid extract made by the B.P. 1932 process from an ergot giving 0.06% of alkaloid by the B.P. assay.—N. L. Allport and G. V. Porter, *Quart. J. Pharm.*, 1938, 96.

The methods of the B.P. '32, of Hampshire and Page and of Allport and Porter are examined and criticised and a new method using acetone as solvent is described.—C. Daglish and F. Wokes, *Quart. J. Pharm.*, 1939, 451.

The Hampshire-Page method of assay requires eight hours' extraction in a Soxhlet apparatus to ensure complete extraction, whereas the acetone-ammonia method of Wokes and Daglish is quicker and gives a higher yield of alkaloids.—S. A. Schou and M. Tønnesen, *Dansk Tidsskr. Farm.*, 1940, 14, 33.

Neither continuous extraction of ergot with methylene chloride nor shaking ergot with a menstruum of ammoniacal acetone completely extracts the alkaloids, whereas continuous extraction with anæsthetic ether for four to five hours does give complete extraction. During the last process, about 2% of the alkaloids are decomposed.—C. H. Hampshire and M. W. Partridge, *Quart. J. Pharm.*, 1941, 116.

In the Hampshire and Partridge ether-extraction process, it appeared that about 97% of the alkaloids were extracted in the first hour. It would be advisable to remove the ether after that time and continue the extraction with a fresh supply, to avoid a large amount of decomposition due to heating the alkaloids for five hours.—W. H. Linnell, *Quart. J. Pharm.*, 1941, 177.

The experimental error of the colour matching in ergot assays is a serious obstacle to further advance. The lowest estimate of the experimental error when using the colorimeter is 2%.—F. Wokes, *Quart. J. Pharm.*, 1941, 178.

A rapid method for the assay of ergometrine and ergotoxine is described. The total alkaloids are extracted by maceration and suction percolation with ammoniacal acetone, followed by a similar treatment with a mixture of ether and an aqueous suspension of magnesium oxide. After transference of the total alkaloids to an aqueous solution of tartaric acid, the ergotoxine is separated by extraction with ether after adjusting the reaction of the aqueous solution to pH 5.5. The ergometrine which remains in the aqueous layer is transformed to a solution of smaller volume and both alkaloids are finally determined colorimetrically. The method has also been applied to liquid extract of ergot.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1941, 106.

Methods of assay are described in which the ergotoxine and ergometrine groups of alkaloids are separated and determined.—S. A. Schou, M. Tønnesen and I. Bennekou, per *Quart. J. Pharm.*, 1939, 119.

An assay process is described for ergot and liquid extract of ergot in which ergometrine is completely separated from ergotoxine-like alkaloids.—E. E. Swanson *et al.*, *J. Amer. pharm. Ass., Sci. Edn.*, 1941, 255.

Ergometrine may be prepared by the following process:—1 kg. of defatted powdered ergot is moistened with 1.5 litres of absolute methylated alcohol (5% methyl alcohol) to which 50 ml. of 0.88 ammonia has been added. The wet material is extracted in a percolator with absolute methylated alcohol. After about 3 litres of percolate have been collected, the extract is evaporated to about 200 ml. in a vacuum, the water-bath temperature being kept at 40° to 45°.

To this concentrate are added about 300 ml. of 0.25 N sulphuric acid (sufficient to render the reaction faintly acid to congo-red), and the distillation is continued until all the residual alcohol has been removed. Fat separates as the content of alcohol decreases. The fluid is then chilled at about 2°, when most of the fat becomes hard enough to be removed mechanically.

After filtration through paper, the acid aqueous solution, measuring 200 to 250 ml., is treated with saturated aqueous sodium carbonate solution (about 10 ml.) until the reaction is very faintly alkaline to litmus. It is then filtered from the flocculent precipitate which is produced, made alkaline by the addition of more saturated sodium carbonate solution (about 20 ml.) and extracted five times with 50 ml. quantities of chloroform. The chloroform extract is freed from watery droplets, carried over mechanically, by shaking with a small quantity of

anhydrous sodium carbonate, filtered, and evaporated in a vacuum (water-bath at 45° to 50°). As the solution is concentrated, crude crystalline ergometrine separates. The volume is reduced to from 5 to 10 ml. After keeping at 2° for an hour the crude ergometrine is collected on a filter and washed with a little chloroform. Suitable solvents for the recrystallisation of ergometrine are benzene, acetone, ethyl acetate, and methylethyl ketone; after adequate recrystallisation, e.g., from methylethyl ketone, it melts and decomposes at 161° to 162°. The yield from defatted Spanish ergot was 0.2 g. per kg.—H. W. Dudley, *Pharm. J.*, i/1935, 709.

The purest specimen of ergometrine obtained, exhibiting an E value of 185 and melting at 164°, gave a colour by the chemical test equivalent to that produced by 1.78 times its weight of ergotoxine base. Ergometrine in aqueous tartaric acid solution shows an absorption band in the ultra-violet region with a maximum at 316 m μ . The same band is exhibited by solutions of ergotoxine. The colour produced when ergometrine is submitted to the *p*-dimethylamino-benzaldehyde test is spectroscopically identical with that produced by ergotoxine under the same conditions.—N. L. Allport and Sydney K. Crews, *Quart. J. Pharm.*, 1935, 447.

Ergotoxina (B.P.C.). Specific rotation, determined on a 2% *w/v* solution of the anhydrous substance in chloroform, not less than -180°. On drying *in vacuo* at 90° it loses not more than 5%. At 190° to 200° the dry substance decomposes with evolution of gas. Ash limit, 0.1%.

Ergotoxinæ Ethanosphonas (B.P. Add. I). Specific rotation, determined on a 4% *w/v* solution of the anhydrous substance in acetone and water (2:1 by volume), +119° to +122°, and of the separated anhydrous base, the same as specified for Ergotoxina. The anhydrous salt contains acid equivalent to 16 to 16.7% of ethanesulphonic acid. Loses *in vacuo* at 90° to 100° not more than 5%. Ash limit, 0.1%.

Ergotamine. Ergotamine is less active biologically than ergotoxine but is approximately equivalent when examined colorimetrically. If used as a standard in the biological assay of ergot, 60% of the observed readings gives a close approximation of the ergotoxine content. A similar correction should be applied in the colorimetric assay of ergot owing to the biological inactivity of ergotinine.—E. Lozinski, G. W. Holden and G. R. Driver, *Quart. J. Pharm.*, 1933, 395.

Ergotinine is included in the *Fr. Cx.* 1937.

Ergotaminæ Tartras (U.S.P. XII). α_D at 25° of 0.4% solution in chloroform, -125° to -155°. Darkens on heating at 177° and decomposes at 184°. A test for foreign substances is included.

Tabellæ Ergotaminæ Tartratis (U.S.P. XII). Contain 90 to 110% of the labelled amount of $(C_{33}H_{35}N_5O_6)_2 \cdot H_2C_4H_4O_6$, including all tolerances. In the assay, a weighed quantity of powdered tablets is first extracted twice with light petroleum and the light petroleum rejected. The residue is then extracted 4 times with chloroform saturated with ammonia, each chloroform extract being passed through a filter and, finally, the residue is transferred to the filter and washed with chloroform. The combined chloroform extracts are washed with water and the aqueous washings are extracted with a further quantity of chloroform. After removal of almost all the chloroform, the alkaloidal residue is evaporated with alcohol and finally dried *in vacuo* over sulphuric acid and weighed.

Histaminæ Phosphas Acidus (B.P. Add. I). $C_5H_9N_3 \cdot 2H_3PO_4$ = 307.2. M.p., 130° to 133°, after sintering at 127°. Loss in a vacuum desiccator, not more than 1%. Histaminæ Phosphas, U.S.P. XII, dried at 100°, loses not more than 1.5%; m.p. about 130°.

EXTRACTUM FELLIS BOVINI

Extractum Fellis Bovini (B.P.). Gives no precipitate on addition of 2 vols. of alcohol (90%) to 1 vol. of a 1% *w/v* aqueous solution.

Tabellæ Extracti Fellis Bovis (U.S.P. XII). Contain an amount of the extract corresponding, in content of bile acids determined as cholic acid, to not less than 40% of the labelled amount of extract, including all tolerances. Assayed by triturating a weighed quantity of powdered tablets with alcohol (80%), passing the alcohol through a filter and making the solution up to volume. The bile acids are determined by diluting the solution, removing the alcohol from 1 ml. of the dilution *in vacuo* at room temperature, and adding water, 1% aqueous solution of furfural, sulphuric acid-water mixture (10 : 13), and heating at 70° for 8 minutes followed by immersion in ice-water for 2 minutes. The blue colour produced is compared with a standard solution of U.S.P. cholic acid reference standard similarly treated.

Sodii Tauroglycocholas (B.P.C. Supp. IV). When prepared from ox bile consists of a mixture of $C_{26}H_{44}O_7NSNa$ and $C_{26}H_{42}O_6NNa$ with small proportions of sodium taurodeoxycholate and sodium glycodeoxycholate. When prepared from pig bile contains compounds of taurine and glycine with hyodeoxycholic acid. Yields not less than 70% of total bile acids. Acid value of total bile acids from the assay, not greater than 145. Sulphated ash, 13 to 17%. Assayed by hydrolysis by refluxing with 15% sodium hydroxide solution for 12 hours, dilution and extraction of the filtered liquid and washings with ether, evaporation and drying at 100°.

FERRUM

Ferri Carbonas Saccharatus (B.P.). Assayed for ferrous iron content by titration of a phosphoric acid solution, diluted with warm water and 25% *w/v* sulphuric acid, with N/10 potassium dichromate using diphenylamine as indicator. Ferrous iron content, as $FeCO_3$, not less than 50%. The N.F. VII preparation is made with lactose and sucrose instead of glucose; it is assayed by titration against N/10 ceric sulphate using ortho-phenanthroline as indicator, and contains not less than 15% of $FeCO_3$. Ferrum Carbonicum cum Saccharo, P.G. VI, contains from 9.5 to 10% of iron. Ferrum oxydatum cum Saccharo, P.G. VI, contains from 2.8 to 3% of iron.

The iodate method is suitable for the assay of the saccharated iron compounds of the B.P. and B.P.C. and of ferrous lactate. Ferrous iron may be titrated with accuracy by iodate in the presence of liquid glucose, acacia, tragacanth, sucrose, invert sugar in small amounts, lævulose, dextrose, lactose, glycerin, lactic acid and citric acid. Invert sugar in great excess produces a small error. The method is unsatisfactory in the presence of liquorice, marsh-mallow, quinine and aqueous extract of cochineal.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1935, 344.

Assay. The following method, using ceric sulphate, gives more accurate results than the official method. Digest about 2 g. accurately weighed, with 8 ml. of cold 25% *w/v* sulphuric acid until the mass has disintegrated. Dilute with 20 ml. of water and titrate with N/10 ceric sulphate using phenylanthranilic acid as internal indicator. Phenylanthranilic acid may be prepared by heating for an hour under a reflux condenser a mixture of bromobenzene 3.5 g., anthranilic

acid 3 g., anhydrous potassium carbonate 3 g., cuprous chloride 0.1 g., and nitrobenzene 15 g. The product is steam-distilled to remove the nitrobenzene and the crude acid precipitated by acidifying the hot liquid with dilute hydrochloric acid. The acid is dissolved with sodium hydroxide, the solution filtered and again precipitated with hydrochloric acid, and the crystals purified by reprecipitation and recrystallisation from alcohol. The indicator solution is prepared by dissolving 0.11 g. of phenylanthranilic acid and 0.3 g. of anhydrous sodium carbonate in 100 ml. of water. It becomes faintly pink on long standing but remains satisfactory as an indicator.—C. G. Lyons and F. N. Appleyard, *Quart. J. Pharm.*, 1937, 343.

Pilula Ferri Carbonatis (B.P.). Contains not less than 20% of ferrous iron, calculated as FeCO_3 , determined by digestion with phosphoric acid and water, addition of sulphuric acid and titration with N/10 potassium dichromate, using diphenylamine indicator.

Massa Ferri Carbonatis (U.S.P. XII). Contains 36 to 41% of FeCO_3 ; determined by titration in acid solution with N/10 ceric sulphate, using orthophenanthroline indicator. **Pilulae Ferri Carbonatis, U.S.P. XII,** determined similarly, contains in each pill not less than 0.06 g. of FeCO_3 .

Ferri et Ammonii Citras (B.P.). Contains from 20.5 to 22.5% of Fe. The assay by warming with 30 parts of water and 2 parts of sulphuric acid, oxidising the cooled solution with N/10 potassium permanganate, allowing interaction to proceed for 3 minutes with 30 parts of hydrochloric acid and 4 parts of potassium iodide, and titrating the liberated iodine with N/10 sodium thiosulphate, replaces the B.P. '14 method of weighing the ignited residue. **Ferri et Ammonii Citrates, U.S.P. XII,** should contain from 16.5 to 18.5% of Fe, and is assayed by interaction of a solution with hydrochloric acid and potassium iodide during 15 minutes. The *Fr. Cx.* 1937 substance, by re-ignition with nitric acid, contains 24 to 26% of iron oxide. **Ferrum citricum ammoniatum, P. Helv. V,** is assayed iodometrically and should contain from 17 to 18% of iron.

Ferri et Ammonii Citras Viridis (B.P.C.). Fe content determined as for **Ferri et Ammonii Citras**, from 14 to 16%. **Ferri et Ammonii Citrates Virides, U.S.P. XII,** contains 14.5 to 16% of Fe.

Ferri et Ammonii Citro-Arsenis (B.P.C. Supp. IV). Contains not less than 14% of Fe, and 1.3 to 1.5% of As_2O_3 . Assayed for iron by the process described for **Ferri et Ammonii Citras**, subtracting the volume of N/10 iodine required, for an equal weight, in the assay for arsenic trioxide from the volume of N/10 sodium thiosulphate; and assayed for arsenic trioxide by interaction, in presence of sodium bicarbonate, with excess N/10 iodine during 7 mins. and back titration with N/10 sodium thiosulphate.

Ferri et Mangani Citras (B.P.C.). Assayed by the method for **Ferri et Ammonii Citras**, should contain not less than 14% of Fe, and not less than 7% of Mn by the following process of the B.P.C.: 0.1 g. boiled till a clear solution is produced with 25 ml. of dilute nitric acid, is heated with 12 ml. of N/10 silver nitrate and 1 g. of ammonium persulphate for 30 seconds after oxidation commences; the cooled solution is titrated with N/100

the iodate method of Heisig. Ferrous chloride mixed with soft paraffin and enclosed in glyco-gelatin capsules is best determined by ceric sulphate.—G. J. W. Ferrey, *ibid.*, 351.

The following assay is recommended by the Sub-Committee on Inorganic Chemicals of the Committee on General Chemistry:—Dissolve about 1 g., accurately weighed, in 20 ml. of a 25% *w/v* aqueous solution of sulphuric acid, in a stoppered flask. Add 6 ml. of strong solution of iodine monochloride and 60 ml. of hydrochloric acid; titrate with M/20 potassium iodate until the solution becomes light brown in colour; add 5 ml. of chloroform and continue the titration until the chloroform becomes colourless. Each ml. of M/20 potassium iodate is equivalent to 0.02317 g. of FeCl_2 .—(*British Pharmacopœia Commission Report*, No. 14, September 1939.)

Syrupus Ferri Phosphatis (B.P.C.). By the *B.P.* titanous chloride titration method used for *Syrupus Ferri Phosphatis Compositus*, an iron content equivalent to from 1.7 to 1.9% *w/v* of $\text{Fe}_3(\text{PO}_4)_2$ should be indicated.

Syrupus Ferri Phosphatis Compositus (B.P.). Contains iron equivalent to from 0.85 to 0.95% *w/v* of anhydrous ferrous phosphate, $\text{Fe}_3(\text{PO}_4)_2$, and calcium equivalent to from 1.3 to 1.5% *w/v* of tricalcium phosphate. Assayed for iron by diluting a weighed portion with water, adding a few drops of hydrochloric acid and a 2% potassium permanganate solution until a transient pink colour is produced throughout the solution; after addition of more hydrochloric acid and sodium bicarbonate, N/10 titanous chloride solution is added until the commencement of the titration is indicated by the production of a blue colour on adding one drop of the titration liquid to one drop of potassium ferricyanide solution; the ferric iron is then titrated with N/10 titanous chloride using ammonium thiocyanate solution as indicator. Calcium is determined by well diluting a weighed portion, adding citric acid, and boiling, making just alkaline with ammonia, then adding acetic acid and, to the boiling solution, excess of ammonium oxalate solution; after boiling gently on a sand-bath for 2 hours, the precipitate is collected, washed and ignited with sulphuric acid.

Assay of Syr. Ferri Phosph. Co. The following assay, based on the method of Bradbury and Edwards (*J. Soc. chem. Ind., Lond.*, 1940, 96) is stated to overcome the difficulties of the official method. To about 20 g. of the syrup in a glass-stoppered separating funnel, add 1 ml. of sulphuric acid (50% *w/v*) and sufficient N/10 potassium permanganate to produce a transient pink. Adjust the volume to 40 ml., add 3 ml. of ammonium thiocyanate solution (40% *w/v*), and titrate with mercurous nitrate solution, rotating the funnel gently throughout. When the solution becomes brownish and obscures any red colour, add 20 ml. of ether and shake for thirty seconds. Run off the aqueous layer into a second separator, leaving any precipitated mercury in the first. Shake the contents of the second separator with 15 ml. of ether for thirty seconds; reject the aqueous layer. Add the second ethereal layer to the first, wash the second separator with 50 ml. of water, and add this to the mixed ethereal extracts. Shake the mixture well for twenty seconds to dissolve any mercury, and continue the titration, with shaking after each addition, until the red colour disappears. The mercurous nitrate solution is approximately N/10 in nitric acid (5% *w/v*). To standardise, place 10 ml. of N/10 ferric alum solution, 1 ml. of sulphuric acid (50% *w/v*), 29 ml. of water and 3 ml. of ammonium thiocyanate solution (40%) in a separator and titrate with the mercurous nitrate solution exactly as described in the assay process.—F. R. Bradbury, K. C. Chatterjee and E. G. Edwards, *Quart. J. Pharm.*, 1940, 297.

The pharmacopœial method for titration of iron with titanous chloride, owing to the instability of the reagent and the necessity for storing it in an inert

atmosphere, is inconvenient where only occasional determinations are required. The method described is rapid and convenient and requires little manipulation. Iron in the ferric state can be precipitated quantitatively by means of 8-hydroxyquinoline at pH 5 to 5.3 without interference from the other constituents of compound syrup of ferrous phosphate, Easton's syrup and many other B.P.C. iron syrups and preparations. Oxidation to ferric iron is effected by boiling with a definite amount of nitric acid and solution of ammonium citrate is added to act as a buffer and keep the calcium in solution. The most suitable temperature for precipitation of iron is 80° to 90°. Manganese and magnesium in the presence of iron may also be determined by this method. *Method*.—Accurately weigh 10 to 15 ml. of syrup of ferrous phosphate and heat to boiling with an equal weight of water and 2.0 ml. of nitric acid. Add 200 ml. of water and 20 to 30 ml. of solution of ammonium citrate solution (B.P. lead test solution). Heat to 80° to 90° and add 10 ml. of a 5% alcoholic solution of oxine. Stir, allow to stand for 2 to 3 minutes, filter through a tared sintered glass crucible, wash well with hot water and dry at 100° for 1 hour. 1 g. of precipitate = 0.1145 g. of Fe or 0.2444 g. of $\text{Fe}_2(\text{PO}_4)_3$. Alternatively, where small amounts of precipitate are concerned, it may be advantageous to use a volumetric method of estimation. The iron-oxine complex, containing 0.01 g. to 0.015 g. of Fe, is filtered and washed in the usual manner and is then dissolved on the filter in 20 ml. of hot hydrochloric acid-water mixture (1 : 1). The solution is sucked through into a stoppered bottle and the crucible washed with cold water, the total volume in the bottle being made up to about 130 ml. Excess N/10 bromide-bromate is added and the mixture allowed to stand for 5 minutes. 20 ml. of phosphoric acid is added to prevent the liberation of iodine from potassium iodide by the ferric iron present. Finally, 1 g. of potassium iodide is added and the liberated iodine titrated immediately with N/10 sodium thiosulphate. 1 ml. N/10 bromine = 0.000465 g. of Fe.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1942, 255.

Assay for Calcium. The following method is much quicker and less troublesome than the pharmacopoeial determination, and the results obtained are in good agreement. Calcium is most completely precipitated as oxalate from a solution at pH 4.4 to 4.6 (green to blue-green with bromocresol green). The calcium solution is brought to this pH by taking 10 to 20 ml. of the sample, adding an equal volume of water and 4 ml. of nitric acid, boiling to oxidise iron and destroy colouring matter, then adding 20 ml. of ammonium citrate solution and diluting to 150 ml. The solution is then boiled, tested with bromocresol green, and treated with 50 ml. of ammonium oxalate solution, boiled gently for 15 minutes and filtered hot by suction through a tared sintered glass crucible. The precipitate is then thoroughly washed with cold water, dried at 100° for about 1 hour and weighed as $\text{Ca}(\text{COO})_2 \cdot \text{H}_2\text{O}$.—G. J. W. Ferrey, *ibid.*, 1942, 264.

Syrupus Ferri Phosphatis cum Quinina et Strychnina (B.P.). Should contain iron equivalent to from 1.62 to 1.98% w/v of $\text{Fe}_2(\text{PO}_4)_3$, 1.04 to 1.2% w/v of anhydrous quinine, and 0.022 to 0.027% w/v of strychnine. Assayed for iron by the titanous chloride titration method; for quinine, by adding sodium citrate to a dilution of the syrup and sodium hydroxide solution and extracting with chloroform; from the weight of the dried residue of total alkaloid the weight of strychnine is subtracted; the residue of total alkaloid is then dissolved in N/1 hydrochloric acid and an equal volume of saturated sodium chloride solution and extracted five times with 5-minute shakings with chloroform; the chloroform liquids are shaken with water and ammonia solution, evaporated, alcohol added, evaporated and dried at 100°; the residue is then washed with three 2 ml. portions of (2 : 1) ether and light petroleum (b.p., 50° to 60°) saturated with strychnine, evaporated with alcohol and, after drying at 100°, the residue of strychnine is weighed. The B.P. Add. VI includes **Syrupus Ferri Phosphatis cum Strychnina** which complies with the

above standards with the omission of quinine, and which is to be supplied when Easton's syrup is ordered.

Determination of Iron in Easton's Syrup. The disadvantages of the official method are overcome by applying the method of Bradbury and Edwards (*J. Soc. chem. Ind., Lond.*, 1940, 96) for the direct titration of iron with mercurous nitrate in the presence of thiocyanate ions. The method is as follows:—To about 12 g. of sample add 1 ml. of sulphuric acid (50% w/v), followed by N/10 potassium permanganate drop by drop until a transient pink colour is produced throughout the solution. Adjust the volume to 40 ml., add 10 ml. of ammonium thiocyanate solution (40% w/v) and titrate with mercurous nitrate solution in a glass-stoppered bottle, which is rotated throughout. Near the end-point a black precipitate is coagulated by shaking with 10 ml. of chloroform, and the titration then continued until the red colour just disappears. The mercurous nitrate solution is approximately N/10 in 5% w/v nitric acid. It is standardised by means of N/10 ferric ammonium sulphate, using a 40% w/v solution of ammonium thiocyanate.—F. R. Bradbury, K. C. Chatterjee and E. G. Edwards, *Quart. J. Pharm.*, 1940, 297.

Hydrogen peroxide is a more satisfactory oxidant for iron than potassium permanganate in the thiocyanate determination. The red colour can be made stable for several minutes, depending on the amount of peroxide used, and the faded colour may be restored if necessary by the addition of more peroxide. Too much peroxide may cause a yellowish interfering colour due to oxidation products of thiocyanate.—C. A. Peters *et al.*, *Industr. Engng Chem. (anal. Edn.)*, 1939, 502.

Determination of Quinine and Strychnine. The assay of the B.P. for strychnine is unsatisfactory with old samples of the syrup, owing to impure strychnine being obtained. In order to obtain pure strychnine, dissolve this residue in 10 ml. of N/1 hydrochloric acid and filter through a 9 cm. filter paper into a separator. Wash the flask and filter paper with three further quantities of 5 ml. of N/1 hydrochloric acid and then with 25 ml. of a saturated solution of sodium chloride. Repeat the extraction of the filtered liquid by shaking with five successive quantities of 25 ml. of chloroform and continue the B.P. process of separation to the same stage as above and weigh the residue, which should be almost white.—N. Evers and W. Smith, *Quart. J. Pharm.*, 1936, 397.

A tentative method for the separation of quinine and strychnine in liquid preparations is described in *Methods of Analysis (A.O.A.C. 1940, 592)*. The extracted and weighed mixed alkaloids are dissolved in 50 ml. of 10% sulphuric acid, 5 ml. of potassium ferrocyanide solution (4%) added drop by drop, and after standing for some hours, filtered and the precipitate washed with 5% sulphuric acid. The precipitate is immediately treated with ammonia solution and chloroform, the solution extracted with chloroform and the alkaloids transferred to 20% sulphuric acid. The ferrocyanide precipitation and extraction with chloroform is repeated, and the chloroform evaporated, the residue of strychnine dried and weighed and checked by titration to methyl red indicator. The combined two acid filtrates and washings from the ferrocyanide precipitation is made ammoniacal, extracted with ether-chloroform, and the quinine finally dried at 120° to 130°. The quinine may be checked by dissolving in alcohol, adding 1 ml. in excess of the quantity of N/50 sulphuric acid necessary to produce a yellow colour to bromo-cresol purple indicator, evaporating to low bulk, cooling and collecting the separated quinine sulphate, washing with water and back titrating the filtrate and washings.

Ferri Sulphas (B.P.). $\text{FeSO}_4 \cdot 7\text{H}_2\text{O} = 278.0$. By titration with N/10 potassium permanganate, it should contain not less than 99% of $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$. The U.S.P. XII salt contains from 54.36 to 57.07% of anhydrous ferrous sulphate, corresponding to not less than 99.5% of the heptahydrate.

Tabellæ Ferri Sulphatis (U.S.P. XII). Contain 95 to 110% of the labelled amount of $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, including all tolerances. Assayed by dissolving a weighed quantity of powdered tablets in recently boiled and cooled water and dilute sulphuric acid, filtering from insoluble matter, and titrating immediately with N/10 ceric sulphate using orthophenanthroline indicator.

Ferri Sulphas Exsiccatus (*B.P. Add. VI*). Contains not less than 77% of FeSO_4 .

Ferrum (*B.P. Add. I*). The fine bright wire should have a diameter of about 0.1 mm. and contain not more than 200 parts of arsenic per million. Much of the wire on the market contains more arsenic than the *B.P.* allows.

Determination of Iron. Small proportions of iron can be determined by means of ammonium nitrosophenylhydroxylamine (*syn.* Cupferron), $\text{C}_6\text{H}_5\text{N}(\text{NO})\text{ONH}_2$. The reagent is used as a 5% solution in water, and should be filtered if necessary. The reagent becomes dark-coloured on long storage, and the solution also gradually becomes darker but keeps satisfactorily for several days. The solution containing about 0.1 g. of iron in 150 ml. to 200 ml. is strongly acidified with hydrochloric acid, and the reagent solution added with constant stirring until a white precipitate of nitrosophenylhydroxylamine begins to form. The brownish-red precipitate of the iron compound is collected, washed several times with dilute hydrochloric acid containing a few drops of the reagent, then with diluted ammonia solution (5% *w/v* of NH_3) to remove excess Cupferron and convert the iron to ferric hydroxide, and, finally, ignited. Each gramme of Fe_2O_3 is equivalent to 0.699 g. of Fe.

Ferrum Redactum (*B.P.*). Contains not less than 80% of metallic iron. Assayed by interaction with a hot copper sulphate solution and titration of the filtered and acidified liquid with N/10 potassium permanganate. **Ferrum Reductum**, *U.S.P. XII*, should contain not less than 90% of metallic iron; interaction at boiling-point with corrosive mercuric chloride is used for assaying, followed by adjustment to volume and titration of an aliquot part of the filtered liquid with N/10 potassium permanganate. The *Fr. Cx.* 1937 substance by similar assay is of the same standard.

Ferrum pulveratum, *P.G. VI*, contains not less than 97.6% of iron, and **Ferrum redactum**, *P.G. VI*, should contain not less than 96.5% of iron or not less than 90% of metallic iron. **Ferrum reductum**, *P. Helv. V*, contains not less than 90% of metallic iron; it is assayed by interaction with a boiling solution of mercuric chloride and titration of the filtrate with potassium permanganate solution.

Assay of Reduced Iron. The copper sulphate method for the determination of metallic iron in reduced iron has been shown to yield inaccurate and variable results. The modification of the Wilner-Merck process suggested yields consistent results which reflect the actual content of metallic iron in the sample. The method recommended is as follows:—To approximately 0.5 g. of sample in a clean, dry 100 ml. graduated flask add 2.5 g. of mercuric chloride (sulphide-free) and about 50 ml. of recently boiled and cooled distilled water. Boil gently for 20 minutes (avoiding excessive frothing) with frequent shaking, make the volume up to 100 ml. with recently boiled and cooled distilled water, cork the flask and cool. When cold, adjust the volume to 100 ml., shake well, allow the precipitate to settle, filter rapidly into a clean, dry conical flask, pipette 50 ml. of the filtrate into 100 ml. of dilute sulphuric acid in which 2 g. of manganese sulphate has been dissolved, and titrate with N/10 potassium permanganate solution.—Hartley, Linnell, Read and Rolfe, *Q. J. Pharm.*, 1935, 100.

Determination of Traces of Lead and Copper in Medicinal Iron Preparations. To 2 g. of sample in a 350 ml. hard glass flask add 5 ml. of water and 10 ml. of sulphuric acid. Heat gently, add slowly 10 ml. of 30% hydrogen peroxide (100 vols.), and boil. Add more hydrogen peroxide as necessary to oxidise the organic matter completely, as indicated by the absence of charring when all the excess water has been boiled off. Cool, add 50 ml. of water and 10 ml. of hydrochloric acid, and boil until a clear solution is obtained. Cool and add a solution of 10 g. of citric acid in 50 ml. of water and

30 ml. of strong solution of ammonia. Cool and neutralise to litmus paper with dilute solution of ammonia, adding a further 10 ml. of the dilute ammonia solution. Transfer to a separator and extract three times with 10 to 15 ml. portions of a 0.1% *w/v* solution of diphenylthiocarbazone in chloroform. Each extract is washed in a second separator with about 20 ml. of water, transferred to a small flask and the chloroform evaporated. Add 0.5 ml. of sulphuric acid to the residue and destroy organic matter by heating with a few drops of nitric acid, then remove nitric acid by adding a few drops of water to the cooled solution and heating until white fumes appear. The solution contains all the Cu and Pb. Dilute with water, add 1 g. of citric acid and 4 g. of ammonium acetate, and, when solution is complete, make slightly alkaline with ammonia and dilute with water to 100 ml. To determine the Cu, transfer 25 ml. to a Nessler glass, neutralise to litmus with glacial acetic acid, adding 2 ml. in excess, dilute to 100 ml. with water and add 1 ml. of a 0.1% *w/v* solution of dithio-oxamide in alcohol (95%). Compare the colour produced with that obtained with a solution containing 1 g. of ammonium acetate and a suitable quantity of standard copper sulphate solution containing 0.00001 g. of Cu per millilitre. The amount of copper solution used should not exceed 6 ml. otherwise a smaller amount of the original solution must be used. The Pb is determined by transferring 25 ml. of the original solution to a Nessler glass, adding 1 ml. of 10% *w/v* KCN solution and a little dilute ammonia, diluting to 50 ml. with water, adding 0.1 ml. of 10% sodium sulphide solution and matching in the ordinary way against the B.P. dilute solution of lead PbT, using an auxiliary solution containing 1 g. of ammonium acetate, 1 ml. of 10% *w/v* potassium cyanide solution and the same amount of Cu as is known to be contained in the primary solution. The amount of standard lead solution used must not exceed 10 ml.—N. L. Allport and G. H. Skrimshire, *Quart. J. Pharm.*, 1932, 460.

Traces of lead may be separated from considerable quantities of iron by extracting the iron, as ferric chloride, with ether from solution in 25 to 27% *w/v* hydrochloric acid.—A. D. Powell and G. F. Hall, *Quart. J. Pharm.*, 1932, 454.

Minute amounts of copper in the presence of iron and certain other metals can be determined colorimetrically by means of diethyldithiocarbamate and extraction with carbon tetrachloride.—L. A. Haddock and Norman Evers, *Analyst*, 1932, 495.

FILIX MAS

Filix Mas (B.P.). Contains not more than 2% of other organic matter. Crystals of calcium oxalate should be absent, and it should yield not more than 6% of ash and 2% of acid-insoluble ash. *Aspidium*, *U.S.P. XII*, on extraction with ether, shaking with barium hydroxide solution, acidifying with hydrochloric acid, extracting with ether, evaporating and drying the residue at 100°, yields not less than 1.5% of crude filicin; acid-insoluble ash, not more than 3%. *Rhizoma Filicis*, *P. Helv. V*, contains not less than 1.8% of crude filicin when determined by applying the usual baryta process to the residue obtained after percolation of the drug with ether.

Extractum Filicis (B.P.). Contains from 24 to 26% *w/w* of filicin. Sp. gr., not less than 1.000. n_{D40° , not less than 1.492. Determined by the B.P. method by shaking 5 g. in 40 ml. of ether with 100 ml. of barium hydroxide solution; 87 ml. of the separated filtered aqueous liquid (= 4 g. of extract) is acidified with hydrochloric acid, and extracted with 30, 20 and 15 ml. portions of ether; the filtered and evaporated ether extracts are dried at 100° and weighed as filicin. *Oleoresina Aspidii*, *U.S.P. XII*, yields not less than 24% of crude filicin. Sp. gr., not less than 1.00 at 25°.

Extractum Filicis, *P.G. VI*, should contain not less than 25% o crude filicin.

Assay of male fern by estimating the phloroglucosides with silver.—*Pharm. J.*, 1930, 321.

Biological Assay. The principles of an assay of extract of male fern is described, and on the basis of about 1000 earth worms a characteristic curve has been determined showing the relation between doses of extract and mortality.—F. Schönhayder, *Quart. J. Pharm.*, 1939, 975.

FENICULUM

Foeniculum (B.P.). Contains not more than 2% of other organic matter and yields not more than 12% of ash. The *N.F. VII* allows a limit of 4% of foreign organic matter for Foeniculum, and not more than 1.5% of acid-insoluble ash. Fructus Foeniculi, *P.G. VI*, is required to yield not less than 4.5% of volatile oil.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined fennel seed as the dried fruit of cultivated varieties of *Foeniculum vulgare* Hill. Required to contain not more than 9% of total ash, and not more than 2% of ash insoluble in hydrochloric acid.—*S.R.A., F.D. No. 2, Rev. 5, Nov. 1936.*

Oleum Foeniculi (B.P.C.). Using a crystal of congealed oil of anise to induce crystallisation, the f.p. (by the *B.P.* method employed for Oleum Anisi) is not below 3°. Sp. gr., 0.960 to 1.000. α_D , +4° to +24°. n_{D20° , 1.525 to 1.550. The *U.S.P. XII* uses a small crystal of the substance being tested or rubs the inner walls of the tube to induce congelation in determining the f.p. of Oleum Foeniculi, which should not fall below 3°. Sp. gr., 0.953 to 0.973 at 25°. n_{D20° , 1.5280 to 1.5380. α_D at 25°, +12° to +24°.

FORMALDEHYDUM (LIQUOR)

Liquor Formaldehydi (B.P.). Contains 37 to 41% w/v of CH_2O . Sp. gr., 1.080 to 1.095. Estimated by heating on a water-bath with hydrogen peroxide and N/1 sodium hydroxide and back titrating the excess of alkali with N/1 sulphuric acid to phenolphthalein, a blank titration being performed. Liquor Formaldehydi, *U.S.P. XII*, should contain not less than 37% w/v of H·CHO; bromothymol blue indicator is used for the titration.

Soluté Officiel de Formaldéhyde, *Fr. Cx.* 1937, is assayed by the following method:—5 ml. of 1% solution and 35 ml. of potassium iodo-mercurate solution are shaken for five minutes with 20 ml. of sodium hydroxide solution; after 15 minutes, and while cooling, the mixture is acidified with dilute hydrochloric acid, the precipitated mercury dissolved in 20 ml. N/10 iodine and back titrated with N/10 sodium thiosulphate; a content of not less than 35% should be indicated. Formaldehyd solutus, *P.G. VI*, should contain at least 35% of H·CHO, determined by the following method:—About 1 g. of solution, accurately weighed, is placed in 100 ml. flask containing 2.5 ml. of water and 2.5 ml.

of N/1 potassium hydroxide. After shaking, make up to 100 ml. 10 ml. of the solution is now mixed with 50 ml. of N/10 iodine and 20 ml. of N/1 potassium hydroxide added. After 15 minutes, add 10 ml. of dilute sulphuric acid, and titrate with N/10 sodium thiosulphate. For every 0.1 g. of formaldehyde solution, at least 23.3 ml. of N/10 iodine is required, so that for the saturation of the excess iodine at most 26.7 ml. of N/10 sodium thiosulphate is necessary. This represents a content of at least 35% formaldehyde (1 ml. of N/10 iodine = 0.001501 g. of formaldehyde, using starch as indicator).

Formaldehydum solutum, *P. Helv. V*, should contain 35 to 36.5% of $\text{H}\cdot\text{CHO}$ and is assayed as follows:—Dilute about 6 g. with water to 100 ml.; to 25 ml. add 3 drops of thymolphthalein and neutralise with N/1 sodium hydroxide to produce a blue colour. Add a freshly prepared solution of 6.5 g. of solid sodium sulphite in 25 ml. of water made neutral to thymolphthalein with N/1 sodium hydroxide, shake gently and titrate with N/1 hydrochloric acid until the solution is completely decolorised. Each millilitre of N/1 HCl is equivalent to 0.03002 g. of $\text{H}\cdot\text{CHO}$.

In the assay process of *P. Helv. V* the direction to neutralise the sodium sulphite solution with alkali is incorrect. It should be neutralised to thymolphthalein with N/1 hydrochloric acid.—L. Rosenthaler, *Schweiz. ApothZtg*, 1935, 617.

The specification of the Association of British Insecticide Manufacturers (Bulletin No. 82: Ministry of Agriculture and Fisheries) requires Liq. Formaldehyde to be a colourless solution, neutral or faintly acid, containing not less than 36% nor more than 40% w/v formaldehyde.

In dilute solutions formaldehyde may be determined by admixture with potassium cyanide solution, addition to acidified silver nitrate solution, adjusting to volume, filtration and back titration of an aliquot with N/10 ammonium thiocyanate solution, a blank titration omitting the test solution being made.

Formaldehyde and acetaldehyde can be distinguished and determined, when mixed, with dimedone (dimethyldihydroresorcinol).—M. V. Jonescu and H. Slusanschi, *Bull. Soc. Chim.*, 1933, 53, 909.

Determination of Formaldehyde in Tablets. A colorimetric method of estimating formaldehyde and paraformaldehyde in tablets, using Schiff's reagent. The results obtained from commercial samples varied from 0.021 g. to 0.002 g. in commercial formaldehyde and menthol tablets weighing 0.791 g. and 0.69 g. respectively. An average content appears to be about 0.01 g.—N. Evers and C. M. Caines, *Yearb. Pharm.*, 1921, 321.

Paraformaldehydum (B.P.C.). By the oxidation method used for Liquor Formaldehydi, it contains not less than 95% of $(\text{CH}_2\text{O})_3$. Ash, not more than 0.1%. The *U.S.P. X* also required a purity of 95%.

Paraldehydum (B.P.). Sp. gr., 0.998 to 1.000. Distillation range, not more than 10% below 123° , the remainder between 123° and 126° . M.p., not below 11° . Complies with limit tests for acidity, acetaldehyde and peroxidised compounds. Paraldehydum, *U.S.P. XII*, should comply with purity tests for impurities derived from fusel oil, amyl alcohol, sulphate, chloride, free acid and acetaldehyde.

The analytical examination of paraldehyde is described, including a procedure for its determination in cases of paraldehyde poisoning.—D. J. T. Bagnall, A. Smith and A. R. Tankard, *Analyst*, 1939, 857.

GELATINUM

Gelatinum (B.P.). A 2% *w/v* hot aqueous solution is odourless and sets to a transparent or translucent jelly on cooling. Sulphur dioxide limit, 1000 parts per million. Ash, not more than 2%. The *U.S.P. XII* sulphur dioxide limit for Gelatinum is 0.004%, by distillation with phosphoric acid into N/10 iodine and precipitation with barium chloride. The *P. Helv. V* allows 0.05% SO_2 in Gelatina animalis.

A British Standard Specification (B.S.S. No. 757—1937), has been issued by the British Standards Institution describing methods for testing gelatins. The specification describes both physical tests, which are mainly determined by the degree of hydrolysis to which the raw material was subjected, and chemical tests, which are concerned with freedom from associated substances. The former include determinations of the jelly strength, viscosity, melting-point, foam, water absorption, solubility, keeping quality, colour and clarity, pH. Chemical determinations described include moisture, grease, ash, sulphur dioxide, chlorides, arsenic and heavy metals.

GELSEMIUM

Gelsemium (B.P.C.). Contains not more than 2% of foreign organic matter. The *N.F. VII* allows the same limit of foreign matter; acid-insoluble ash limit, 2%.

A standard of 0.5% total alkaloids for the root, and 0.05% for the tincture has been suggested.

For a lengthy account of the work of L. E. Sayre, C. W. Moore and others (1911) on the gelsemium alkaloids, also the suggestion to use the name *sempervirine* to replace the amorphous gelsemine, see *Yearb. Pharm.*, 1920, 10.

Identification of Gelsemium. It does not contain aesculin. The fluorescent body is scopoletin (aesculetin-5-methyl ether). If 0.5 g. of the ground drug be heated in a tube with chloroform, the mixture filtered and the filtrate shaken with water to which a few drops of dilute ammonia have been added, the aqueous layer on separation shows a distinct blue fluorescence, indicating presence of scopoletin.—F. Tutin, *Pharm. J.*, i/1912, 157.

The alkaloidal substances in gelsemium root are, according to L. E. Sayre (*Drugg. Circ.*, 1919, 63, 423), the crystalline alkaloids gelsemine and sempervirine, the former being white and the latter reddish-brown, and also the two amorphous alkaloidal substances gelsemidine and gelsemoidine. Gelseminine is the name given often to a mixture of the amorphous bases, which are stated to be mainly responsible for the physiological action of gelsemium. The root also contains non-alkaloidal colour substances.

Assay. Introduce 10 g. of the root and 5 g. of acid-washed sand, both in No. 60 powder, into a pear-shaped separating funnel of about 300 ml. capacity, and add 100 ml. of a mixture of three volumes of ether and one volume of chloroform, shake well and set aside for ten minutes; add 5 ml. of dilute solution of ammonia B.P., and shake for one minute at ten-minute intervals during one hour. Insert a plug of cotton wool into the stem of the funnel and allow the liquid to percolate into another separating funnel. When the liquid ceases to flow, pack the drug firmly and continue the percolation with further quantities of the solvent until complete extraction of the alkaloids is effected. Test for complete extraction by evaporating 2 ml. of percolate, collected separately in a dish, dissolving the residue in a few drops of 0.1 N sulphuric acid and adding one drop of 0.1 N iodine. No precipitate or turbidity should form. To the percolate add 30 ml. of N sulphuric acid, shake well, allow to separate and run off the lower layer. Continue the extraction of the alkaloids with 10 ml. portions of 0.1 N sulphuric acid until extraction is complete. Wash the mixed acid solutions with about 10 ml. of chloroform and run off the latter into a second separating funnel containing 20 ml. of 0.1 N sulphuric acid, shake, allow to separate and reject the chloroform. Repeat the washing of the liquid in the

first separating funnel with two further quantities of 5 ml. each of chloroform, transfer each in turn to the second separating funnel, wash with the same aqueous acid liquid, allow to separate and reject the chloroform as before. Transfer the acid liquid from the second to the first separating funnel, make just alkaline with dilute solution of ammonia B.P. and add 2 ml. in excess; shake with successive portions of chloroform until complete extraction of the alkaloids is effected, washing each chloroform extract with the same 20 ml. of water contained in another separating funnel. Distil off the chloroform, add 2 ml. of absolute alcohol to the residue, evaporate and dry at 60° for thirty minutes. Dissolve the residue in 2 ml. of alcohol 95%, warming until dissolved, add 2 ml. of 0.1 N sulphuric acid and 10 ml. of water, cool and titrate with 0.1 N sodium hydroxide from a microburette, using methyl red as indicator. Each ml. of 0.1 N acid is equivalent to 0.0366 g. of the alkaloids of gelsemium calculated as gelsemine.—Poisons Sub-Committee of the Analytical Methods Committee, *Analyst*, 1941, 108.

Biological Assay. A method using pigeons is recommended and fully described.—B. V. Christensen and L. G. Gramling, *J. Amer. pharm. Ass.*, 1938, 1208.

GENTIANA

Gentiana (B.P.). Contains not more than 2% of foreign organic matter. Water-soluble extractive, not less than 33%. Ash, not more than 6%. Gentiana, *U.S.P. XII*, should yield not less than 30% of water-soluble extractive; moisture, not more than 15%; limit of foreign matter, 2%.

Calumba (B.P. Add. I). Foreign organic matter, not more than 2%. Ash, not more than 9%. Alcohol (60%) soluble extractive, not less than 12%. Calumba, *N.F. VII*, should contain not more than 1% of foreign matter and yield not more than 2.5% of acid-insoluble ash.

GLYCERINUM

Glycerinum (B.P.). $C_3H_8O_3 = 92.06$. Sp. gr., 1.260 to 1.265 (corresponding to from 98 to 100% of $C_3H_8O_3$). $n_{D_{20}^0}$, 1.470 to 1.473. Ash, not more than 0.01%. Glycerinum, *U.S.P. XII*, contains not less than 95% of $C_3H_8O_3$; sp. gr. at 25°, not below 1.249; 5 ml. complies with a test for carbonisable substances.

Glycérine Officinal, *Fr. Cx.* 1937, contains about 3% of water; sp. gr. at 20°, not less than 1.255. Glycerinum, *P.G. VI*, contains from 84 to 87% of anhydrous glycerin; sp. gr., 1.221 to 1.231. Glycerinum, *P. Helv. V*, has a sp. gr. of 1.224 to 1.234 and contains from 84 to 88% of $C_3H_5(OH)_3$, whilst Glycerinum concentratum has a sp. gr. of 1.260 to 1.266 and contains at least 98% of $C_3H_5(OH)_3$.

Detection of Glycerin. By oxidation with permanganate and treatment with Schiff's reagent, glycerin gives a positive coloration in 0.04% solution. The common organic acids do not interfere.—*J. chem. Soc. Abstr.*, ii/1925, 162. See also *Analyst*, 1926, 382.

The identification of glycerin by a bacterial method.—A. Castellani and F. E. Taylor, *J. trop. Med. (Hyg.)*, Oct. 15, 1924, 271.

The following test is based on oxidation to dihydroxyacetone and conversion of the latter to pyrotartaric aldehyde. 2 drops of the solution to be tested is placed in a test-tube which is then filled with bromine vapour, covered, and

heated for ten minutes at 85° to 90° . The cover is removed, heating is continued for 15 minutes, and a crystal of sodium sulphite is added to remove all traces of bromine. 2 to 3 ml. of sulphuric acid is added carefully, with simultaneous cooling, followed by a little solid metahydroxybenzoic acid and the mixture is heated for 15 minutes at 65° to 70° . A green fluorescence shows the presence of glycerin. The sensitivity is 5 γ in 0.05 ml. of solution. The reaction can be observed in presence of six times the amount of glycol or glucose, or twice the quantity of sucrose, but levulose causes more interference.—E. Eegriwe, *Z. anal. Chem.*, 1935, 31.

Determination. Reflux a mixture of 10 ml. approximately 0.025 M glycerin solution, 50 ml. N/10 ceric sulphate and 50 ml. 2N sulphuric acid for one hour. Cool, add 1 ml. of 0.01% aqueous solution of xylene-cyanol FF and titrate the excess of ceric sulphate with N/10 ferrous ammonium sulphate. This method gives high results if the glycerin concentration is less than 1 g. per litre. Sodium hypobromite has also been used in estimating glycerin. Quantitative oxidation to carbon dioxide and water is obtained when 15–30 ml. N/10 sodium hypobromite solution containing not less than 8 g. per litre of sodium hydroxide is used, in excess. The mixture is boiled for 90 minutes and the excess hypobromite assayed iodometrically.—B. Cuthill and C. Atkins, *J. Soc. chem. Ind., Lond.*, 1938, 89.

Determination by Means of Periodates. An excess of solid potassium periodate is added to the neutral solution, the mixture is shaken for 20 minutes and the formic acid titrated with alkali hydroxide using methyl red. The method is applicable in the presence of substances which do not react with periodic acid in the cold or of substances which react but do not give acids or alkalis.—M. A. Malaprade, *Bull. Soc. chim. Fr.*, 1937, 906.

Garrratt (*Drugs and Galenicals*) recommends the method of Shukoff and Schestakoff for determination of glycerin in resorcin ointment:—To a solution with slight excess of sulphuric acid and filtered, add a slight excess of potassium hydroxide solution and evaporate not above 80° to a syrup. Mix with 20 g. of anhydrous sodium sulphate and extract with acetone for 4 hours in a thimble and Soxhlet; evaporate, and dry at 75° to 80° .

Ethylene Glycol: Detection in the Presence of Glycerin. To 10 ml. of test sample add 2 ml. of nitric acid and evaporate to 1 ml., then add 5 ml. of 20% w/v ammonium chloride and allow to cool. Make alkaline by adding, 1 ml. at a time, 10% sodium hydroxide until there is a slight smell of ammonia. Boil off the free ammonia and add 1 ml. of 10% w/v barium chloride. After cooling the mixture for about 15 minutes, filter and wash with about 5 ml. of water. Rinse the precipitate into a boiling tube with 5 ml. of water, add 7.5 ml. of 2N sulphuric acid and heat to boiling. Cool and filter. The filtrate is treated with 0.6 N permanganate until no more is decolorised in the cold and is then boiled. Any further decolorisation shows the presence of oxalic acid, that is of glycol, in the original product. The test will detect 1% of glycol in water or 3% in a mixture of 70% of glycerin and 27% of water.—A. W. Middleton, *Analyst*, 1934, 522.

Before applying the above test triethanolamine must be removed and the following method is suggested. To the sample containing triethanolamine and ethylene glycol add 8 ml. of water, 2 ml. of 50% sulphuric acid and 5 ml. of 30% solution of phosphotungstic acid. Allow to stand in a refrigerator for 3 days, filter, evaporate to small bulk with excess of barium carbonate, extract with ethyl alcohol and evaporate the alcohol.—C. J. Eastland, N. Evers and T. F. West, *Analyst*, 1937, 266.

Determination of Ethylene Glycol. Mix 50 ml. 0.1 N potassium permanganate, 10 ml. 0.025 M glycol solution and 30 ml. 4N sodium hydroxide; stand 1½ hours, add 50 ml. 4N sulphuric acid and stand for a further hour. Finally, add 10 ml. 10% potassium iodide and titrate liberated iodine with thiosulphate. Repeat omitting glycol.—R. Cuthill and C. Atkins, *Analyst*, 1938, 259.

GLYCYRRHIZA

Glycyrrhiza (B.P.). Water-soluble extractive, not less than 20%. Ash limits: peeled drug, not more than 6%; unpeeled drug, not more than 10%. Acid-insoluble ash, not more than 2.5%. Powdered liquorice B.P. is the powder of the peeled drug;

a powder of the unpeeled drug is not used except when expressly named. Glycyrrhiza, *U.S.P. XII*, yields not more than 2.5% of acid-insoluble ash.

Fr. Cx. 1937. Determination of glycyrrhizin in Suc de Régliſſe. Dissolve 3 g. dried at 100° in 30 ml. of water with 5 drops of ammonia solution and filter; to 20 ml. of filtrate (2 g. dried drug) add 2.5 ml. of sulphuric acid and after 24 hours filter, and wash the residue with 30 ml. water; dissolve the residue in 2 ml. ammonia solution, filtering through the same filter and washing with water made ammoniacal (5 drops to 10 ml.). Evaporate and dry at 100° for one hour, weigh and add correction for the glycyrrhizin dissolved in mother liquor and washings (0.04 g. for 40 ml. total). The glycyrrhizin ammonia should be not less than 10%.

The name "glycyrrhizin" applies to the sweet substance found in liquorice root, a mixture of calcium and potassium glycyrrhizates.

Tschirch discovered that glycyrrhizic acid is the diglycuronic acid ester of glycyrrhetic acid. It has glycosidal properties. Glycuronic acid is of importance in animal life—an unexpected fact, since the most varied sugars are at the disposal of a plant if it wishes to form glycosides.

A minimum of 9% of "glycyrrhizin" should be present in normally prepared edible juices—they should not contain more than 18% of sugars, reducing and non-reducing. In order to determine whether the starch be actual or added, the sample should be powdered, extracted with water and the residue taken up with 3% ammonia solution. The insoluble matter should never exceed 6%. Examine this under the microscope to trace source of starch, i.e., whether added or of the same character as that in the root. The amount not dissolved in 70% alcohol should not exceed 16.5%. Gum should never be present in pure liquorice juice.—Parry, *Chem. & Drugg.*, i/1911, 183.

GOSSYPIUM

Gossypium Absorbens (*B.P.C.*). Absorbent cotton wool. A thin layer, equivalent to about 0.5 g. for an area of 70 sq. in., when, viewed between glass plates, by transmitted light, is not more neppy than the standard sample kept at the Manchester Testing House. 1 g. compressed to about 20 ml. and placed lightly on water at 20° sinks or becomes saturated within 10 seconds. Average length of staple, not less than $\frac{1}{8}$ inch. Water-soluble extractive, not more than 0.5%. Ash, not more than 0.5%.

The greasy material on absorbent cotton wool consists mainly of fatty acids with a fairly large proportion of unsaponifiable matter. In commercial samples this substance is present in sufficient quantity to cover the fibres with a film of molecular thickness and the absorbency will be greater or less according to whether the fatty acids are oriented with the carboxyl groups outwards or inwards. In the latter case wetting is due to rupture of the film consequent upon the swelling of the fibres under the influence of water vapour diffusing through the grease, and is a slower process. The orientation of carboxyl groups in the grease can be affected by external conditions, but samples impregnated with purely paraffinoid substances show only the second type of wetting.—R. Maxwell Savage, *J. Soc. chem. Ind., Lond.*, 1934, 379.

Surgical Dressings. The *B.P.C. Supp. IV* directs that all weights and counts of yarn refer to those obtained under standard humidity conditions, the materials being exposed to an atmosphere of 65 to 70% relative humidity for a period of at least 6 hours.

Prescribed Methods.

To avoid error due to comparatively large spaces between threads in fabrics of open texture, a length of ten inches shall be counted for number of threads per inch.

Elasticity is determined by applying to the movable end of crêpe and adhesive bandages (the other end being held in a fixed grip) by means of a spring dynamometer, a tension of 6 pounds per inch width. The tension is maintained for 1 minute and the stretched length measured; the bandage is then released immediately and measured after 5 minutes, the length being expressed as percentage of the stretched length.

Water-soluble Extractive is determined by the loss in weight after well washing the dried sample from the moisture determination, followed by hand wringing 12 successive times, any loose threads, which should be collected by passing the washing through a fine sieve, being added. The residue is dried at 100° and weighed. For wool and union fabrics the wash water should be at 45° to 50°.

Foreign Matter. By continuous extraction with a solvent, such as chloroform, ether, carbon tetrachloride, of the dried sample (wool should be further extracted with alcohol); after airing off the solvent, the cloth is washed as in the water-soluble extractive determination. If starch is present, it is soaked in 0.5% malt extract solution at 50° and then heated to 70° for 15 minutes, followed by washing with hot running water 12 times as before. The residue, with any collected loose threads or fibres is dried at 100°, and weighed. In wool and grey cotton an allowance of 3% is made for loss of natural impurities. The cleaned sample is ashed to indicate that all insoluble matter is removed and 0.2% allowed for the natural ash.

Cotton and Wool. The dried material after extraction of the foreign matter is boiled in 5% sodium hydroxide solution for 10 minutes, removed, the treatment repeated and then well washed. The residue plus loose threads and fibres, collected as before, is dried at 100° and weighed as dry cotton. For unbleached cotton an allowance for loss of natural constituents of 4% is made. The loss in weight is that of dry wool. Standard moisture regains of 8.5 and 16% respectively are added.

Tensile Strength. Six specimens of the material of the specified width and measuring 7 inches held between the jaws of a Goodbrand machine having a constant rate of traverse of 18 inches per minute, are submitted to test in the machine after exposure to an atmosphere of 65 to 70% relative humidity for at least 6 hours. The average of the minimum breaking load for the 6 specimens is the tensile strength.

Carbasus Absorbens (B.P.C.). Absorbent gauze. Water-soluble extractive, not more than 0.5%. Weight per sq. yd., not less than 180 gr. Average number of threads per inch, not less than 19 in the warp and 15 in the weft. A test for absorbency is included.

Carbasus Absorbens in Tænia (B.P.C.). Complies with the same standard as Carbasus Absorbens for material and water-soluble extractive. Weight of a piece 2 inches × 6 yards, not less than 190 grains. Average number of threads per inch, not less than 30 in the warp and not less than 25 in the weft. A test for absorbency is included.

Cellulosum Ligni (B.P.C.). Cellulose wadding. Superficial area, not less than 1500 sq. in. per pound. Moisture limit, 10%. Ash limit, 0.5%. Chloroform extractive, not more than 1%. 1.5 g. compressed to about 20 ml. and placed on water at 20° sinks or becomes saturated within 5 seconds.

Curatio Normalis III (B.P.C. Supp. II). The unstretched spread fabric, after removal of the medicated pad, weighs not less than 4.4 gr. per sq. inch and after the further removal of the rubber adhesive compound and other foreign organic matter, not less than 2.2 gr. per sq. inch (correction being made for natural moisture regain). The fabric should be of two-fold crêpe yarn,

having not less than 44 turns one way and standard two-fold yarn the other way, both being of good uniform grade. Threads per sq. inch, not less than 70, when fully stretched in the elastic direction, and on immediate release returns to a length not more than 80% of the fully stretched length.

Curatio Normalis IV (*B.P.C. Supp. II*). Complies with the same standard for the elastic cotton fabric described under Curatio Normalis III.

Curatio Normalis V (*B.P.C. Supp. II*). The elastic cotton fabric complies with the same standard.

Curatio Normalis VI (*B.P.C. Supp. II*). Complies with the standard for elastic cotton fabric described above.

Linteum Absorbens (*B.P.C.*). Absorbent lint. Water-soluble extractive, not more than 0.5%. Superficial area, 230 to 250 sq. in. per ounce. Minimum average number of threads per inch, 39 in the warp and 24 in the weft. A piece, 3 × 3 in., placed unraised side downwards on water at 20° becomes saturated in 10 seconds.

Tela Carbasi et Gossypii (*B.P.C.*). Gauze and cotton tissue. Superficial area, not less than 1800 sq. in. per pound. The absorbent gauze and absorbent cotton wool comply with the standards for Carbasus Absorbens and Gossypium Absorbens respectively.

Tela Carbasi et Gossypii Capsici (*B.P.C.*). Capsicum tissue. The absorbent gauze should comply with the standard for Carbasus Absorbens, with the exception of the colour and the weft, which has not less than 12 threads per inch. Superficial area not less than 1800 sq. in. per pound.

Tela Carbasi et Ligni (*B.P.C.*). Cellulose tissue. The absorbent gauze should comply with the standard for Carbasus Absorbens, with the exception that the weft has not fewer than 12 threads per inch. The cellulose wadding complies with the *B.P.C.* Cellulosum Ligni standard. Superficial area, not less than 1350 sq. in. per pound.

A summary of the circular C.423 issued by the National Bureau of Standards, U.S. Dept. of Commerce, containing a compilation of methods for the microscopic identification of commercial fibres including paper, jute, cotton, flax rays, silk and wool, is given in *Analyst*, 1939, 425.

Protectives

Fabric of Battiste and Jaconet. 3-inch squares of the material are immersed in a solvent (benzene, toluene, xylene, etc.), heated to boiling and kept boiling if necessary. The cuttings are removed, the swollen proofing removed and the fabric heated in liquid paraffin at a temperature not exceeding 150°. The fabric is shaken and extracted with petroleum ether, any filling removed as for determination of foreign matter, and finally dried at 100°. To the weight allowance for natural moisture regain is made.

Battista (*B.P.C.*). With boiling water, or when heated with steam, battista must show no stickiness or deterioration. Weight

per square yard not less than 5 oz., of the fabric alone not less than 2 oz., and the difference of these not less than 3 oz. Average threads per inch, not less than 104 in the warp and 72 in the weft.

The following alternative specification for Battista *B.P.C.* has been published (see *Pharm. J.*, i/1943, 130). Weight per square yard not less than 5.75 oz.; weight per square yard of the fabric alone not less than 2 oz.; the difference between the weight of the fabric per square yard and the proofed material is not less than 3.75 oz. Average threads per inch, not less than 104 in the warp and 72 in the weft. Tensile strength per 1 inch strip, not less than 40 pounds in the warp and not less than 25 pounds in the weft. The proofing contains not more than 35% of mineral matter.

Emplastrum Adhesivum (*B.P.C. Supp. IV*). Weight per sq. yard, not less than $7\frac{1}{4}$ ounces. Tensile strength of the warp per inch width, not less than 45 pounds. Weight of base cloth, after removal of adhesive, etc., and corrected for moisture regain, not less than $3\frac{3}{4}$ ounces per sq. yard. Weight of adhesive, etc., not less than $3\frac{1}{2}$ ounces per sq. yard. A specification of the quality of the cloth is included. Average number of threads per inch, not less than 72 in the warp, not less than 70 in the weft.

Jaconettum (*B.P.C.*). With boiling water or when heated with steam jaconet must show no stickiness or deterioration. Weights per square yard not less than 6 oz. total, fabric alone 2 oz., and the difference 4 oz. Not less than average number of 104 threads in the warp and 72 threads in the weft per inch. An alternative specification has also been prescribed for Jaconettum *B.P.C.* (see *Pharm. J.*, i/1943, 130).

Sericum Oleatum (*B.P.C.*). Oiled silk. Minimum weights per square yard for oiled fabric 2.5 oz., and for silk fabric alone 0.33 oz. Average number of threads per inch, not less than 120 in the warp and 85 in the weft.

Sericum Oleatum Factitium (*B.P.C.*). A specification has been published for oiled artificial silk for use in place of oiled silk (see *Pharm. J.*, i/1943, 45). Weight per square yard of waterproof fabric, 2.25 to 2.75 oz.; weight of the fabric alone and after allowance for natural moisture regain, not more than 0.85 oz. per square yard. Average number of threads per inch, not less than 100 in the warp and 100 in the weft.

Sindon Oleata (*B.P.C.*). Oiled cambric. Minimum weights per square yard for the oiled fabric 4 oz., for cotton fabric alone 1.5 oz., and the difference 2.5 oz. Average number of threads per inch, not less than 74 in the warp and 68 in the weft.

HEPAR

Extractum Hepatis Siccum (*B.P.*). Should contain not less than one-tenth its weight of sodium chloride and should be

packed in tubes, each containing the equivalent of 225 g. of original liver. *Extractum Hepatis, U.S.P. XII*, complies with the specifications of the U.S.P. Anti-anæmia Preparations Advisory Board, by which satisfactory clinical data regarding treatment of Addisonian pernicious anæmia and evidence that the satisfactory result is produced by the dose given shall be available; the preparation must be labelled with the average dose.

Extractum Hepatis Liquidum (B.P.). 1000 ml. should contain the equivalent of 8000 g. of original liver, not less than the equivalent of 10% *v/v* of 95% alcohol, and not less than 20% *v/v* of glycerin. *Liquor Hepatis, U.S.P. XII*, conforms to specifications of the U.S.P. Anti-anæmia Preparations Advisory Board.

Liver extracts contain chromogenic purine constituents giving a blue colour with urea cyanide reagent followed by Folin's uric acid reagent. Part of the chromogen is precipitable by lead acetate and this fraction was found absent from the liver of a patient dying from untreated pernicious anæmia, but present in that of a patient successfully treated for pernicious anæmia but dying from other causes. The chromogenic purine specifically cures canine black tongue and since both this disease and pellagra are characterised by spinal cord degeneration, which is also associated with pernicious anæmia and about which there have been conflicting reports as to the efficacy of liver extract, it may well be that liver extracts effective in cord degeneration are rich in purine. Some highly potent liver extracts for parenteral injection have very little chromogen activity.—G. E. Shaw, *Quart. J. Pharm.*, 1937, 380.

A reticulocyte response is obtainable in pigeons even with liver extracts which are clinically inactive.—G. E. Shaw and J. Pritchard, *Quart. J. Pharm.*, 1937, 517.

Assay. There is no satisfactory biological test for liver extract. The pigeon method introduced by Vaughan and her colleagues has been investigated by Gurd, *Quart. J. Pharm.*, 1935, 39, who found that when sufficient care is taken to stain the red cells of the pigeon, it becomes impossible to make a sharp distinction between those which have a reticulum and those which have not. If an arbitrary distinction is made of those with a heavy reticulum from those with a lighter one, then no effect on the number of reticulocytes is produced when liver extract is injected.

A method of assay has been developed, using a test upon guinea-pig bone marrow preparations *in vitro* which apparently makes possible the quantitative estimation of anti-anæmic potency of liver concentrates. The method depends upon measurement of the migration of cells from isolated living bone marrow embedded in a coagulum of plasma to which various concentrations of liver extract have been added. At certain optimal concentrations of liver extract the migration is increased and the concentration thus effective is an index of the potency of the liver extract. A curve has been constructed showing the relationship between the dilution of liver concentrates at which maximum migration of cells from bone marrow occurred, and the *U.S.P.* potency of these concentrates. It would appear that this curve may be used for determination of the expected clinical potency of unknown liver extracts.—N. Pace and R. S. Fisher, *J. Pharmacol.*, 1942, 74, 256.

Ventriculus Desiccatus. The following upper limits are suggested:—Ash 5%, calculated on a fat- and moisture-free basis; fat 15% if not defatted, or 5% if the fat is extracted; moisture 5%. It is also desirable that the preparation should be free from organisms giving acid and gas in MacConkey's medium.—K. Bullock, *Quart. J. Pharm.*, 1936, 381.

Assay by Casein Digestion. A valuable guide to the clinical activity of desiccated stomach preparations is provided by their peptic activity and the following method has proved of value for the determination of the enzyme activity of stomach preparations at various stages of manufacture. 0.5 g. of pure casein is dissolved in 40 ml. of water and 20 ml. of N/1 sodium hydroxide by warming on a water-bath. To the resulting solution is added 30 ml. of N/10 hydrochloric acid. The liquid is filtered and the filtrate made up to 100 ml. A weighed quantity of the stomach preparation to be tested, which has been passed through a No. 40 sieve, is shaken for 2 hours with dilute hydrochloric

acid (120 ml. of N/1 acid with water to 1 litre) and filtered. 1 g. of the preparation in 1 litre of acid is usually suitable. To carry out the test, into each of seven test-tubes is placed 1 ml. of pepsin solution followed by 0.7 ml. 0.5 ml. . . . 0.1 ml. of the casein solution. The contents of each tube are diluted to 4 ml. with the diluted hydrochloric acid and are then incubated at 40° for one hour. After incubation 0.5 ml. of saturated ammonium sulphate solution is added to each tube and their turbidities compared as rapidly as possible. The comparison is made by holding the tubes in front of a printed card, the print being a light face Gill Sans type, 8-point size. The tube through which the print is just readable is known as the index tube. The amount of the hog stomach preparation in this tube is that required to digest 0.005 g. of casein and from this the weight of casein digested by 1 g. of preparation may be calculated.—E. E. Rymill and C. A. Macdonald, *Quart. J. Pharm.*, 1937, 323.

Heparin

Assay. The anticoagulant potency of heparin is tested against either freshly drawn blood or various artificial clotting systems which can be clotted when desired. Three methods of assay are described:—(1) The Howell assay as modified by Charles and Scott, in which the degree of clotting in samples of cat's blood containing varying amounts of the unknown is compared with similar samples containing a standard preparation, (2) a new thrombin assay, in which the unknown and standard heparin solutions are titrated against a system consisting of oxalated beef blood and thrombin, using a constant clotting time, and (3) the Fischer assay, in which the clotting time of chicken plasma on addition of thrombokinase is determined for varying concentrations of unknown and standard heparin. Factors which affect the results of the assays are discussed. The crystalline heparins isolated from different species show marked differences in their specific biological activity. It has been found that their relative anticoagulant activities vary with the method of assay.—L. B. Jaques and A. F. Charles, *Quart. J. Pharm.*, 1941, 1.

A simple method of comparing the activity of anti-coagulants is described. Fresh rabbits' blood is added to two series of test-tubes, one containing definite amounts of the anti-coagulant under test, the other definite amounts of a standard solution of the sodium salt of heparin. By comparing the tubes, the activity of the anti-coagulant can be found in terms of the standard preparation. The error is stated not to exceed 10%.—F. Schütz, *Quart. J. Pharm.*, 1941, 45.

HEXAMINA

Hexamina (B.P.). $C_6H_{12}N_4 = 140.1$. Contains not less than 99% of $C_6H_{12}N_4$. Ash, not more than 0.05%. Assayed by boiling with N/1 sulphuric acid until all the formaldehyde produced has been evolved, and back titrating the excess acid with N/1 sodium hydroxide to methyl orange. By the same method Methenamina, *U.S.P. XII*, should contain 99% of the pure substance, after drying over sulphuric acid for four hours.

Tabellæ Methenaminæ et Sodii Biphosphatis (N.F. VII). Contain 92.5 to 107.5% of the labelled amount of methenamine, including all tolerances. Limit tests for aluminium, calcium and ammonium salts are included. Assayed by boiling with dilute sulphuric to remove formaldehyde, subsequent ammonia distillation into N/2 sulphuric acid, and titration with N/2 sodium hydroxide using methyl red indicator.

A tentative quantitative method for the determination of hexamine in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 576)*.

A method for the quantitative determination of hexamine using calcium hypobromite.—E. F. Slowick and R. S. Kelley, *J. Amer. pharm. Ass., Sci. Edn.*, 1942, 15.

HYDRARGYRUM

Hydrargyri Cyanidum (B.P.C. Supp. IV). $C_2N_2Hg = 252.6$. Contains not less than 99% of $Hg(CN)_2$. Residue on ignition, not

more than 0.1%. Limit tests for chloride and mercuric oxycyanide are described. Assayed by addition of sodium chloride and potassium iodide, and titration with N/10 hydrochloric acid to methyl orange.

Carbasus Hydrargyri et Zinci Cyanidi (B.P.C.). Double cyanide gauze contains mercury equivalent to from 0.5 to 1.5% of $\text{Hg}(\text{CN})_2$, and zinc equivalent to from 1.5 to 3% of $\text{Zn}(\text{CN})_2$. A nitric acid extract of the gauze and washings is adjusted to volume; zinc is determined in one portion by the B.P. method for Zinci Sulphas, by precipitation with mercuric ammonium thiocyanate solution and subsequent titration with potassium iodate; mercury is precipitated as sulphide from the remaining portion after neutralisation and just acidifying with hydrochloric acid.

Hydrargyri Iodidum Flavum (B.P.C.). $\text{HgI} = 327.5$. Assayed by interaction with N/10 iodine and potassium iodide, followed by back titration with N/10 sodium thiosulphate; a purity of the dried substance of not less than 99% should be indicated. Loses not more than 0.5% on drying over sulphuric acid, and leaves not more than 0.2% of residue on volatilisation. The N.F. VII specifies that the substance dried over sulphuric acid shall contain 99% of HgI ; residue on volatilisation, not more than 0.1%.

Tabellæ Hydrargyri Iodidi Flavi (N.F. VII). Contain 91 to 109% of the labelled amount of yellow mercurous iodide, including all tolerances. Assayed by dissolving in water and hydrochloric acid and titrating with M/50 potassium iodate using chloroform as indicator.

A tentative quantitative method for the determination of mercurous iodide in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 621)*.

Hydrargyri Iodidum Rubrum (B.P.). $\text{HgI}_2 = 454.5$. After standing for 10 minutes with zinc powder and water and filtering off the amalgam formed, the filtrate and washings are treated with excess N/10 silver nitrate and nitric acid and titrated with N/10 ammonium thiocyanate; not less than 99% of the pure salt should be indicated. Leaves not more than 0.1% of residue on volatilisation. The N.F. VII assays by titration, in the presence of hydrochloric acid, with M/20 potassium iodate using chloroform as indicator, and requires the substance dried over sulphuric acid to contain not less than 99% of HgI_2 .

Tabellæ Hydrargyri Iodidi Rubri (N.F. VII). Contain 91 to 109% of the labelled amount of red mercuric iodide, including all tolerances. Assayed by dissolving in water and hydrochloric acid and titrating with M/50 potassium iodate, using chloroform as indicator.

Solvellæ Hydrargyri Iodidi (B.P.C.). Contain 8.75 grains of HgI_2 , and 1 tablet in a pint of water gives a 1 in 1000 solution of HgI_2 . Some makers prepare them to contain $8\frac{3}{4}$ grains of anhydrous mercuric potassium iodide ($\text{HgI}_2 \cdot \text{KI}$) with a sufficiency of potassium iodide in excess to make the body $\text{HgI}_2 \cdot 2\text{KI}$. One dissolved in 1 pint of water makes a 1 in 1000 solution of mercuric potassium iodide and each contains 6.4 grains of HgI_2 . A trade custom has developed, however, of making them on various

assumptions, e.g., to contain $8\frac{1}{2}$ grains of the soluble iodide, $\text{HgI}_2 \cdot 2\text{KI}$, which renders the content of mercuric iodide in the solution far less, namely, 5 grains.

To estimate the mercury in tablets of this kind, formalin reduction as recommended by E. Rupp is used. For the iodine, the iodate reaction in presence of strong hydrochloric acid is suitable. $2\text{HI} + \text{HIO}_3 + 3\text{HCl} = 3\text{I}_2 + 3\text{H}_2\text{O}$. The whole matter is well dealt with in a paper by A. J. Jones, *Chem. & Drugg.*, i/1920, 523.

Garratt (*Drugs and Galenicals*) recommends the method of Sage and Stevens (*Chem. & Drugg.*, i/1932, 84). Reflux with 2 g. of zinc filings in acetic acid (50%) for 30 minutes, filter, wash, and dissolve the amalgam in nitric acid; oxidise with permanganate and titrate with N/10 potassium thiocyanate. The iodine may be determined in the acetic acid solution and washings by titration with M/20 potassium iodate in presence of hydrochloric acid.

Hydrargyri Iodidum Viride (B.P.C. Supp. IV). Contains not less than 24.5% of I, determined by interaction with zinc dust and small quantity of water and acetic acid, dilution, filtration, and washing of the insoluble amalgam, followed by titration of the soluble iodide formed, with excess N/10 silver nitrate and N/10 ammonium thiocyanate using ferric ammonium sulphate indicator; Hg content not more than 75%, as shown by solution of the amalgam from the iodine assay in dilute nitric acid, oxidation with potassium permanganate solution and titration with N/10 ammonium thiocyanate.

Hydrargyri Oxidum Flavum (B.P.). $\text{HgO} = 216.6$. Loses not more than 1% when heated at 150° for 1 hour, and then contains not less than 99.3% of the pure substance. Residue on ignition, not more than 0.5%. Assayed by titration in nitric acid solution with N/10 ammonium thiocyanate. The *U.S.P. XII* requires the substance dried to constant weight at 110° to contain 99.5% of HgO .

The temperature of 150° , specified in the *B.P.* as that at which the substance is to be dried for calculating the percentage strength, is too high since marked amounts of mercurous oxide are produced at this temperature. This decomposition and that of the mercurous oxide occurring as an impurity can be minimised by drying at 70° , at which temperature no decomposition takes place.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1933, 406.

Hydrargyri Oxidum Rubrum (B.P.C.). $\text{HgO} = 216.6$. Loses at 150° not more than 1%, and is then of 99.3% purity. Residue on volatilisation, not more than 0.3%. The *N.F. VII* requires the salt dried at 120° to contain not less than 99.5% of HgO .

Hydrargyri Oxycyanidum (B.P. Add. I). $\text{HgO} \cdot 3\text{Hg}(\text{CN})_2 = 974.5$. Contains 20 to 22% of HgO and 77 to 79% of $\text{Hg}(\text{CN})_2$. Loss at 100° , not more than 1%. Residue on ignition, not more than 0.1%. Assayed for mercuric oxide by treatment with sodium chloride and titration with N/10 hydrochloric acid to methyl orange; and for mercuric cyanide by continuing the titration after adding potassium iodide. 1 g. produces a clear solution with 200 ml. of water.

Oxycyanure Mercurique, *Fr. Cx.* 1937, assayed similarly contains 14.4 to 16.35% of HgO and 83.75 to 84.63% of mercuric cyanide. *Hydrargyrum oxycyanatum*, *P.G. VI*, contains

33.3 to 35.2% of $\text{Hg}(\text{CN})_2 \cdot \text{HgO}$, corresponding to 15.37 to 16.25% of HgO and 84.6 to 83.8% of $\text{Hg}(\text{CN})_2$. Hydrargyrum oxycyanatum, *P. Helv. V*, contains from 15.37 to 16.25% of HgO and from 83.75 to 84.63% of total $\text{Hg}(\text{CN})_2$.

Hydrargyri Perchloridum (B.P.). $\text{HgCl}_2 = 271.5$. Contains not less than 99.5% of the pure salt. Residue on volatilisation, not more than 0.1%. Assayed by reduction in presence of potassium iodide with formaldehyde and sodium hydroxide solutions, acidifying with acetic acid and adding excess N/10 iodine and, when the precipitate is completely dissolved, back titrating with N/10 sodium thiosulphate. Hydrargyri Bichloridum, *U.S.P. XII*, after drying for 18 hours over sulphuric acid should contain not less than 99.5% of HgCl_2 . Assayed by precipitation as sulphide, washing and drying at 110° .

In the *B.P.* assay process the addition of 5 ml. of a mixture of 2 vols. of ether and 1 vol. of chloroform enables rapid solution of the precipitated mercury to be effected.—H. Brindle, *Quart. J. Pharm.*, 1932, 432.

Modification of Rupp's Method. The addition of gelatin retains the reduced mercury in a finely divided condition and avoids trouble due to the metal failing to react with iodine owing to aggregation. The mercuric solution is treated with sufficient potassium iodide (about 1 g.) to form a double salt, rendered alkaline with 5N sodium hydroxide solution (an excess of 5 ml. being added) and heated to about 60° . 2 ml. of freshly-prepared warm 2.5% gelatin solution is added and then, with constant swirling, 3 to 4 ml. of solution of formaldehyde. The mixture is cooled to about 20° , acidified with excess of acetic acid, and 25 ml. of N/10 iodine added. The excess of iodine is titrated with N/10 thiosulphate.

In organic compounds of mercury, the organic matter must first be destroyed by heating with concentrated sulphuric acid, the resulting solution and washings being oxidised with bromine water, with subsequent boiling to remove bromine. Readily volatile or stable alkyl compounds are best decomposed by preliminary treatment with pure bromine in a flask provided with a ground-glass air condenser, the resulting mixture being then heated with sulphuric acid. Prolonged heating with sulphuric acid is avoided by adding a few drops of nitric acid.—M. Fitzgibbon, *Analyst*, 1937, 654.

Results obtained by the iodometric method of Rupp are in general inaccurate. The various modifications suggested, such as the use of ether and alcohol, gelatin, etc., to facilitate solution of the mercury, were found to be only partially effective or inconvenient. High results are probably due to reduction of iodine by formic acid produced from formaldehyde by action of alkali and during the reduction of mercuric salt, and present in formalin. To overcome this defect it was found necessary to filter off the mercury before determining it iodometrically. Filtration is facilitated by precipitating with the finely divided mercury some basic magnesium carbonate, which in no way interferes with the assay process.—H. A. Sloviter *et al.*, *Industr. Engng Chem. (anal. Edn.)*, 1941, 890.

Mayer's Reagent. (*Tanret's Reagent* is identical in composition.) Mercuric chloride 13.546 g., potassium iodide 49.8 g., distilled water to 1 litre. This reagent gives a precipitate with alkaloids.

Formerly, methods of volumetric estimation of alkaloids by means of the above were in vogue, but the composition of the precipitates is variable.

Liquor Hydrargyri Perchloridi (B.P.). Contains 0.095 to 0.105% *w/v* of mercuric chloride. Assayed by reduction with formaldehyde, followed by interaction with excess N/10 iodine and back titration with N/10 sodium thiosulphate.

Toxibellæ Hydrargyri Bichloridi Magnæ (U.S.P. XII). Contain an average of 0.42 g. to 0.52 g. of HgCl_2 , with a sufficient quantity of excipient or diluent. Assayed by the process described for mercuric chloride.

Toxibellæ Hydrargyri Bichloridi Parvæ (U.S.P. XII). Contain an average of 0.11 g. to 0.14 g. of HgCl_2 with a sufficient quantity of excipient or diluent.

Hydrargyri Salicylas (B.P.C. Supp. IV). Contains from 54 to 59.6% of Hg. Residue on gentle ignition at about 300° , not more than 0.2%. Assayed by addition of potassium permanganate to a solution of the substance in N/1 sodium carbonate and after 5 mins. addition of sulphuric acid, followed after a further 5 mins. with ferrous sulphate solution. When the precipitate is dissolved, nitric acid is added and titration made with N/10 ammonium thiocyanate using ferric ammonium sulphate indicator. The U.S.P. XII substance should contain from 54 to 59.5% of Hg; determined by heating with sulphuric and nitric acids on a sand-bath until a colourless mixture results, diluting, and titrating with N/10 ammonium thiocyanate. Hydrargyrum salicylicum, P.G. VI, contains not less than 92% of $\text{C}_6\text{H}_5(\text{OH})\text{COOHg}$.

Hydrargyri Subchloridum (B.P.). $\text{HgCl}=236.1$. Should contain not less than 99.6% of the pure substance. Residue on volatilisation, not more than 0.1%. Assayed by shaking in water with N/10 iodine and potassium iodide and titrating with N/10 sodium thiosulphate. Hydrargyri Chloridum Mite, U.S.P. XII, after drying to constant weight over sulphuric acid, contains not less than 99.6% of HgCl . Determined by interaction with iodine and potassium iodide and titration of the excess iodine with sodium thiosulphate.

Finely Divided Calomel (Duret). Dissolve sodium bicarbonate 6 g. and glucose 10 g. in distilled water 80 ml. Then dissolve separately magnesium chloride cryst. 7.5 g. in water 20 ml. Mix the above and add to a third solution consisting of mercuric chloride 11.5 g., hydrochloric acid 10 drops and water 100 ml. Shake well and allow to stand. Carbon dioxide is evolved. When this slackens, warm on a water-bath until no more gas comes off; wash and dry the precipitate. Yield, 10 g. of a light form of calomel, which may be more active for local use.

Calomel made by this formula is similar to the scaly calomel recommended by Burdon Cooper some years ago for ophthalmic use.

Tabellæ Hydrargyri Chloridi Mitis (N.F. VII). Contain 92.5 to 107.5% of the labelled amount of mild mercurous chloride, including all tolerances. Comply with a test for absence of mercuric chloride. Assayed by washing a weighed quantity of powdered tablets with water, and treating the residue with potassium iodide and excess N/10 iodine, finally titrating with N/10 sodium thiosulphate.

Tabellæ Hydrargyri Chloridi Mitis et Sodii Bicarbonatis (N.F. VII). Contain 92.5 to 107.5% of the labelled amount of mild mercurous chloride for tablets containing more than 15 mg., and 90 to 110% for tablets containing 15 mg. or less of mild mercurous chloride, including all tolerances. Assayed by dissolving in dilute acetic acid and proceeding as for mercurous chloride tablets.

An official quantitative method for the determination of mercurous chloride in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 620)*. A tentative quantitative method for the determination of mercurous chloride in calomel ointment is also described. The soluble fillers in the tablets are dissolved in water acidified with acetic acid, and the insoluble portion collected on an asbestos mat and washed with water, alcohol and ether. In the case of the ointment, the base is extracted with chloroform and the insoluble portion collected on asbestos. In either case the asbestos mat is transferred to a flask and potassium iodide and iodine added; after $1\frac{1}{2}$ hours or when the calomel is dissolved, back titration is made with N/10 sodium thiosulphate, adding an excess and readjusting with N/10 iodine, using starch mucilage as indicator.

Hydrargyri Succinimidum (U.S.P. XII). Dried for 18 hours over sulphuric acid, it contains 49·5 to 51% of Hg, corresponding to not less than 98% of $C_4H_4O_2N_2Hg$; determined by titration with ammonium thiocyanate.

Phenylhydrargyri Nitras (B.P. Add. IV). $C_{12}H_{11}O_4NHg_2 = 634\cdot3$. When assayed by digestion with dilute hydrochloric acid, precipitation as sulphide and drying at 110° , it contains not less than 98% of the pure substance. M.p., 185° to 190° , with decomposition, when heated with a rise of temperature of 5° per minute. A limit of mercuric salts and heavy metals is included. Loss over sulphuric acid, not more than 1%.

Hydrargyrum (B.P.). Hg = 200·6. Assayed by titration of the solution in nitric acid with ammonium thiocyanate; should contain not less than 99·5% of Hg. Residue on volatilisation at about 300° , not more than 0·02%. The U.S.P. XII requires Hydrargyrum to leave not more than 0·01% residue on ignition.

Detection of Mercury. Mercury may be detected by means of diphenylcarbazone, $C_6H_5\cdot NH\cdot NH\cdot CO\cdot N : N\cdot C_6H_5$. The reagent is used as a saturated solution in alcohol. The test solution is rendered neutral or very faintly alkaline (pH 7 to 8) by the addition of sodium acetate (about 1 g. of sodium acetate per 10 ml. of solution is usually sufficient), and 1 drop of reagent per 10 ml. of solution is added. In the presence of mercury a violet or blue coloration is produced. The sensitivity of the reaction is greatly decreased if halides or cyanides be present in considerable quantity. Pb, Cu, Sn, Cd, Ni and Co interfere if only traces of Hg are present. In the case of an organic compound the substance is boiled with hydrochloric acid and potassium chlorate, and pieces of zinc are placed in the solution for 24 hours. The zinc is treated with chlorine water and the test is applied to the liquid obtained.

Detection and Determination with Reinecke's Salt. Mercuric salts in N/10 hydrochloric acid solution gave a voluminous pale red precipitate with Reinecke's salt, $NH_4[Cr(NH_2)_2(SCN)_2]\cdot H_2O$. 2·5γ of the Hg can be detected in 5 ml. after 2 minutes standing. Only gold, silver and thallium compounds interfere. For the determination the solution should contain not more than 0·02 g. of Hg per 100 ml.; moderate amounts of nitric, sulphuric, acetic or tartaric acid do not interfere. The solution is acidified with hydrochloric acid until about N/2, heated nearly to boiling in a steam-bath in a covered beaker and treated, drop by drop, with a filtered, slightly acid solution of the reagent (0·05 g. per 0·01 g. of Hg). After standing a few minutes the precipitate is collected on a sintered glass crucible and well-washed with hot water. The subsequent determination may be carried out volumetrically or gravimetrically. In the volumetric process the precipitate is dissolved in the crucible by adding 0·2 to 0·3 g. of potassium cyanide and hot water, the filtrate and washings being collected in a 400 ml. flask, any chromium hydroxide that separates being dissolved in N/1 hydrochloric acid. Dilute the solution to 100 or 250 ml., add 3 to 7 ml. of strong sulphuric acid and 2 to 3 g. of potassium bromate, and boil for 15 minutes. Oxidation is promoted by the addition of 1 drop of nickel nitrate solution. Bromate is then destroyed by boiling for 20 minutes with 5 to 7 g. of ammonium sulphate and 5 to 6 ml. of N/1 hydrochloric acid; a current of CO_2 helps to remove bromine. Replace from time to time the water lost by evaporation. Cool, add 2 to 3 g. of potassium iodide and titrate with sodium thiosulphate. Each ml. of N/10 thiosulphate is equivalent to 0·0033495 g. of Hg. The gravimetric determination is effected by washing the precipitate with water and alcohol, drying for $1\frac{1}{2}$ hours at 105° to 110° and weighing; it contains 23·96% of Hg. If there is much precipitate it should be collected in a porous porcelain crucible or on filter paper and ignited to chromic oxide. 1 g. of Cr_2O_3 is equivalent to 1·3198 g. of Hg.—C. Mahr, *Z. anal. Chem.*, 1938, 241.

Determination in Organic Compounds. Based on Rupp's iodometric method a new procedure is described. The sample is decomposed by means of persulphate and sulphuric acid, bromide-bromate solution, potassium iodide and sodium hydroxide added and the mercury precipitated by hydrazine sulphate solution. Then sodium bicarbonate and magnesium sulphate are added to

produce magnesium carbonate to facilitate filtration, and the mercury filtered out. The mercury is then estimated by adding bromide-bromate solution, sulphuric acid and potassium iodide and titrating the iodine with sodium thio-sulphate. The method is applicable in the presence of halogens.—H. A. Sloviter *et al.*, *Industr. Engng Chem. (anal. Edn.)*, 1941, 890.

Hydrargyrum cum Creta (*B.P. Add. I*). Contains from 31 to 35% of mercury. Assayed by boiling with nitric acid and water, cooling, diluting, adding potassium permanganate solution to produce a permanent pink colour, decolorising with ferrous sulphate, and titrating with standard ammonium thiocyanate. Hydrargyrum cum Creta, *U.S.P. XII*, contains from 36 to 40% of Hg.

Mercury in a finely divided state is rapidly oxidised and a limit for mercuric mercury should have been included.—*Pharm. J.*, ii/1932, 106.

Pilula Hydrargyri (*B.P.*). Contains 32 to 34% of mercury.

Unguentum Hydrargyri (*B.P. Add. VI*). Assayed by boiling with nitric acid and water, filtering, adding potassium permanganate to a faint pink coloration, followed by decolorisation with ferrous sulphate and titration with N/10 ammonium thiocyanate; it should contain from 29 to 31% of mercury. The base now consists of a mixture of oleated mercury, wool fat, white beeswax and white soft paraffin. Unguentum Hydrargyri Dilutum, *B.P. Add. IV*, assayed similarly, contains 9.5 to 10.5% of Hg. Unguentum Hydrargyri Forte, *U.S.P. XII*, contains 47.5 to 52.5% of Hg, and Unguentum Hydrargyri Mite, *U.S.P. XII*, contains 9 to 11% of Hg; the Pommade Mercurielle, *Fr. Cx.* 1937, after washing with acidified alcohol-ether mixture leaves 50% of mercury. The dilute ointment contains 12.5%.

Unguentum Hydrargyri Nitratis Forte (*B.P.*). Contains not less than the equivalent of 6.7% of Hg. Assayed by digestion with sulphuric and nitric acids, precipitation as sulphide, finally drying at 110° and weighing.

Assay of Mercurial Ointments. The method recommended for the assay of mercury or one of its compounds in ointments, when it is distributed through, but not chemically combined with, the basis, consists of dissolving the basis in xylol in a centrifuge tube, and centrifugally separating out the suspended solid. Most of the liquid is now syphoned off, and the process repeated twice with fresh portions of solvent, replacing the xylol after the first time with light petroleum. A layer of alcohol is now interposed between the deposited solid and the petroleum layer. The mixture is centrifuged again, and the petroleum layer, along with some of the alcohol, drawn off. Either the residual alcohol is now evaporated off, the solid dissolved in nitric acid, transferred to a flask and titrated with ammonium thiocyanate, or the mixture is shaken, the alcoholic suspension rinsed into a flask, and the assay of the salt completed by the official or other suitable process.—W. R. Heading, *Quart. J. Pharm.*, 1934, 406.

The second report of the Commission Internationale des Spécialités includes an agreed method for the determination of mercury in ointments and plasters in which after separation from the base by means of a solvent the mercury compound is oxidised to the mercuric state with sulphuric and nitric acids and determined by precipitation as sulphide or titration with thiocyanate.—*Bull. Féd. int. Pharm.*, 1938, 56.

Method for Strong Ointment of Mercuric Nitrate. Heat the ointment with 50% aqueous potassium hydroxide for about 35 minutes in the presence of zinc dust. The mercury is set free first as mercuric oxide, which is then

reduced to metal by the hydrogen generated from the action of the alkali on the zinc. An amalgam is formed with the excess of zinc, and the mercury is thus obtained quantitatively in a granular form, which may easily be freed from soap by decantation, filtration and washing. The amalgam is next dissolved in nitric acid, and the mercury determined by means of ammonium thiocyanate, the presence of zinc as nitrate being quite without effect.—W. R. Heading, *Quart. J. Pharm.*, 1934, 413.

The official method may be modified with advantage by substituting titration with standard thiocyanate solution for gravimetric determination of the mercury as sulphide.

To about 5 g. in a long-necked flask of about 250 ml. capacity add 35 ml. of sulphuric acid, and heat cautiously until the mixture darkens. Add gradually 5 ml. of fuming nitric acid, rotating the flask to assist the escape of evolved gases. Heat, and maintain just below the boiling point. Repeat several times the addition of fuming nitric acid and the heating, until an almost colourless solution remains. Cool, add a slight excess of solution of potassium permanganate and heat to boiling. Add sufficient solution of hydrogen peroxide to make the solution colourless, cool and dilute to 250 ml. Titrate 100 ml. with N/10 ammonium thiocyanate, using solution of ferric ammonium sulphate as indicator.—C. H. Hampshire and G. R. Page, *Quart. J. Pharm.*, 1935, 75.

Methods involving digestion with sulphuric and nitric acids and saponification by aqueous potash give low results and the following method in which saponification is carried out with an aqueous-alcoholic solution is recommended.

To 2 g. of ointment in a 250 ml. conical flask add 10 g. potassium hydroxide pellets, 2 g. zinc dust, 10 ml. water and 10 to 20 ml. industrial methylated spirit, and boil for fifteen minutes over a small flame under a reflux condenser of the Liebig type, cautiously adding through the condenser a mixture of 3 ml. of formaldehyde solution and 50 ml. of water and then heat just to boiling and remove the flame. Filter off the hot soap solution through a paper pulp filter in a Gooch crucible, wash the amalgam with water by decantation, transfer the paper pulp to the flask and refit to the condenser. Pour through the condenser 20 ml. of water and then gradually 20 ml. of nitric acid, transferring any amalgam adhering to the crucible with a few drops of nitric acid. Heat the solution to remove the greater part of the nitrous fumes, cool thoroughly, oxidise with permanganate, decolorise with a drop of hydrogen peroxide and titrate with N/10 ammonium thiocyanate using iron alum as indicator.—*Quart. J. Pharm.*, 1933, 431.

The method of reducing the mercury compound to metal and amalgamating with zinc dust or filings is modified for oleated mercury, red mercuric iodide ointment, dilute ointment of mercuric nitrate and ointment of oleated mercury. The value of ethyleneglycol monoethylether as a menstruum for saponification in the assay of mercurial ointments containing paraffin is demonstrated.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1939, 413.

A tentative method for the assay of mercury in ointment of mercuric nitrate is described in *Methods of Analysis* (A.O.A.C., 1940, 622).

Unguentum Mercuriale (B.P.C.). Contains 33·3% of Unguentum Hydrargyri diluted with lard.

Hydrargyrum Ammoniatum (B.P.). NH_2HgCl = 252·1. Contains not less than 97% and not more than the equivalent of 100·5% of NH_2HgCl . Residue on ignition at a low red heat, not more than 0·2%. Assayed by treatment with potassium iodide and titration to methyl orange with N/10 hydrochloric acid. The U.S.P. XII substance is assayed for Hg content by precipitation as sulphide, and should contain HgNH_2Cl equivalent to from 78 to 80% of Hg.

Hydrargyrum præcipitatum album, P.G. VI, contains the equivalent of not less than 98·3% of NH_2HgCl . Hydrargyrum præcipitatum album, P. Helv. V, is assayed by the following process:—Mix 0·2 g. with about 50 ml. of water and 2 g. of sodium thiosulphate and shake frequently during 10 minutes until dissolved; add 2 or 3 drops of methyl orange and titrate with N/10

hydrochloric acid. 1 ml. of N/10 HCl is equivalent to 0.012604 g. of HgClNH_2 .

Assay of Ung. Hydrarg. Ammon. B.P. 1932. Weigh 3 g. of sample in a 250 ml. conical flask, add 25 ml. of xylol and gently warm to dissolve the base. Add 10 ml. of glacial acetic acid and 2 to 3 g. of potassium iodide dissolved in 10 ml. of water, using this solution to wash down the walls of the flask. Shake with a swirling motion for a few seconds until the aqueous solution is clear and pale brown in colour. Add 2 g. of zinc filings, reflux gently for fifteen minutes, wash down the condenser with 20 ml. of warm water and boil for a further five minutes. Remove the flame, allow to cool somewhat and add 150 ml. of water. Decant the xylol and aqueous solutions through a filter under slight suction. Wash the amalgam by decantation with xylol and water until the washings give no reaction for iodide. Dissolve the amalgam in dilute nitric acid, boil gently to remove nitrous fumes, cool, oxidise with permanganate, decolorise with a drop of solution of hydrogen peroxide and titrate with N/10 or N/20 ammonium thiocyanate. The method is also applicable to ointment of mercurous chloride, using 1 to 1.5 g. of sample, and to ointment of mercuric oxide, using 2 g. of a 10% ointment or 5 g. of a 1% ointment.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1941, 168.

Hydrargyrum Oleatum (B.P.). Should contain the equivalent of from 19 to 21% of yellow mercuric oxide. Assayed gravimetrically by precipitation as sulphide from a solution in benzene, glacial acetic acid and alcohol. Oleatum Hydrargyri, U.S.P. XII, contains the equivalent of 24 to 26% of HgO ; determined by the method for Massa Hydrargyri, by digestion in a Kjeldahl flask with sulphuric and nitric acids; after dilution potassium permanganate is added to the warm solution to produce a slight pink colour, this being discharged, after cooling, with oxalic acid, nitric acid added and titrating with N/10 ammonium thiocyanate. The preparation also contains a small amount of uncombined oleic acid.

Mercurochromum (B.P.C.). Loses on drying *in vacuo* at 50° over sulphuric acid, not more than 10% and then contains from 25 to 28% of Hg and from 21 to 23% of Br. Limit tests for free mercury, soluble mercury salts and sodium are described. Hg is estimated by separation as the zinc amalgam, which is then dissolved in nitric acid and treated with urea, the oxidised solution being titrated with N/10 ammonium thiocyanate; assayed for Br content by titration of the product of the fusion with potassium nitrate and potassium and sodium carbonates, with silver nitrate and ammonium thiocyanate. The B.P.C. '34 introduced a standard consisting of a quantity of mercurochrome kept by the Pharmaceutical Society and supplied on request. It is required that mercurochrome for intravenous injection shall be not more toxic than this standard sample. Manufacturers preparing mercurochrome are expected to determine the average lethal dose of the standard mercurochrome for mice in the conditions of their own laboratory. This dose, which kills 50% of mice, must be determined with care. Mice are then injected with the unknown sample, using the above determined dose. Ten mice are first injected, and if not more than two die, the sample passes the test. If more than two die, ten more are injected. If out of the twenty injected not more than eight die, the sample passes the test. If more than eight but less than fifteen die, ten more mice are

injected, and the sample passes the test if the number of deaths is not greater than fifteen out of the thirty mice injected. Merbrominum, *N.F. VII*, when dried at 110° , contains from 24 to 26.7% of Hg and from 18 to 21.3% Br. It is assayed gravimetrically for Br by fusion with anhydrous sodium carbonate, magnesium oxide and reduced iron followed by extraction with water and precipitation of silver bromide. Hg is determined by oxidation with potassium permanganate and sulphuric acid, decolorisation with oxalic acid and precipitation of mercuric sulphide.

Alkaline-Permanganate Oxidation Assay. The results obtained by the B.P.C. method for the assay of mercury show an appreciable experimental variation. The following alkaline-permanganate oxidation method appears to give more reliable and consistent results:—

Dissolve 0.5 g. of mercurochrome in 50 ml. of water in a 600 ml. beaker, add 10 ml. of 40% caustic soda solution and 2 to 3 g. of potassium permanganate, and boil gently over a micro-burner for 1 minutes. Cool slightly and add gradually a cooled mixture of 10 ml. of concentrated sulphuric acid and 200 ml. of water, avoiding loss by spurling by covering the beaker with a clock glass. Allow to cool, and add in small portions, with rapid stirring, a slight excess of 10 vols. hydrogen peroxide. Replace over the micro-burner, add excess of 5% potassium permanganate solution and ensure an excess after boiling gently for 10 minutes. Add dilute oxalic acid solution, drop by drop, until a water-white solution is obtained. Precipitation of the mercury as sulphide with subsequent filtration and weighing is carried out by the usual routine.—R. F. Corran and F. E. Rymill, *Quart. J. Pharm.*, 1935, 340.

Acid-Permanganate Oxidation, Assay.—*Methods of Analysis (A.O.A.C., 1940, 621).*

The mercury content may be rapidly determined by the following method. Half to 1 g. of mercurochrome is weighed out into a 250 ml. conical flask and dissolved in 20 ml. of water. 5 g. of caustic potash pellets and 2 g. of zinc filings are added and the mixture boiled under reflux condenser for at least 15 minutes. The flame is then removed and the condenser washed down with 50 ml. of water. The amalgam is filtered off by decantation, washed with water and dissolved in a mixture of 20 ml. of nitric acid and 20 ml. of water. After gently boiling off the nitrous fumes, the solution is cooled, treated with potassium permanganate, decolorised with a drop of hydrogen peroxide and titrated with N/10 ammonium thiocyanate. The results so obtained are in agreement with those given by the Codex method, and it is probable that both methods account for the whole of the mercury in the samples of mercurochrome assayed.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1940, 210.

Mersalylum (B.P. Add. I). $C_{13}H_{16}O_6NHgNa = 505.7$. Assayed for nitrogen by the Kjeldahl method, it contains 2.5 to 2.8% of N, and for mercury by digestion for 3 hours with water and hydrochloric acid, precipitation with hydrogen sulphide, washing the mercury sulphide on a Gooch crucible with hydrogen sulphide solution, alcohol and carbon disulphide and drying at 110° , it contains 38.5 to 40.5% of Hg, both calculated on the substance dried in a vacuum desiccator. Limit tests for mercuric salts and heavy metals, chloride, sulphate, and foreign organic matter are included. Mersalylum, *U.S.P. XII*, complies with the same standard for Hg. Loss on drying over sulphuric acid, not more than 7%.

HYDRASTIS

Hydrastis (B.P.C.). Foreign organic matter, not more than 2%. Acid-insoluble ash, not more than 3%. Hydrastis, *N.F. VII*,

should contain not more than 4% of foreign organic matter; it should yield not less than 2.5% of ether-soluble alkaloids of Hydrastis and not more than 3% of acid-insoluble ash. It is assayed gravimetrically by maceration with ether, shaking an aliquot part with acid and transferring the alkaloids to ether, finally drying at 100°. Rhizoma Hydrastis, *P.G. VI*, yields not less than 2.5% of hydrastine; assayed by maceration with ether and ammonia, addition of petroleum ether and water, filtration and evaporation of an aliquot part of the filtrate, finally dissolving in excess N/10 hydrochloric acid and titrating with N/10 potassium hydroxide to methyl orange indicator. Rhizoma Hydrastis, *P. Helv. V*, should also contain 2.5% of hydrastine by a process similar to the *N.F. VII* assay, using dilute hydrochloric acid for the extraction and ether and petroleum ether for the final extraction, and drying the hydrastine for 1 hour at 103° to 105°.

Since 1927 the highest yield of total alkaloids has steadily declined. In 1927 the highest yield of total alkaloids was 3.12% and the lowest 3.02% (by the *U.S.P. X* method). In 1936 the corresponding figures were 2.59 and 1.74% respectively. The *B.P.C.* (for the extract), *U.S.P. X* and *N.F. VI* methods of assay give different results. Two samples, giving respectively 2.73 and 1.74% by the *U.S.P. X* method, gave 2.56 and 1.34% by the *B.P.C.* method.—W. A. N. Markwell, *Chem. & Drugg.*, i/1937, 90.

Extractum Hydrastis Liquidum (*B.P.C.*). Assayed by addition of diluted potassium iodide solution and extraction with ether of an aliquot part of the filtrate rendered ammoniacal, finally drying the residual alkaloid on a water-bath; should yield 1.9 to 2.1% *w/v* of hydrastine. Fluidextractum Hydrastis, *N.F. VII*, contains 2.25 to 2.75% *w/v* of ether-soluble alkaloids of hydrastis; determined by extraction of total alkaloid with ether from ammoniacal mixture, transferring to acid and back to ether, and drying the final alkaloids at 100°.

Extractum Hydrastis (*B.P.C.*). Contains 7.5 to 8.5% of hydrastine. Extractum Hydrastis, *N.F. VII*, contains 9 to 11% of ether-soluble alkaloids.

Hydrastinae Hydrochloridum (*B.P.C.*). $C_{21}H_{21}O_6N, HCl = 419.6$. Loss at 100°, not more than 6%. Ash, not more than 0.1%. Limit tests for hydrastinine and berberine are included. The *N.F. VII* also includes these tests, and limits the moisture to 2% on drying over sulphuric acid.

Hydrastinine Hydrochloridum (*B.P.C.*). $C_{11}H_{12}O_2NCl = 223.5$. Ash, not more than 0.1%. Tests for limit of foreign alkaloids and hydrastine are described.

HYDROGENII PEROXIDUM

Liquor Hydrogenii Peroxidi (*B.P.*). Contains 2.5 to 3.5% *w/v* of H_2O_2 , corresponding to about ten times its volume of available oxygen. Residue on evaporation on a water-bath, not more than 0.2% *w/v*. Complies with limit tests for barium and acidity. Assayed by titration with potassium permanganate.

Liquor Hydrogenii Dioxidii, *U.S.P. XII*, contains 2·5 to 3·5% *w/v* of H_2O_2 .

P.G. VI gives method of estimation by titrating iodine liberated from potassium iodide.

HYOSCYAMUS

Hyoscyamus (B.P.). Contains not less than 0·05% of the alkaloids of hyoscyamus, calculated as hyoscyamine, not more than 2% of foreign organic matter and not more than 1% of stems more than 5 mm. in diameter. Ash limit, 20%. Acid-insoluble ash limit, 12%. Assayed by the process of the *B.P. Add. I*.—Hyoscyamus is macerated and percolated with ether-alcohol (4 : 1) with the addition of ammonia, the percolate extracted with N/2 hydrochloric acid and alcohol (4 : 1); the mixed acid liquids are cleaned with chloroform, made ammoniacal and the alkaloid, extracted as quickly as possible with chloroform, finally dried at 80° for 2 hours to remove volatile bases and titrated to methyl red or cochineal. Hyoscyamus, *U.S.P. XII*, is assayed either by maceration with ammonia solution, alcohol and ether, and continuous extraction with ether, or by maceration with ammonia solution, ether and chloroform, and percolation with ether-chloroform; either extractive is evaporated to low bulk, adding N/10 sulphuric acid and water towards the end of the evaporation and the acid liquids made ammoniacal and extracted with chloroform; the final alkaloidal residue is heated for 15 minutes on a water-bath, dissolved in chloroform, again heated and this operation repeated a third time; not less than 0·04% of alkaloids should be present. It contains not more than 25% of its stems, none being more than 7 mm. in diameter; acid-insoluble ash, not more than 12%.

Folia Hyoscyami, P.G. VI, yields not less than 0·07% of hyoscyamine. *Folium Hyoscyami, P. Helv. V*, consists of the leaves of the flowering plant of *Hyoscyamus niger* Linn., without stem, fruits or flowers, and contains not less than 0·05% of alkaloid. It may yield up to 20% of total ash and up to 6% of acid-insoluble ash. *Herba Hyoscyami mutici, P. Helv. V*, from *Hyoscyamus muticus* Linn., contains not less than 0·8% of alkaloids and is used for making extract and tincture of hyoscyamus.

The root is richest in total alkaloids and the annual plant is, if anything a trifle richer than the biennial leaves either of the first or second year: thus, biennial root, 0·16%; leaves, biennial first year, 0·059 to 0·069%; leaves and tops, second year, 0·065 to 0·068%; leaves and tops, annual, 0·064 to 0·07%.—S. Jensen, *Pharm. J.*, i/1915, 98.

Extractum Hyoscyami Liquidum (B.P.). Contains 0·045 to 0·055% *w/v* of alkaloids of Hyoscyamus.

Extractum Hyoscyami Siccum (B.P.). Contains 0·27 to 0·33% of alkaloids of Hyoscyamus. Extractum Hyoscyami, *U.S.P. XII* yields 0·135 to 0·175% of alkaloids.

Tinctura Hyoscyami (B.P.). Contains 0·0045 to 0·0055% *w/v* of alkaloids of Hyoscyamus, calculated as hyoscyamine. Tinctura

Hyoscyami, *U.S.P. XII*, contains 0.0034 to 0.0046% *w/v* of alkaloids.

Hyoscinae Hydrobromidum (B.P.). $C_{17}H_{21}O_4N \cdot HBr \cdot 3H_2O = 438.1$. M.p., after drying at 100° , 194° to 196° . Specific rotation determined in 5% *w/v* aqueous solution of the anhydrous salt, -24° to -26° . Loss at 100° , 12 to 13%. Ash, not more than 0.1%. Scopolaminae Hydrobromidum, *U.S.P. XII*, loses not more than 13% at 100° ; tests for apoeptropine and for morphine are included.

Tabellae Scopolaminae Hydrobromidi (N.F. VII). Tablets of 1.2 mg. or more contain 91 to 109%, and tablets of less than 1.2 mg. contain 88 to 112%, of the labelled amount of scopolamine hydrobromide, including all tolerances. Assayed by extracting with chloroform from an ammoniacal solution, adding 10 ml. of alcohol for each 50 ml. of chloroform to the combined chloroformic extracts, evaporating and dissolving the residue in alcohol and N/20 sulphuric acid, finally back titrating with N/50 sodium hydroxide using methyl red indicator.

Hyoscyaminae Hydrobromidum (B.P.C.). $C_{17}H_{23}O_3N \cdot HBr = 370.1$. Loss at 100° , not more than 1%. Ash, not more than 0.1%.

Hyoscyaminae Sulphas (B.P.C.). $(C_{17}H_{23}O_3N)_2 \cdot H_2SO_4 = 676.5$. M.p., not below 203° . Loss at 100° , not more than 1%. Ash, not more than 0.1%.

ICHTHAMMOL

Ichthammol (B.P.). The dried substance contains not less than 10.5% *w/v* of organically combined sulphur, and not more sulphur in the form of sulphates than one-fourth of the total sulphur. Loss at 100° , not more than 50% by weight. Residue on ignition and re-ignition with sulphuric acid, not more than 0.3%. Assayed for total sulphur by gentle ignition with sodium carbonate and copper nitrate, dispersion of the ichthammol in the sodium carbonate having been effected by evaporation with chloroform, followed by precipitation as barium compound and ignition: assayed for sulphates by precipitation of a solution with cupric chloride solution, filtration and precipitation with barium chloride; organically combined sulphur is obtained by the difference between these two percentages. Ichthammol, *N.F. VII*, by distillation with sodium hydroxide, yields not less than 2.5% of ammonia; by precipitation of the sulphate as barium salt from an alcohol and alcohol-ether extractive it yields not more than 8% of ammonium sulphate; by oxidation with potassium chlorate and nitric acid and final precipitation as barium sulphate, not less than 10% of total sulphur should be indicated.

Ichthyolsulfonate d'Ammonium, *Fr. Cx. 1937*, contains 8 to 12% of total sulphur, determined by ignition with sodium carbonate and potassium nitrate and precipitation as barium sulphate; sulphur as ammonium sulphate should be 1.25 to 1.50%, determined by treatment of an aqueous solution with egg white and hydrochloric acid and precipitation of the cold filtrate with barium salt. Ammonium sulfobituminosum, *P. Helv. V*, contains

1.2 to 4.2% of total ammonia, not more than 1.7% of sulphur as sulphate, and not less than 7.25% of total sulphur. The difference between the percentage of total sulphur and the sum of the sulphur as sulphate and the sulphur as sulphonie sulphur, gives the percentage of organically combined sulphur, which should not be less than 4%. Total ammonia is determined by distillation with magnesia into excess standard acid; ammonium sulphate is determined by precipitation of a solution of 3 g. of the substance in about 250 ml. of water with 20 ml. of a white of egg solution and 3 portions of 10 ml. of dilute hydrochloric acid, adjusting to 500 ml., filtration and precipitation of an aliquot part with barium chloride; total sulphur is determined by digestion with nitric acid and potassium chlorate during 3 to 4 hours and until reduced to low bulk, evaporation with hydrochloric acid and precipitation of barium sulphate.

INSULINUM

Insulinum (*B.P. Add. I and VI*). Complies with tests for sterility, and the solution contains 20 units per millilitre. Controlled by regulations of the Therapeutic Substances Act, 1925. The unit is the specific activity contained in such an amount of the standard preparation as the Medical Research Council may indicate as the quantity exactly equivalent to the unit accepted for international use. Crystalline insulin contains approximately 24,000 units per gramme. The label on the container or packet must state the date of manufacture and the date after which the preparation should not be used. The solution should be stored at as low a temperature as possible above the freezing-point and not exposed to a temperature above 20°. Insuline, *Fr. Cx.* 1937, should not contain more than 12 g. of nitrogen for 100 g. insulin containing 15 units per mg. Complies with tests for amino-acids and inactive proteins. *Injectio Insulini, U.S.P. XII*, is standardised to contain in 1 ml. 20, 40, 80 or 100 U.S.P. Insulin Units. The label on the container states the number of units per ml. and the expiration date which is not more than 2 years after the date of supply by the manufacturer.

Biological Methods of Assay

Rabbit Method. The rabbit method described in the *B.P.* depends on the observation that a dose of about 1 unit of insulin injected under the skin of a fasting rabbit causes a fall in the blood sugar which is greatest after 2 to 3 hours, the concentration returning to the normal value after 5 hours. If the initial percentage of blood sugar is observed, and also the percentage at the end of each hour for 5 hours after injection, a figure for the hypoglycæmic effect can be calculated. This is done by taking the average figure for the 5 hours after injection, and subtracting it from the initial figure. The result is then expressed as a percentage

of the initial figure and is called the percentage blood sugar reduction.

In performing the test, twelve rabbits of about 2 kg. weight, which have been without food for 24 hours, are used. Six are injected with 1 unit of the standard preparation, and six with a quantity of the unknown sample expected to contain 1 unit. The percentage blood sugar reduction is then determined for each rabbit. Two days later, the experiment is repeated on the same animals; the rabbits which before received the standard now receive the unknown, and those which received the unknown now receive the standard. There are now two figures available for each rabbit, namely the percentage blood sugar reductions when injected with the standard and those when injected with the unknown. The average figure given by all the rabbits for the percentage blood sugar reduction after injection with the standard is then compared with that after injection with the unknown preparation. If the dose of the unknown preparation was correctly chosen the two figures should be equal. If they differ appreciably the experiment must be repeated, using a different dose of the unknown.

Mouse Method. The mouse method depends on the appearance of convulsions in mice after they are injected with insulin. A large group of mice is taken, of which one half receives a dose of the unknown preparation, the other half receiving the standard. The percentage of mice in each group in which convulsions occur is then determined, and, from the result, the potency of the unknown can be stated in terms of that of the standard.

The mice are prepared by being kept without food overnight. They are injected and placed immediately in a thermostat kept at a temperature which is usually 29° or 34° . Symptoms, which may be those of collapse or of convulsions, occur within 2 hours, and the proportion of mice showing symptoms is determined. In deciding the potency of the unknown preparation in relation to that of the standard, two doses of the standard are used, one of which causes a higher percentage of convulsions than that caused by the unknown, while the other causes a lower percentage. The dose of the unknown can then be equated to the mean of the two doses of the standard. Alternatively, the relative potency of unknown and standard can be determined from the percentages of convulsions by using a previously determined curve relating dose to percentage convulsions.

A modification of the mouse method for the assay of insulin is described, enabling several unknown preparations to be assayed in a single test. Corrections for use in the simple method of calculation are described, so as to conform more closely with statistical theory. The question of weighting is discussed. —H. P. Marks, *Quart. J. Pharm.*, 1940, 344.

IODUM

Iodum (B.P.). $I=126.9$. By titration with N/10 sodium thiosulphate, it contains not less than 99.5% of I. Residue on volatilisation on a water-bath, not more than 0.05%. A standard of 99.8% of I is required by the *U.S.P. XII*.

Manufacture. The sea-weeds vary enormously in iodine content, and only *L. digitata* ("Tangle Stem") and *L. stenophylla* are worth burning for kelp. The varieties known collectively as *drift kelp* are richer than cut kelp. If properly burnt, the drift weed ought to yield 25 to 30 lb. of iodine per ton. 12 lb. per ton is, however, above the average for ordinary drift kelp. Very good Scotch kelp yields potassium sulphate 14%, potassium chloride 18%, sodium chloride 14%, sodium carbonate 4%, and iodine $14\frac{1}{2}$ lb. per ton. When burnt into "loose ash" these figures are respectively 13%, 18%, 6.8%, 3.4% and 28 lb.

The mineral known as **caliche**, the crude sodium nitrate of Peru and Chili, forms now by far the most important source of iodine. It is present in the form of iodate. Sodium bisulphite is used to precipitate the iodine from the mother liquors from which the sodium nitrate has been crystallised.

Oleum Iodisatum (*B.P. Add. I*). An iodine addition product of poppy-seed oil (stored in previously sterilised containers sealed to exclude bacteria), containing 39 to 41% of combined iodine. Determined by refluxing with glacial acetic acid and zinc powder for 1 hour, diluting and filtering; the cooled filtrate after addition of hydrochloric acid and potassium cyanide solution is titrated with M/20 potassium iodate, using starch mucilage as indicator. A limit of chloro-iodine compounds is included—sodium iodide is added to a solution in acetone and allowed to stand in the dark for 30 minutes with occasional shaking, the mixture then diluted and titrated with N/10 sodium thiosulphate. Free iodine in a solution in chloroform shaken with a potassium iodide solution is titrated with standard sodium thiosulphate. Complies with limit tests for acidity and mercury and with tests for sterility. **Oleum Iodatum**, *U.S.P. XII*, contains 38 to 42% of organically combined iodine, as shown by titration with M/20 potassium iodate of the filtrate obtained by igniting with sodium carbonate, extracting with water, acidifying and adding an equal volume of hydrochloric acid; forms a clear solution with 10 volumes of petroleum ether; ash, not more than 0.1%.

Chlorinated Iodised Oil. By the following process one molecule of iodine and one molecule of chlorine in an adjacent position are introduced into the unsaturated linkage of the fatty acids of the oil. The chlorine stabilises the iodine combination. 1000 g. of oil (vegetable or animal) is mixed with 2000 ml. of denatured alcohol, a few drops of phenolphthalein solution and sufficient N/2 sodium hydroxide to give a pink colour. The alcohol is siphoned off, 2000 ml. of water added and the mixture well stirred. The water is removed and the oil washed with a further 2000 ml. of water. A solution of iodine monochloride is prepared by adding with vigorous stirring in one rapid stream 720 ml. of hydrochloric acid to a solution of 357 g. of potassium iodide and 239 g. of potassium iodate in 720 ml. of water. Stirring is continued until the iodine monochloride first precipitated redissolves. A solution of the purified oil in ether (or other solvent) is gradually added to the iodine monochloride solution with constant stirring, the temperature being maintained at 20°–25°. The iodine monochloride is faintly yellow or almost white after completion of the reaction. The mixture is allowed to stand, the upper aqueous layer removed, 500 ml. of ethylene dichloride added, and the mixture is washed with running tap water until all hydrochloric acid is removed. The ethylene dichloride solution is separated from the water as completely as possible, treated with 750 ml. of dehydrated alcohol and rendered just alkaline to phenolphthalein by adding 4% alcoholic sodium hydroxide. The mixture is allowed to stand, the alcohol removed, the oil well washed, dried over anhydrous sodium sulphate, treated with activated charcoal and filtered, and the solvent removed by evaporation *in vacuo* at first without heat to remove ether, then at 55° for 6–8 hours to remove ethylene dichloride. Stability can be increased by adding $\frac{1}{2}$ –1% of purified non-iodised oil to absorb any free iodine liberated.—F. R. Greenbaum, *Amer. J. Pharm.*, 1937, 407.

Liquor Iodi Aquosus (*B.P.C.*). Prepared to contain 5% *w/v* of iodine and 7.5% *w/v* of potassium iodide. **Liquor Iodi Aquosus**, *B.P. Add. I*, contains 4.9 to 5.1% of iodine and 9.8 to 10.2% of potassium iodide. **Liquor Iodi Fortis**, *U.S.P. XII*, contains 4.5 to 5.5% *w/v* of I, and 9.5 to 10.5% *w/v* of KI. Assayed for iodine by titration with N/10 potassium arsenite. Hydrochloric

acid is then added to the titration mixture and potassium iodide determined by titration with M/20 potassium iodate, correction being made for the iodine present by calculation from the first titration.

Determination of Free and Combined Iodine in Solution. The following method avoids the necessity for shaking in a stoppered bottle and has the advantage that both free and combined iodine are determined on the sample. The iodide is titrated with iodate in the presence of potassium cyanide and hydrochloric acid using starch, the iodine cyanide formed is subsequently decomposed by adding potassium iodide, and the liberated iodine is titrated with N/10 sodium thiosulphate. If a ml. of potassium iodate are required, and b ml. of N/10 thiosulphate, the weight of combined iodine is equal to $0.0031725 (5a-2b)$ g. and that of free iodine is equal to $0.006345 (2b-3a)$ g. The process is applicable to each of the four pharmacopœial iodine solutions. For aqueous solution of iodine the formula should

be modified by multiplying by the factor $\frac{166}{126.9}$.—C. Morton and F. R. C.

Bateson, *Quart. J. Pharm.*, 1937, 498.

Liquor Iodi Decoloratus. No evidence of the presence of iodate could be found. Iodoform was found in fresh samples but not in older ones. It was not possible to demonstrate the presence of a formate.—C. Morton and F. R. C. Bateson, *Quart. J. Pharm.*, 1937, 500.

Liquor Iodi Fortis (B.P.). Contains from 9.8 to 10.2% w/v of iodine and 5.8 to 6.2% of potassium iodide. Iodine content estimated by titration with N/10 sodium thiosulphate, and potassium iodate in presence of 40% of hydrochloric acid, and subtracting one half the thiosulphate titration. Alcohol content, 76 to 79% v/v of ethyl alcohol, decolorising with sodium thiosulphate and adding sodium hydroxide before distillation. *Tinctura Iodi, U.S.P. XII*, contains 6.8 to 7.5% w/v of I and 4.7 to 5.5% w/v of KI; alcohol content 83 to 88% v/v . Assayed for iodine by titration with potassium arsenite and for potassium iodide by titration with M/20 potassium iodate. *Tinctura Iodi Fortior, N.F. VII*, contains 16 to 17% w/v of I and 3 to 4% w/v of KI.

Liquor Iodi Mitis (B.P.). Iodine content, 2.45 to 2.55% w/v ; potassium iodide content, 1.45 to 1.55% w/v . Alcohol content, 85 to 88% v/v of ethyl alcohol. *Tinctura Iodi Mitis, U.S.P. XII*, contains 1.8 to 2.2% w/v of I and 2.1 to 2.6% w/v of NaI. *Liquor Iodi, U.S.P. XII*, is an aqueous solution of the same strengths.

Liquor Iodi Simplex (B.P.). Simple solution of iodine is prepared with 9% w/v of iodine in alcohol (95%). Owing to rapid reduction of the iodine it is standardised to contain from 8.8 to 9.2% w/v of total iodine.

When simple solution of iodine is stored the content of free iodine becomes constant in 8 months. The acidity of the solution still increases slightly after the free iodine content has become constant. A solution assaying 8.78% w/v of free iodine 7 days after preparation reached equilibrium at 7.17% of free iodine after storage for 8 months.—G. R. Page, *Quart. J. Pharm.*, 1935, 81.

Unguentum Iodi Denigrescens (B.P.C.). Prepared with arachis oil and yellow soft paraffin to contain 5% w/w of iodine. *Unguentum Iodi, B.P.C.* '34, contains 4% of iodine with potassium iodide and water in simple ointment.

Unguentum Iodi, U.S.P. XII, is assayed for total iodine content (6.5 to 7.5%) by ignition with potassium carbonate, extraction with water, oxidation with permanganate and just decolorising with alcohol, addition of potassium iodide and sulphuric acid to an aliquot part of the filtered liquid, and titration with sodium thiosulphate.

Assay. The following method for the determination of iodine in iodised oils may be used for the assay of iodine in non-staining iodine ointments:—About 1 g. of the sample, accurately weighed, is boiled for one hour under a reflux condenser with 10 ml. of glacial acetic acid and 1 g. of zinc filings. 30 ml. of hot water is added down the condenser tube, the liquid is filtered through a plug of wet cotton wool, and the flask and filter are washed with two portions of 20 ml. of water. The combined filtrate and washings (the filtrate need not be clear) are cooled, 100 ml. of hydrochloric acid is added, and the liquid titrated with M/20 potassium iodate, chloroform being added as indicator towards the end of titration, and titration being continued until, after vigorous shaking, the chloroform is colourless, the aqueous liquid being clear yellow. Each millilitre of M/20 potassium iodate is equivalent to 0.01269 g. of I.—T. T. Cocking and G. Middleton, *Quart. J. Pharm.*, 1931, 176.

The free and combined iodine in stainless or ordinary iodine ointments may be determined by distilling 2 g. of the sample with a little powdered pumice and 100 ml. of strong sulphuric acid in a 400 ml. distilling flask connected to an air condenser and a bulb-tube dipping under 50 ml. of water. Boil gently for 3 to 4 hours, rinse the condenser and tube with water, filter the distillate and washings to remove organic matter which distils over, acidify with nitric acid and precipitate with silver nitrate. Boil, collect, wash, dry and weigh.—F. W. Edwards, E. B. Parkes and H. R. Nanji, *Analyst*, 1935, 748.

A tentative method for the determination of free iodine in iodine ointment is described in *Methods of Analysis (A.O.A.C., 1940, 619)*.

DETERMINATION OF IODINE IN BIOLOGICAL SUBSTANCES

Report of the Medical Research Council: C. O. Harvey, *Spec. Rep. Ser. med. Res. Coun., Lond.*, 1935, No. 201.

Numerous methods have been published which give satisfactory results in the hands of their authors but erratic results when tried elsewhere. In the following method, based on Hurlley's modification of von Fellenberg's process, all possible sources of error have been considered and each detail of procedure rigidly standardised. The original report must be consulted for details of the processes and the preparation of the reagents.

MILK. 40 to 50 ml. of sample is mixed with 4 ml. of 10N potassium hydroxide and set aside for 5 to 6 days in a covered 350 ml. flask stirring occasionally. The mixture is heated on a steam-bath in a glass beaker until homogeneous and then evaporated nearly to dryness on a steam-bath in a nickel dish (free from copper), surface scum being removed after 1 to 2 hours by means of a glass rod which is rinsed and removed. The residue is heated in an oven at 150° to 160° for 1 hour, and then on an electrically heated sand-bath at 400° to 420° for 2 hours, the swollen mass being frequently pierced with a glass rod. It is finally carbonised in an electric muffle at 480° to 500° for 1 hour. The cooled mass is moistened with 20 ml. of water, warmed, filtered through a washed filter (Whatman No. 30), and the residue washed until the total filtrate measures 40 ml. The filter paper is moistened with water in the nickel dish, 0.1 ml. of 10N potassium hydroxide added, the whole stirred thoroughly, and then evaporated to dryness, dried at 150° to 160° for 15 minutes and ignited in the muffle at 480° to 500° for 1 hour. The residue is extracted as before, and the combined filtrates evaporated to dryness, heated in the oven for ½ to 1 hour and then in the muffle for 5 minutes. The product is dissolved in a little water and the evaporation and ignition repeated. The alkaline mass thus obtained is dissolved in 25 ml. of water, digested on a steam-bath, filtered, and the filter washed 2 or 3 times with 3 ml. quantities of N/10 potassium carbonate. The filtrate is evaporated to dryness in a recently ignited porcelain dish, the residue dried for 30 minutes at 150° to 160° and then ignited in the muffle at 480° to 500° for 5 minutes. The alkaline mass is rubbed to a smooth cream with sufficient water (about 2 ml.) to produce almost complete solution (previous to trituration the moistened mass is allowed to stand overnight), 5 ml. of dehydrated alcohol added, followed by two further portions, each of 5 ml., the mass being well rubbed up between each addition and again after all the alcohol has been added until the potassium carbonate

passes into a pasty condition. The alcohol layer is decanted into a recently ignited platinum dish and the residue is re-extracted twice with 5 ml. of dehydrated alcohol, small quantities of water being added if necessary to maintain the pasty condition. The combined alcoholic extracts are treated with 0.15 ml. of N/1 potassium carbonate, and the alcohol is rapidly evaporated by heating the dish on a steam-bath in a current of nitrogen under a cover to prevent ingress of dust, complete removal of the alcohol being effected by heating at 150° to 160° for 5 minutes. The residue is treated with 0.5 ml. of 0.8% potassium nitrate solution and 1 to 2 ml. of water, and rapidly evaporated on the steam-bath, dust being excluded. The residue is dried for 5 minutes at 150° to 160°, then heated in the muffle for 2 minutes only. The product obtained should now be entirely free from carbonaceous matter. It is dissolved in 0.5 ml. of 1% sodium azide and 2 ml. of water, the solution is transferred completely to a titration flask, using 2 quantities, each of 1 ml., of water for rinsing purposes, N/2 sulphuric acid is added until the reaction is acid to methyl orange (as indicated by spotting minute drops on to methyl orange paper), 0.05 ml. more being added than is required for neutrality, and then 0.20 ml. of saturated bromine water. A glass bead is quickly added and the bromine boiled off by means of a micro burner, the flask being agitated gently, until the volume is reduced to about 2 ml. (2½ to 3 minutes) as indicated by a mark etched on the flask. The liquid is then cooled rapidly in water, 0.1 ml. of N/2 sulphuric acid, 0.1 ml. of starch solution and 0.1 ml. of potassium iodide are added, and the mixture titrated with N/500 sodium thiosulphate. Frequent blank determinations must be carried out on a 20% aqueous solution of iodine-free sucrose in order to correct for traces of iodine that may be present in reagents, filter papers or the atmosphere of the laboratory. A correction is applied for differences in the volume of the solution after the bromine boiling process. The weight of iodine found is increased by 0.06 ($V-v$) gamma, where V is the volume after titration in the actual determination, and v the volume in the blank determination.

VEGETABLE MATERIALS. 3 to 5 g. of dry powdered material is mixed with 3 ml. of 10N potassium hydroxide and 30 to 40 ml. of water and heated on a steam-bath for 2 to 3 hours. The process is continued as described above.

BLOOD. 10 ml. of sample is mixed with 20 ml. of water and 1.5 ml. of 10N potassium hydroxide and heated on a steam-bath for 2 to 3 hours. The process is continued as described above. The mass must be repeatedly pierced while being heated on the sand-bath and in the muffle.

OILS AND FATS. Fatty materials including milk powders must be saponified with alcoholic potash before ignition.

DRINKING WATER. 2 to 5 litres of sample is mixed with 4 ml. of 10N potassium carbonate and evaporated in a nickel dish. When nearly dry, 2 ml. of 20% iodine-free sucrose solution is added, and the mixture dried in the oven at 150° to 160°, then heated in the muffle at 480° to 500° for 1 hour. The residue is completely extracted with hot water, and the filtrate treated as described for milk. If much nitrate is present a greater quantity of azide may be required.

MATERIALS CONTAINING SULPHUR. A little iodine-free hydrogen peroxide is added just before the last evaporation in the nickel dish.

FISH PRODUCTS. Ashing is conducted in the presence of iodine-free sucrose to prevent formation of iodate.

SALINE MATERIALS. After the first alcoholic extraction it may be necessary to dissolve the product in water and re-extract with alcohol.

Reagents.

DISTILLED WATER. Re-distilled after being rendered strongly alkaline with potassium hydroxide.

DEHYDRATED ALCOHOL. Dehydrated alcohol is refluxed for 20 minutes over 1% of solid potassium hydroxide. It is then re-distilled in an all-glass apparatus, the first 10 to 20% being rejected and the distillation stopped when 10 to 20% of the original bulk remains. The product has a sp. gr. of not greater than 0.800 and is stored in the dark.

POTASSIUM CARBONATE. Iodine is removed by the following process. 500 g. is dissolved completely in hot water (about 300 ml.) and 0.25 g. of hydrazine sulphate dissolved in a little water is added. The mixture is evaporated in a porcelain dish until it forms a stiff pasty mass on cooling. It is extracted 4 to 5 times with iodine-free alcohol (95 to 96% v/v) using about 200 ml. for each extraction. The residue is dissolved in water, the solution evaporated and the

extraction repeated. Excess of alcohol is removed by suction, and the residue is dried at 150° and ignited in a muffle furnace at 500° for several hours.

20% SUCROSE SOLUTION. The sucrose is freed from iodine by dissolving in the minimum quantity of hot water, adding 10N iodine-free potassium hydroxide (about 2 ml. per 100 g. of sucrose), boiling until partial caramelisation takes place and precipitating with dehydrated alcohol. The sucrose is filtered off and redissolved and reprecipitated several times.

SATURATED BROMINE WATER. This is largely freed from hydrobromic acid by repeatedly washing the bromine with water before preparing the reagent. It is stored in amber-coloured bottles in the dark.

2% POTASSIUM IODIDE SOLUTION. Prepared with recently boiled water. It must be tested at frequent intervals for iodate and free iodine by carrying out a blank test containing 0.1 ml. of N/2 sulphuric acid, 0.1 ml. of the 2% potassium iodide solution and 0.1 ml. of soluble starch solution.

0.5% SOLUBLE STARCH SOLUTION. Soluble starch is prepared as follows:—50 g. of arrowroot starch is mixed with 250 ml. of 2N hydrochloric acid and the mixture allowed to stand for several days at room temperature with occasional stirring. The acid is then decanted and the residue well washed with water by decantation until free from acid and dried on filter paper.

N/500 SODIUM THIOSULPHATE. Prepared with boiled water containing 1% of pure amyl alcohol. It is stored away from direct daylight in a container provided with a soda lime tube and an all-glass siphon. It should be re-standardised at least once a week, using either N/100 potassium bi-iodate or N/500 sulphuric acid with potassium iodide-iodate solution.

C.I.S. Method.

The Second Report of the Commission Internationale des Spécialités includes an agreed method for the determination of iodine in organic substances in which the iodine is converted to iodide by fusion with either potassium hydroxide or a mixture of alkali carbonate and nitrate. The iodide in acid solution is converted to iodate by means of hypochlorite and the free iodine liberated on adding potassium iodide is titrated with sodium thiosulphate.—*Bull. Fed. int. Pharm.*, 1938, 25.

Iodoxylym (B.P. Add. III). $C_8H_5O_5NI_2Na = 493$. Loses on drying in a vacuum desiccator, not more than 1% and then contains 50.5 to 52.5% of I and 9.2 to 9.4% of Na. Assayed for iodine by the method of the *B.P. Add. I* for Thyroxinsodium, and for sodium by ignition and re-ignition with sulphuric acid.

Liquor Diodoni (B.P.C. Supp. III). Determined by the *B.P. Add. I* method for Thyroxinsodium, contains 17.3 to 17.7% w/w of I, corresponding to 34.7 to 35.5% w/w of the diethanolamine salt. Sp. gr., 1.191 to 1.196. Residue, dried at 100° , 35.2 to 35.9%. pH, 6.0 to 8.0.

IPECACUANHA

Ipecacuanha (B.P. Add. III and VI). Contains not less than 2% of the total alkaloids of ipecacuanha, calculated as emetine, of which not less than 55% consists of non-phenolic alkaloids, calculated as emetine and contains not more than 1% of foreign organic matter. Ash, not more than 5%; acid-insoluble ash not more than 2%. Assayed for total alkaloids by maceration and percolation with ether-chloroform (3:1), transferring to acid solution, first with N/1 sulphuric acid and then with portions of N/10 acid and alcohol (3:1), finally extracting with chloroform from ammoniacal solution, determining the alkaloids by titration using methyl red or cochineal indicator; assayed for

non-phenolic alkaloids by extraction of the titration liquid, made alkaline with sodium hydroxide, with ether and, after evaporation, titration of the alkaloids. *Ipecacuanha*, *U.S.P. XII*, should contain not less than 2% of ether-soluble alkaloids of *ipecacuanha*, not more than 5% of its overground stems, or more than 2% of other foreign organic matter. Assayed by maceration with peroxide-free ether and extraction of an aliquot part, using ether for the final extraction of the alkaloids from ammoniacal solution.

Radix Ipecacuanhæ, *P.G. VI*, yields not less than 1.99% of alkaloid, calculated as emetine. *Radix Ipecacuanhæ*, *P. Helv. V*, contains not less than 2% of alkaloid soluble in ether. *Assay*: Shake frequently and vigorously 3 g. of the root in powder with 60 g. of ether and 2.5 ml. of dilute ammonia, for 30 minutes. Pour the supernatant ethereal liquid through cotton wool, evaporate off the ether completely and repeat with a second portion of 5 ml. of ether. Dissolve the residue in 1 ml. of alcohol, add 5 ml. of N/10 hydrochloric acid, 10 drops of methyl red and heat on a water-bath for one minute; dilute with 20 ml. of recently boiled and cooled water and titrate the excess of acid with N/10 sodium hydroxide: each millilitre of N/10 HCl is equivalent to 0.0238 g. of ether-soluble alkaloid.

Paul and Cownley stated the average composition of Rio and Carthagena alkaloids to be: emetine in Rio 72%, in Carthagena 40.5%; cephaeline in Rio 25.9%, Carthagena 56.8%. See also H. R. Jensen, *Pharm. J.*, i/1916, 519.

In the initial maceration of the *B.P.* assay process the powdered drug should be shaken with the ether-chloroform mixture for at least 15 minutes, otherwise percolation to complete extraction is very prolonged.—P. A. W. Self, *Pharm. J.*, i/1933, 244.

Of 37 samples, only 7 failed to comply with *B.P. 1932* requirements for alkaloids. The average content of total alkaloids was 2.31%, and of non-phenolic alkaloids calculated as emetine, was 1.59%.—C. E. Corfield, *Quart. J. Pharm.*, 1934, 603.

***Ipecacuanha Pulverata* (*B.P. Add. VI*).** Adjusted to contain 1.9 to 2.1% of total alkaloids of *ipecacuanha*, calculated as emetine, not less than 55% being non-phenolic alkaloids, calculated as emetine. Ash, not more than 5%; acid-insoluble ash not more than 2%.

***Extractum Ipecacuanhæ Liquidum* (*B.P.*).** Contains 1.9 to 2.1% of total alkaloids of *ipecacuanha*, calculated as emetine. Assayed by extraction of an acid liquid, made ammoniacal, with chloroform, evaporation and titration of the alkaloid. Alcohol content, 75 to 80% *v/v* of ethyl alcohol. *Fluidextractum Ipecacuanhæ*, *U.S.P. XII*, by a maceration process with peroxide-free ether, transference of the alkaloid from an aliquot part to N/1 sulphuric acid with final extraction from ammoniacal solution with peroxide-free ether, and titration of the alkaloid, yields 1.8 to 2.2% *w/v* of ether-soluble alkaloids of *ipecacuanha*.

Tentative methods for the determination of total alkaloids in fluidextract of *ipecacuanha* are described in *Methods of Analysis* (*A.O.A.C.*, 1940, 598).

***Tinctura Ipecacuanhæ* (*B.P.*).** Contains 0.095 to 0.105% *w/v* of total alkaloids of *ipecacuanha*, calculated as emetine. Alcohol content, 20 to 24% *v/v* of ethyl alcohol. Assayed by

cleansing of an acid mixture with chloroform, followed by ammoniacal chloroform extraction. *Tinctura Ipecacuanhæ, N.F. VII*, yields 0.18 to 0.22% *w/v* of ether-soluble alkaloids of ipecacuanha. *Tinctura Ipecacuanhæ I.A.* contains 0.2% of total alkaloids and is prepared with 70% alcohol.

Emetina (B.P.C.). $C_{29}H_{40}O_4N_2 = 480.3$. Loss on drying in a vacuum at atmospheric temperature, not more than 1%. Ash, not more than 0.1%. Complies with the limit test for cephaeline.

Emetinæ Hydrochloridum (B.P.). $C_{29}H_{40}O_4N_2 \cdot 2HCl \cdot 7H_2O = 679.4$. Loss at 100° , 15 to 19%. Ash, not more than 0.1%. By extracting emetine with chloroform, from a solution made alkaline with sodium hydroxide, acidifying the aqueous liquid, adding ammonia, extracting with chloroform and drying at 100° , a limit of cephaeline equivalent to not more than 2% of the alkaloid is included. *Emetinæ Hydrochloridum, U.S.P. XII*, should lose 8 to 14% at 100° . The same limit of cephaeline, but extracted with ether, is allowed. 0.1 g. in 5 ml. of sulphuric acid conforms with a test for carbonisable substances.

An official method for the determination of emetine hydrochloride in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 584)*. The emetine, extracted with ether from alkaline solution, is dissolved in alcohol and titrated with standard acid, using methyl red indicator.

A colorimetric method for the determination of emetine in hypodermic tablets and injections is described. The method depends upon the orange colour produced by the action of hydrogen peroxide on emetine in the presence of hydrochloric acid and can only be used to detect gross errors. Tables are given correlating the value of the yellow component of the colour obtained and the emetine content.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 244.

Emetinæ et Bismuthi Iodidum (B.P.). Contains 25 to 28% of emetine, $C_{29}H_{40}O_4N_2$, and 18 to 21% of Bi. Loss at 100° , not more than 2%. Assayed for emetine by titration, with N/10 sulphuric acid, of the alkaloid extracted with chloroform from an acid mixture made ammoniacal; and for bismuth by precipitation with ammonium phosphate from the ammoniacal liquids just neutralised with hydrochloric acid, finally weighing the ignited residue.

JALAPA

Jalapæ (B.P.). Should contain not more than 2% of foreign organic matter, and not less than 9% of resin. Assayed by the *B.P.* method by continuous extraction of 20 g. with 90% alcohol, evaporation of the solvent, washing the residue with four quantities of 10 ml. of hot water, and drying at 100° . *Jalapæ, N.F. VII*, should yield not less than 9% of total resins of jalap; assayed by the *N.F. VII* method for *Ipomœa*; acid-insoluble ash, not more than 0.5%. Brazilian jalap, which contains a much higher percentage of a similar resin, is not included in the *B.P.*

Tubera Jalapæ, P.G. VI, contains not less than 10% of resin. *Tuber Jalapæ, P. Helv. V*, contains not less than 10% of resin which should yield not more than 3% to ether.

The following test for purity is recommended by the Sub-Committee on the Assay of Galenicals of the Committee on Pharmaceutical Chemistry:—Weigh 0.5 g. of the residue obtained in the assay, finely powdered, in a tared dry 100-ml. flask, add 25 ml. of anæsthetic ether, shake vigorously for fifteen minutes, and allow to stand overnight; pour off the ether solution into a dry flask, wash the residue with 10 ml. of anæsthetic ether, and dry at 100°; the weight of the residue is not less than 0.425 g. (limit of ether-soluble resins).—(*British Pharmacopœia Commission Report*, No. 11, May 1939.)

Jalapæ Pulverata (B.P.). Adjusted with powdered exhausted jalap or with lactose to contain 9 to 11% of resin.

Jalapæ Resina (B.P.C.). The dried substance contains not less than 85% of ether-insoluble resins. Loss at 100°, not more than 5%. Ash, not more than 0.5%. Water-soluble matter, not more than 2%. Assayed by shaking vigorously with 50 parts of freshly distilled ether, standing and evaporating, and drying at 100° the decanted ether and washings. Resina Jalapæ, *N.F. VII*, should yield not more than 32% of chloroform-soluble matter, dried at 100°, and not more than 12% of ether-soluble resins; loss at 100°, not more than 4%, Résine de Jalap, *Fr. Cx.* 1937, yields not more than 3% insoluble in chloroform and not more than 12% insoluble in ether; acid value 26 to 28; saponification value, 234 to 244. Resina Jalapæ, *P. Helv. V*, yields not more than 3% to ether, when 1 g. in powder is shaken frequently during 6 hours with 10 g. of ether.

Ipomœa (B.P.). Ipomœa or Orizaba jalap root (Mexican scammony root) is the dried root of *Ipomœa orizabensis* (Pellet.) Levanos. The resin extracted with 90% alcohol and washed has the properties of Scammonizæ Resina.

Ipomœa, *N.F. VII*, yields not less than 15% of total resins; acid-insoluble ash, not more than 3%. Assayed by digestion on a steam-bath for 30 minutes and percolation with alcohol and water (9 : 1), extraction of an aliquot part with chloroform and hydrochloric acid (1%) and chloroform and alcohol (2 : 1), finally drying the residue from the evaporated chloroform alcohol at 100°.

Scammonizæ Resina (B.P.). Loss at 100°, not more than 5%. Ash, not more than 0.5%. Water-soluble matter, not more than 1%. Contains not more than 40% of ether-insoluble resins, and the ether-soluble resins have an acid value not exceeding 30. Resina Ipomœæ, *N.F. VII*, leaves not more than 0.5% of ash, and loses not more than 4% at 100°; alcohol-insoluble residue, not more than 0.5%.

Résine de Scammonée, *Fr. Cx.* 1937, has an acid value of 15 to 33, saponification value of 180 to 185; α_D of 4% solution in alcohol (95%), decolorised with charcoal, -16° to -24° , allowing for weight of resin soluble. Résine de Scammonée du Mexique leaves not more than 40% insoluble in ether; acid value, 14 to 28; saponification value, 180 to 229.

Radix Scammonizæ, *P. Helv. V*, is described as the dry root of *Convolvulus Scammonia* L., containing not less than 18% of resin; neither scammony nor ipomœa resin is official. Scammonée d'Alep, *Fr. Cx.* 1937, on mixing with an equal weight of sand, shaking during 12 hours and washing with ether, yields not less than 60% of resin.

Resins from convolvulaceous drugs may be identified by shaking 0.05 g. of powdered resin with acetone 5 ml., filtering, placing 2 ml. of the filtrate and 10 ml. of hydrochloric acid in a test-tube and immersing in a boiling water-bath for ten to fifteen minutes, when a purplish-red colour forms, turning magenta on dilution with one or two volumes of water. Positive reactions were obtained with jalap and scammony and with 2 ml. of a 10% acetone tincture of jalap tuber, ipomœa root and turpeth root.—E. J. Schorn, *Pharm. J.*, i/1941, 206.

LIGAMENTA

Ligamentum Crispi (B.P.C.). Crêpe bandage when fully extended should measure not less than twice the length of the

unstretched bandage; after being fully extended for one minute, it returns to not more than two-thirds the fully extended length. Contains not less than 33.3% of wool, all in the warp. A 3-inch bandage contains in the warp not less than 47 cotton threads and 94 wool threads with 2 two-fold binding threads at each edge. There are one two-fold cotton thread (right twist), 2 wool threads, one two-fold cotton thread (reverse twist), 2 wool threads, in the warp threads. Count of the wool, not coarser than 25's and not finer than 30's (worsted count). The warp threads are made of two-fold cotton yarn with a finished count, after doubling, not finer than two-fold 20's and containing not fewer than 54 folded turns per inch. Weft should consist of 20's count cotton threads, numbering not less than 25 per inch when fully stretched. Weight of 3 inch wide fully stretched bandage, not less than 617 grains per 5 yards.

Ligamentum Domettæ (B.P.C.). Domette bandage contains not less than 66.6% of wool. Foreign matter, not more than 2%; weight of 2 inch by 6 yards bandage, not less than 440 gr. Minimum average number of threads per inch, 40 in the warp and 22 in the weft, and the total number per sq. inch, 65.

Ligamentum Elasticum Adhesivum (B.P.C.). A fully stretched elastic adhesive bandage of 3 inches by 5 yards contains not less than 2 oz. of rubber adhesive compound, and after removal of this and other foreign matter, and correcting for natural moisture regain, weighs not less than 1.75 oz. When released the fully stretched bandage returns to not more than 80% of its length. Warp threads not less than 44 per inch and made of two-fold cotton yarn with a finished count, after doubling, not finer than two-fold 26's and containing not fewer than 44 folded turns per inch, and woven 2 ends right twist and 2 ends reverse twist. Weft threads not less than 20 per inch when fully stretched, and of cotton yarn not finer than 8.5's.

Ligamentum Lanulæ (B.P.C.). Flannel bandage must contain not more than 3% of foreign matter. Weight, not less than 900 gr. per 2 inches by 6 yards. Minimum average threads per inch, 26 in the warp and 28 in the weft.

Ligamentum Linæ (B.P.C.). Bleached calico bandage contains not more than 1.5% of foreign matter. Weight, not less than 210 gr. per 2 inches by 4 yards. Minimum average threads per inch, 67 in the warp and 58 in the weft.

Ligamentum Linæ Crudæ (B.P.C.). Unbleached calico bandage contains not more than 10% of foreign matter. Weight, not less than 250 gr. per 2 inches by 4 yards. Minimum average threads per inch, 65 in the warp and 60 in the weft.

Ligamentum Pastæ Zinci (B.P.C.). The warp of zinc paste bandage should be of cotton yarn of a count not finer than 40's and not heavier than 30's, and from 30 to 35 threads per inch; the weft, of cotton yarn, 26's to 16's and 20 to 25 threads per inch.

Ligamentum Sindonis (B.P.C.). Muslin bandage contains not more than 1.5% of foreign matter. Weight per 2.5 inches by 6 yards, not less than 190 gr. Minimum average threads per inch, 48 in the warp and 30 in the weft.

Ligamentum Textum Apertum (B.P.C.). Open-weave bandage contains not more than 1.5% of foreign matter. Weight per 2 inches by 4 yards, not less than 200 gr. Minimum average threads per inch, 43 in the warp and 27 in the weft. Bleached count of the warp yarn, 40's to 33's.

LINUM

Linum (B.P.). Should contain not more than 2% of foreign organic matter. *Linum, U.S.P. XII*, contains not more than 2%

of other seeds or foreign organic matter. Non-volatile ether-soluble extractive, not less than 30%. Unsaponifiable matter of the non-volatile ether-soluble extractive, not more than 2%.

Linum Contusum (B.P.). Ash not more than 5%. Should yield not less than 30% of fixed oil having the characters and properties of *Oleum Lini*, B.P. '32, when continuously extracted with ether.

Ispaghula (B.P.C.). Foreign organic matter, not more than 3%. Weight of 100 seeds, 0.17 g. to 0.22 g. Agitated in a 25 ml. stoppered cylinder with 20 ml. of water occasionally during 24 hours and allowed to stand for one hour, 1 g. occupies not less than 10 ml.

Psyllium (B.P.C.). Foreign organic matter, not more than 3%. Weight of 100 seeds, 0.09 g. to 0.13 g. 1 g. agitated with water, as described under Ispaghula, occupies not less than 12 ml. *Plantaginis Semen*, N.F. VII, may be obtained from *Plantago ovata* Forskal, and from *P. Psyllium* Linné and *P. arenaria* Waldstein et Kitaibel; foreign organic matter, not more than 0.5%; ash, not more than 4%; acid-insoluble ash, not more than 1%; 1 g. of seed with water to 20 ml. shaken during 24 hours and stood during 12 hours occupies not less than 14 ml. for *P. Psyllium*, not less than 10 ml. for *P. ovata*, and not less than 8 ml. for *P. arenaria*.

Ispaghula and Psyllium of Commerce. All the seeds present in commercial samples of ispaghula examined are seeds of *P. ovata*. Seed of *P. amplexicaulis* appears to be unobtainable commercially. Commercial samples of "Psyllium" seed sometimes consist of seeds of either *P. arenaria* or *P. lanceolata*, partly or wholly. "Bartung" or "Barhang" consists of seeds of *P. major*. It does not occur as an article of commerce in European countries although used widely in the East.—E. W. Skyrme, *Quart. J. Pharm.*, 1935, 11.

A tabular summary of the microscopical characters of the seeds of psyllium, ispaghula and three other species of *Plantago*.—E. W. Skyrme and T. E. Wallis, *Quart. J. Pharm.*, 1936, 198.

LITHIUM

Lithii Acetylsalicylas (B.P.C.). $\text{CH}_3\text{CO}\cdot\text{OC}_6\text{H}_4\cdot\text{COOLi}$ = 186.0. The lithium is assayed as Li_2SO_4 and should be equivalent to not less than 95% of pure acetylsalicylate.

Lithii Benzoas (B.P.C.). $\text{C}_6\text{H}_5\cdot\text{COOLi}$ = 128.0. Contains not less than 98.5% and is assayed by the B.P. process for sodium benzoate. Lithii Benzoas, N.F. VII, determined on the salt dried at 100°, by titration in ethereal solution with N/2 hydrochloric acid to methyl orange indicator, contains 98.5% of the pure substance; loss at 100°, not more than 3%. Benzoate de Lithium, Fr. Cx. 1937, assayed by titration with N/10 hydrochloric acid to helianthine, removing the liberated benzoic acid with ether, should contain 99%, on the dried substance, and by weight of the extracted benzoic acid should contain not less than 94.41% of benzoic acid.

Lithii Bromidum (B.P.C.). LiBr = 86.86. By titration with excess of silver nitrate and ammonium thiocyanate the dried salt

contains 98% of LiBr. Loss at 160°, not more than 15%. Tests for limit of bromate and iodide are included. Lithii Bromidum, *N.F. VII*, contains 85 to 90% of the anhydrous salt; a limit of "other alkalis," by weighing the chlorides insoluble in amyl alcohol, is included.

Lithii Carbonas (*B.P.C.*). $\text{Li}_2\text{CO}_3=73.88$. Assayed by titration with excess acid and sodium hydroxide, a purity of not less than 98.5% on the dried substance should be indicated. Loss at 100°, not more than 1%. Lithii Carbonas, *N.F. VII*, after drying to constant weight at 100°, contains not less than 99% of Li_2CO_3 ; leaves not more than 0.15% of residue insoluble in dilute acetic acid; a limit of "other alkalis," by weight of the chlorides insoluble in amyl alcohol is included; loss at 100°, not more than 2%.

Lithii Chloridum (*B.P.C.*). $\text{LiCl}=42.40$. Loses, on drying at 100°, not more than 5% of its weight and then contains 99% of LiCl by titration of the chloride.

Lithii Citras (*B.P.C.*). $\text{C}_6\text{H}_5\text{O}_7\text{Li}_3, 4\text{H}_2\text{O}=281.9$. Should contain 98.5% of the pure salt; the assay by weighing the residue of Li_2SO_4 when ignited with sulphuric acid, replaces the *B.P.* '14 estimation of the alkalinity of the ash. The *N.F. VII* salt, determined by titration of the ash with standard sulphuric acid, contains not less than 98.5% of $\text{C}_6\text{H}_5\text{O}_7\text{Li}_3$ after drying at 165°. Loss at 165°, not more than 26%. A test for other alkalis is included—the residue obtained by ignition with hydrochloric acid is extracted with water, the residue on evaporation of this water extract is boiled with amyl alcohol and hydrochloric acid and the insoluble matter dried at 110°.

Lithii Iodidum (*B.P.C.*). $\text{LiI}=133.9$. Loses not more than 10% at 120° and the dried salt contains 99% of LiI. The iodide may be estimated by titration with standard potassium iodate.

Lithii Salicylas (*B.P.C. Supp. IV*). $\text{C}_7\text{H}_5\text{O}_3\text{Li}=144.0$. Dried at 130° it contains not less than 98.5% of $\text{C}_7\text{H}_5\text{O}_3\text{Li}$. Loses not more than 3% of its weight at 130°. Assayed by the *B.P.* method for Sodii Salicylas: about 3 g. dissolved in 50 ml. of water, with 50 ml. of ether and a little bromophenol blue indicator are shaken and titrated with N/2 sulphuric acid until a colour change takes place; the titration of the separated aqueous layer, a 10 ml. water washing of the ethereal layer and a fresh 20 ml. of ether is completed, with constant shaking. Lithii Salicylas, *N.F. VII*, dried to constant weight at 100°, contains not less than 98.5% of $\text{LiC}_7\text{H}_5\text{O}_3$. Determined by titration, in ethereal mixture, with N/2 hydrochloric acid to bromophenol blue indicator, separating the ether and continuing the titration of the aqueous portion after addition of more ether. Salicylate de Lithium, *Fr. Cx.* 1937, assayed similarly to the *B.P.C.* method, contains not less than 99% corresponding to 94.93% of salicylic acid; the salicylic acid content is determined by weight of the precipitate produced with iodine in alkaline solution.

LOBELIA

Lobelia (B.P.). Contains not more than 60% of stems and not more than 2% of foreign organic matter. Acid-insoluble ash, not more than 5%. Lobelia, *N.F. VII*, should contain not more than 10% of stems and 4% of other foreign organic matter, and should leave not more than 5% of acid-insoluble ash. *Herba Lobeliae, P. Helv. V*, when assayed by the process prescribed, yields not less than 0.3% of alkaloids; ash, not more than 13%.

Assay. Introduce 10 g. of the lobelia in No. 60 powder and 10 g. of ignited sand into a pear-shaped separating funnel provided with a plug of cotton wool in the tube below the stopcock. Add 75 ml. of a mixture of 4 vols. of ether and 1 vol. of 95% alcohol (by volume). Shake and set aside for 15 minutes, add 5 ml. of dilute ammonia (10% of NH_3), and shake in a mechanical shaker for 1 hour or by hand for 1 minute at 10-minute intervals during one hour. Allow the liquid to percolate into another separating funnel. When the liquid ceases to flow, pack the drug firmly by means of a button-ended glass rod. Continue the percolation, first with 25 ml. of the ether-alcohol mixture and then with ether, until the alkaloid is completely extracted, as shown by testing in the usual manner. To the percolate add 30 ml. of N sulphuric acid. Shake well and allow to separate. Run off the lower layer into another separator. Repeat the extraction with a mixture of 25 ml. of 0.5 N sulphuric acid with 5 ml. of alcohol (95%). Run off the lower layer and repeat with three further quantities of 20 ml. of the acid-alcohol mixture or until the alkaloids are completely extracted. Wash the mixed acid solutions, first with 10 ml. and then with successive quantities of 5 ml. of chloroform, washing each chloroform solution with the same 20 ml. of 0.5 N sulphuric acid contained in another separator. Reject the chloroform, transfer the acid liquid from the second separator to the first separator, neutralise to litmus with dilute ammonia solution and add a further 5 ml. in excess. Extract the alkaloids by shaking with successive quantities of 10 ml. of chloroform. Combine the chloroform solutions and wash with 3 ml. of distilled water. Filter the chloroform solution through a 7-cm. filter paper into a flask. Wash the filter thoroughly with more chloroform and collect the washings in the flask. Distil the chloroform from a water-bath until about 2 ml. remain. Add 2 ml. of absolute alcohol and continue the evaporation on the water-bath, using a gentle air-blast to complete the process. Repeat with two further lots of absolute alcohol to ensure dehydration of the residue. Heat the residue for 1 hour at 80°. Add to the residue 2 ml. of alcohol (95%) and warm until dissolved. Add 10 ml. of 0.02 N sulphuric acid. Cool and titrate with 0.02 N sodium hydroxide or sodium borate solution, using methyl red as indicator. One ml. of 0.02 N sulphuric acid is equivalent to 0.00674 g. of the alkaloids of lobelia calculated as lobeline.—per *Analyst*, 1939, 581.

Hydrochloric acid cannot replace sulphuric acid in the assay because lobeline hydrochloride is extracted from aqueous solution by chloroform. Thorough dehydration of the alkaloidal extractive before heating it is necessary to avoid hydrolysis and production of acetophenone.—W. A. N. Markwell, *Pharm. J.*, i/1936, 617.

Assays of lobelia and its preparations are examined, and recommended processes are described for the drug and tinctures.—H. A. Caulkin, *Quart. J. Pharm.*, 1939, 438.

Lobélie Enflée, Fr. Cx. 1937, contains not less than 0.375% of total alkaloids:—Moisten the equivalent of 12.5 g. of drug dried at 100° with 40 g. ammoniacal alcohol (90% with 10% ammonia solution), after 3 hours add 360 g. ether and shake frequently during 3 to 4 hours; filter and reduce by distillation the solvent from 320 g. (10 g. powder) to 10 g.; transfer to a separator with 3 portions of 150 ml. of ether and shake with 15 ml. N/1 hydrochloric acid, completely extract with further quantities of 5 ml. (test with silico-tungstic acid). Allow the ether to evaporate from the mixed acid liquids, add 10 ml. of silico-tungstic acid solution (5%) and after 12 hours, collect the precipitate, wash with N/1 hydrochloric acid until the washings do not precipitate quinine hydrochloride solution (1%) and ignite. 1 g. residue = 0.415 g. total alkaloids.

Lobelinum hydrochloridum, $C_{21}H_{27}O_2N.HCl$, is official in the *P.G. VI*. Lobelinum hydrochloricum, *P. Helv. V*, dried over sulphuric acid, contains not more than 1% of moisture; 0.4 g. in 20 ml. of water at 20° in a 200 mm. tube has an optical rotation of -2.23° to -2.33° ; the separated alkaloid, after drying over sulphuric acid for 24 hours, melts at a temperature not below 116° . Titration with sodium hydroxide to phenolphthalein should show not less than 99.3% of $C_{21}H_{27}O_2N.HCl$.

MAGNESIUM

Magnesii Carbonas Levis (B.P.). Residue on ignition, 42 to 45%; calcium limit, 2% as CaO. Magnesii Carbonas, *U.S.P. XII*, by titration with excess of N/1 sulphuric acid and N/1 sodium hydroxide to methyl orange, contains the equivalent of 40 to 43.5% of MgO; a calcium limit equivalent to not more than 0.6% of CaO is included. Magnesii Carbonas Ponderosus, *B.P.*, leaves a residue on ignition of 42 to 45% and has a limit of 0.7% of CaO. Magnesium subcarbonicum, *P. Helv. V*, yields on ignition from 39.0 to 44.1% of residue and the residue contains not less than 99% of MgO.

Liquor Magnesii Bicarbonatis (B.P.). Should contain not less than 2.5% *w/v* of $Mg(HCO_3)_2$. Assayed by titration of total alkalinity to methyl orange with subtraction of the alkali limit titration obtained by boiling the ignited residue with water, filtering and titrating.

Magnesii Hydroxidum (B.P.C.). $Mg(OH)_2 = 58.34$. Residue on ignition, 67 to 70%.

Mistura Magnesii Hydroxidi (B.P.). Contains the equivalent of 7.75 to 8.75% *w/v* of $Mg(OH)_2$. Magma Magnesiae, *U.S.P. XII*, contains 7 to 8.5% of $Mg(OH)_2$. It may contain 0.1% citric acid. In the test for heavy metals, 5 ml. is dissolved in 6 ml. of dilute hydrochloric acid and the solution evaporated to dryness. The residue is dissolved in 20 ml. of distilled water, 2 ml. of dilute acetic acid added and the test completed in the usual manner.

Magnesii Oxidum Leve (B.P.). $MgO = 40.32$. Loss on ignition, not more than 5%; calcium limit, 5% as CaO. Magnesii Oxidum, *U.S.P. XII*, loses not more than 10% on ignition, and then contains not less than 96% MgO, by titration of alkalinity to methyl orange less the calcium determined as for the carbonate; CaO limit, 1.5%. Magnesii Oxidum Ponderosum, *B.P.*, loses not more than 5% on ignition and has a calcium limit of 1.75% of CaO. The *U.S.P. XII* substance loses not more than 10% on ignition, and then contains not less than 96% of MgO. Magnesium oxydatum, *P. Helv. V*, loses not more than 15% of its weight on ignition, and the ignited substance contains not less than 99% of MgO.

Magnesii Trisilicas (B.P. Add. IV and VI). Loses 20 to 30% on ignition at dull red heat and then contains magnesium equivalent to 30.0 to 31.5% of MgO and silicon equivalent to 66 to 69.5% of SiO_2 . Assayed for silicon by digestion with hydro-

chloric acid for 3 hours, heating at 105° for 2 hours, further digestion with hydrochloric acid, and water, and after separation of the silica and further recovery from the filtrate, ignition to constant weight and subtraction of the portion non-volatile with sulphuric and hydrofluoric acids; magnesium is precipitated from the filtrates as magnesium ammonium phosphate, finally weighing as pyrophosphate. A test for neutralising power to N/20 hydrochloric acid, when digested at 37° for 3 hours is included; the equivalent of 1 g. of the ignited substance neutralises not less than 250 ml. of N/20 acid. The *U.S.P. XII* substance contains not less than 20% of MgO, not less than 45% of SiO_2 and loses on ignition not more than 34%. The ratio of the percentage of SiO_2 to the percentage of MgO lies between 2.10 and 2.30. A test for adsorptive power using methylene blue solution and a limit test for heavy metals are included. 1 g. of the anhydrous substance when digested at 37° for 4 hours with occasional shaking, is equivalent to not less than 140 and not more than 160 ml. of N/10 hydrochloric acid.

Tabellæ Magnesii Trisilicatis (*U.S.P. XII*). Not less than 20 tablets, when reduced to a fine powder, completely pass through a 200 mesh sieve and comply with tests for free alkali, acid consuming capacity and adsorption of methylene blue. Tested for free alkali by boiling with water, filtering, cooling and titrating with N/10 hydrochloric acid, using phenolphthalein indicator. Acid consuming capacity determined by digestion of a weighed quantity of powdered tablets with N/10 hydrochloric acid at 37° with occasional shaking throughout 4 hours, the mixture being left undisturbed for the last 15 minutes, and finally titrating an aliquot of the supernatant liquid with N/10 sodium hydroxide using methyl orange indicator. The volume of N/10 acid consumed corresponds to 85 to 110 ml. per g. of magnesium trisilicate taken. Tested for adsorption of methylene blue by shaking a weighed quantity of powdered tablets with 0.1% aqueous methylene blue solution continuously for 5 minutes and then intermittently for 1 hour, filtering and comparing the colour of the filtrate with a specified dilution of the methylene blue solution.

Peroxyde de Magnésium, Fr. Cx. 1937, by titration with N/10 potassium permanganate contains not less than 25% of MgO_2 .

Magnesia Mixture. Solution of Magnesium Ammonio-Sulphate. Dissolve magnesium sulphate 20, ammonium chloride 40, in water 160, add ammonia solution 84. Allow to deposit in a stoppered bottle before use. Employed for the gravimetric determination of phosphates. Ammonium magnesium phosphate is precipitated and converted by incineration into magnesium pyrophosphate. $\text{Mg}_2\text{P}_2\text{O}_7$.

Detection of Magnesium. Magnesium may be detected by means of *o-p*-dihydroxyazo-*p*-nitrobenzene (*syn.* Magneson; *o-p*-dihydroxybenzeneazo-*p*-nitrobenzene; *p*-nitrobenzeneazoresorcinol), $\text{NO}_2\text{C}_6\text{H}_4\text{N}:\text{NC}_6\text{H}_3(\text{OH})_2$. The reagent is used as a 0.1% solution in 1% sodium hydroxide solution; it keeps for several months, but should not be used if more than a year old. The test solution is freed from other metallic radicles except the alkali metals by the ordinary group reactions. Ammonium compounds are then removed by evaporating to dryness and igniting. The residue is dissolved in 10 ml. of water acidified with hydrochloric acid, and 1 drop of the reagent is added followed by

10 ml. of sodium hydroxide solution. A blue colour or precipitate visible after about 5 minutes denotes the presence of Mg.

Determination of Magnesium. Magnesium can be determined by means of 8-hydroxyquinoline (*syn.* Oxine), $C_9H_7N.OH$. The reagent is used either as a 5% solution in alcohol or as a 2% solution in 2N acetic acid. The test solution, containing about 0.02 g. of magnesium in 50 ml., is made alkaline with ammonia, sufficient ammonium chloride being added to prevent precipitation, and heated nearly to the boiling-point. The alcoholic reagent solution is then added until the liquid becomes yellow in colour, when a compound of the composition, $Mg(C_8H_6ON)_2.4H_2O$, separates. The precipitate is collected, washed with hot faintly ammoniacal water and dried at 100° to 105° , at which temperature $2H_2O$ is lost. Each gramme of residue is equivalent to 0.0698 g. of Mg. Alternatively, the precipitate may be dissolved in 5N hydrochloric acid, and the filter washed with sufficient water to yield 2N acid. The solution is titrated to a yellow colour with N/5 bromine solution, using methyl red as indicator. Potassium iodide is added and the liberated iodine titrated with N/10 sodium thiosulphate. Each millilitre of N/5 bromine is equivalent to 0.000608 g. of Mg. Direct titration with N/5 bromine is impracticable because of the indefinite end-point. The procedure must be modified in the presence of an excess of an alkaline earth metal.

Magnesium forms with oxine a dihydrate, $Mg(C_8H_6ON)_2.2H_2O$, which is reasonably constant in weight at 110° after $2\frac{1}{2}$ hours, and at 98° after drying for a considerably longer period. Drying this precipitate in a steam-oven for 1 hour before weighing as the hydrate would, therefore, give rise to an appreciable error. It is possible in some instances that a small proportion of 8-hydroxyquinoline is precipitated with the oxinate, and that this is gradually volatilised during the drying process, at a rate dependent on temperature and time. The anhydrous magnesium complex is only obtained after heating the dihydrate at 160° . Hence the most reliable results from a gravimetric determination of magnesium as oxinate are likely to be obtained by drying the precipitate to the anhydrous form at 160° , and errors attributed to other causes may frequently be connected with inadequate drying.—R. C. Chirnside, C. F. Pritchard and H. P. Rooksby, *Analyst*, 1941, 399.

In the presence of ammonium citrate, manganese may be precipitated with oxine from a slightly acid solution containing magnesium without co-precipitation of the magnesium. Upon adding excess of ammonia to the filtrate, previously heated to 70° , and allowing to stand at room temperature for 2 hours complete precipitation of 0.01 g. of magnesium is effected. Solutions containing less than 0.01 g. of Mg should be allowed to stand overnight before filtration. 0.005 g. in 400 ml. of solution was completely precipitated by this means. If the concentration of Mg is smaller, the solution should be concentrated before precipitation. Free oxine in the precipitate may be removed by washing with a little warm alcohol, as well as with hot water. Calcium is co-precipitated only to a small extent in the presence of ammonium citrate, and may be removed as oxalate before precipitation of the magnesium-oxine complex. Alternatively the magnesium complex may be dissolved in dilute hydrochloric acid and reprecipitated. Phosphoric acid does not interfere with the precipitation of magnesium with oxine. The method has been used for the determination of Mg. in compound syrup of glycerophosphates.—G. J. W. Ferrey, *Quart. J. Pharm.*, 1942, 258.

MALTUM

Extractum Malti (*B.P. Add. V*). Determined by the Kjeldahl method, it contains nitrogen equivalent to not less than 4.5% w/w of protein. Sp. gr., 1.40 to 1.42. n_{D20° , 1.4892 to 1.4976. Extractum Malti, *U.S.P. XII*, should be capable of converting *not* less than five times its weight of dried starch into water-soluble sugars; assayed by testing for remaining starch, with N/10 iodine, the resultant solution from a digestion of purified potato starch (equivalent to 5 quantities of dried starch) at 40° for thirty minutes.

Extractum Malti cum Oleo Morrhuae (B.P.). Contains 10% *w/w*, equivalent approximately to 15% *v/v*, of cod-liver oil. For methods of determining the proportion of oil in malt and cod-liver oil, see the notes under *Oleum Morrhuae*.

For the determination of oil in *Extractum Malti cum Oleo Morrhuae*, see p. 286.

Extractum Malti cum Vitaminis (B.P.C.). Each fluid drachm contains approximately 3000 units of vitamin A and approximately 225 units of vitamin D.

Methods of Analysis for All-English Malt Extracts. S.R. & O., 1933, No. 540.

(a) Diastatic Activity (or Lintner Value)

SOLUBLE STARCH. Digest purified potato starch with dilute hydrochloric acid of sp. gr. 1.04 (in the proportion of 1 lb. of starch to 1 litre of dilute acid) at a temperature not exceeding 20° for 7 days, well shaking daily. Thoroughly wash the starch by decantation, first with tap water until washings react only faintly acid, then four times with distilled water. Weigh about 20 g. of the sludge, dissolve in 200 ml. of boiling distilled water and neutralise with N/10 sodium hydroxide solution, using 2 or 3 drops of alizarin cream as indicator. Add to remaining weighed starch sludge the calculated amount of sodium hydroxide solution just to neutralise its acidity, shake thoroughly and set aside for 12 hours. Wash by decantation three times with distilled water, collect the soluble starch on a paper in a Buchner funnel and drain by suction. Transfer to new unglazed porous plates and dry at moderate temperature (40° to 45°). When moisture content is reduced to about 15%, grind the soluble starch in a porcelain mortar and rub through a fine hair sieve.

SOLUBLE STARCH SOLUTION. Rub 20 g. of soluble starch into a cream with water and pour into about 700 ml. of boiling water. Bring to the boil, heat for a further 2 minutes, then cool to about 20°, shaking to prevent formation of skin. Add 20 ml. of acetate buffer solution (see below) and dilute to 1 litre with water. (10 ml. of this solution should not reduce 0.1 ml. of Fehling's solution). Fresh soluble starch solution should be made for each day's determination.

ACETATE BUFFER SOLUTION. One litre to contain 68 g. of sodium acetate ($\text{CH}_3\text{COONa} \cdot 3\text{H}_2\text{O}$) and 500 ml. of N/1 acetic acid.

MALT EXTRACT (SYRUP) SOLUTION. 5% solution. Weigh 10 g. of extract and break down with cold water. Heat must not be used to assist in weighing or bringing into solution. Transfer the solution to a 200 ml. graduated flask, dilute to the mark at 15° and shake well. Weaker solutions, also made up at 15°, are prepared from this. These solutions must not be filtered, and are used as soon as possible for starch conversion.

MALT EXTRACT (FLOUR SOLUTION). 5% solution. Weigh 10 g. of flour into a beaker, add 200 ml. of water at 15° and thoroughly stir. Cover and digest for 3 hours in a water-bath at 21°, stirring at intervals of half an hour. Three hours after, filter through filter paper. Reject the first 25 ml. of filtrate, and if the remainder of the filtrate is not quite bright re-filter. This solution, or weaker solutions prepared from it, is used as soon as possible for starch conversion.

METHOD OF STARCH CONVERSION. Measure 100 ml. of soluble starch solution into a 200 ml. graduated flask and immerse, suitably supported, in a water-bath maintained at 21°. Place a standardised thermometer in the flask, and when the contents have reached 21° add, by means of a narrow-bore pipette (N.P.L. standard), a definite volume (which should not normally exceed 10 ml.), measured at 15°, of the malt extract solution and mix well. (The volume needed will depend upon the diastatic activity of the extract and will be about

80

ml. of 5% solution or correspondingly larger
DIASTATIC ACTIVITY OF THE SAMPLE
volumes of 2½% or 1% solution.) Maintain the contents of the flask at 21° for exactly one hour. Then add 20 ml. of N/10 sodium hydroxide solution and mix immediately, care being taken to wash down the thermometer and also to allow

the alkali to flow over the inner surface of the neck of the flask. Cool the solution to 15°, dilute to 200 ml. with water and shake well. This solution is referred to in the method of titration as *the conversion solution*.

METHOD OF TITRATION. Measure into a 200 ml. round-bottomed flask 5 ml. of Fehling's solution (see later), and heat over a naked flame with continuous rotation of flask until solution boils. Run from a burette into the boiling liquid 5 ml. of the conversion solution, and subsequently further quantities. After each addition boil the liquid, the flask being continuously rotated. When the blue colour of the copper solution has nearly disappeared add 0.2 ml. of 1% aqueous solution of methylene blue. Continue the titration with small quantities of the conversion solution, drop by drop, until the blue colour just disappears. (Notes.—The indicator is not added until the end-point is nearly reached since the final change is very rapid. The complete decolorisation of the methylene blue is indicated by the whole reaction liquid, in which the precipitated cuprous oxide is continually being churned up, becoming bright red or orange in colour. To ensure that the end-point has been reached hold the flask against a sheet of white paper, and if the indicator is completely decolorised there will be no blue tint at the edge of the liquid. The boiling process must be sufficiently continuous to prevent air obtaining access to the flask and so causing oxidation of the indicator with reappearance of the blue colour.)

If the volume of the conversion solution used to reduce 5 ml. of Fehling's solution is less than 20 ml. or more than 25 ml., the conversion must be repeated, using less or greater quantities of the malt extract solution, to obtain a titration between these limits. If the extract solutions become aerated or subjected to warm conditions, re-weigh and carry out the dilutions again.

A first titration to obtain approximate results is to be followed by a second, and third if necessary, to establish the end-point accurately. A confirmatory titration should be carried out in every case.

FEHLING'S SOLUTION. Measure into a dry flask equal quantities of the solutions Nos. 1 and 2, and mix.

Solution No. 1. One litre to contain 69.28 g. of crystallised copper sulphate, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$.

Solution No. 2. One litre to contain 346 g. of Rochelle salt and 150 g. of sodium hydroxide.

Freshly mix for each day's determination.

Checked against 0.1% standard invert sugar solution by the method of titration described above, 5 ml. of Fehling's solution corresponds to 0.02533 g. of invert sugar.

Method of Calculating Diastatic Activity (Lintner Value). Express the result according to the following formulæ:—

(a) In the case of flour, diastatic activity (or Lintner value)

$$= \frac{1000}{X \times Y}$$

(b) In the case of syrup, diastatic activity (or Lintner value)

$$= \frac{1000}{X \times Y} \text{ minus } 9.$$

Where X = number of ml. of 5% malt extract solution in 100 ml. of the conversion solution.

Y = number of ml. of conversion solution required to reduce 5 ml. of Fehling's solution.

And 9 = a constant denoting the assumed equivalent of the reducing sugars present in the malt extract (syrup) used in making the determination.

The British Pharmacopoeia Commission Report, No. 11, May 1939, recommends the above method to be used as a limit test of diastatic value for extract of malt. 5 ml. of solution of potassium-cupric tartrate should require not more than 20 ml. of the conversion solution produced when 5 ml. of a 2% solution of extract of malt is treated in the foregoing manner.

(b) **FIBRE CONTENT.** Extract 2 to 3 g. with petroleum spirit, b.p., 40° to 60°, in an extraction apparatus, or at least three times by stirring, settling and decantation, and transfer the dry residue to a conical 1000 ml. flask. The material must not be further ground during extraction. A volume of 200 ml. of

a solution containing 1.25 g. of sulphuric acid (H_2SO_4) per 100 ml. measured at ordinary temperature and brought to boiling point is added and heated. The contents of the flask must boil within one minute and the boiling throughout must be gentle, and continuous for exactly 30 minutes, the original volume being maintained. Rotate the flask every few minutes. After 30 minutes remove the flask and pour contents into the shallow layer of hot water remaining in a funnel fitted with a pump-plate, or into the similar layer remaining in a Buchner funnel. Prepare the funnel by cutting a piece of cotton cloth or filter paper to cover the holes, so as to serve as a support for a disc of ordinary filter paper; pour boiling water into the funnel and allow to remain until funnel is hot, when suction is applied. Discard the experiment if the time of filtration of the bulk of the 200 ml. exceeds 10 minutes. Wash the residues with boiling water until the washings are free from acid. Then wash the residue from the filter paper back into the flask with a volume of 200 ml. of a solution of sodium hydroxide, containing 1.25 g. of sodium hydroxide ($NaOH$) per 100 ml., free from sodium carbonate, measured at ordinary temperature, and brought to boiling point. Boil the contents of the flask for exactly 30 minutes, the precautions given for the treatment with acid being observed. At the end of 30 minutes, remove the flask and filter its contents through an ordinary filter paper. Wash the residue collected in the filter paper with boiling water, then with solution of 1% hydrochloric acid and again with boiling water until free from acid. Wash the residue twice with 95% alcohol, and three times with ether. Transfer the residue to a dried weighed ashless filter paper, dried at about 100° in an oven and weighed in a weighing bottle until constant in weight. Determine the ash of the paper and contents by incineration at a dull red heat. Subtract the weight of ash from the increase of weight found on the paper and report the difference as fibre.

ASH CONTENT. Ascertain the ash content by heating a measured quantity of the substance in a muffle furnace at such a temperature that the ash does not fuse.

PROTEIN CONTENT. Ascertain the amount of soluble protein by multiplying the amount of nitrogen present (other than ammoniacal or nitric nitrogen, if any) by 6.25.

MALT EXTRACTS PRODUCED FROM BARLEY GROWN IN ENGLAND AND WALES: GRADE DESIGNATIONS AND DEFINITIONS

(S.R. & O., 1933, No. 540)

(a) *Pharmaceutical Malt Extract*

| Grade Designation | Definition of Quality † |
|--|--|
| All-English (Pharmaceutical) Malt Extract or alternatively* National Mark (Pharmaceutical) Malt Extract. | <p><i>General.</i> The Extract shall be prepared from sound, clean, malted grain by digestion with water at a suitable temperature and by evaporation of the strained liquid under reduced pressure at a temperature not exceeding 55° until an amber or yellowish-brown viscous product is obtained having the characteristic agreeable odour and sweet taste. The product shall be miscible with water in all proportions, forming a translucent solution.</p> <p><i>Special.</i> The protein content shall be not less than 4.5% of the total weight. The arsenic content shall not exceed 1.4 parts per million. The sp. gr. at 15.5° shall be from 1.40 to 1.42, and the refractive index at 20° from 1.4892 to 1.4976.</p> |

*The alternative "National Mark" may only be used in connection with pharmaceutical malt extract to which the grade designation mark as set out in the Fourth Schedule has been lawfully applied in accordance with the Agricultural Produce (Grading and Marking) (General) Regulations, 1928. (S.R. & O., 1928; No. 674.)

†Extract of Malt as defined in the *British Pharmacopœia*, 1932, would conform with these requirements.

(b) *Bakers' and Veterinary Malt Extracts*

| Grade Designation | Definition of Quality | |
|--|--|---|
| | Particular Characteristics | Common Characteristics |
| All-English (Bakers') Malt Extract (White Bread) | Diastatic activity shall be not less than 40 Lintner value | <i>General.</i> The product in each case shall be the water-soluble extract derived from commercially sound, clean malted grain. |
| All-English (Bakers') Malt Extract (Brown Bread) | None | <i>Special.</i> The specific gravity at 15.50° shall be not less than 1.4 and the soluble protein-content not less than 4.5% of the total weight. |
| All-English (Veterinary) Malt Extract | None | |

MALT FLOURS PRODUCED FROM BARLEY AND/OR WHEAT GROWN IN ENGLAND AND WALES: GRADE DESIGNATIONS AND DEFINITIONS

| Grade Designation | Special Characteristics | |
|--------------------------------------|--|--|
| | Special Characteristics | Common Characteristics |
| All-English Malt Flour (White Bread) | Diastatic activity shall be not less than 40 Lintner value | <i>General.</i> The flour shall be the pure ground product of cleaned malted grain and be sound, free from taint or objectionable flavour and of good keeping quality. |
| All-English Malt Flour (Brown Bread) | None | <i>Special.</i> The maximum content of water shall be 10%, of ash 1.3%, and of fibre 2.5% of the total weight. |

MENTHA PIPERITA

Mentha Piperita (B.P.C.). Should contain not more than 2% of foreign organic matter, and yield not more than 2% of acid-insoluble ash. *Mentha Piperita*, U.S.P. XII, contains not more than 2% of stems more than 3 mm. in diameter, or other foreign organic matter.

Folia Menthae Piperitæ, P.G. VI, yields not less than 0.7% of volatile oil.

Oleum Menthae Piperitæ (B.P. Add. I). Contains 4.0 to 9% w/w of esters, calculated as menthyl acetate, $C_{12}H_{22}O_2$, and not less than 46% w/w of free menthol, $C_{10}H_{20}O$. Sp. gr., 0.902 to 0.915. α_D , -18° to -30° . n_{D20} , 1.460 to 1.470. Soluble in 4 volumes of alcohol (70%, sp. gr. 0.8896 to 0.8901). Assayed for ester content by boiling the neutralised oil with N/2 alcoholic potash for 1 hour and back titrating with N/2 sulphuric acid, and performing a blank; the acetylated oil obtained by boiling gently for 2 hours with acetic anhydride and anhydrous sodium acetate, washing the product and drying over anhydrous sodium sulphate, is treated as

for the ester determination. The free alcohols are calculated from the ester values of the original and acetylated oils using the B.P. formula. *Oleum Menthae Piperitæ, U.S.P. XII*, contains not less than 5% of esters as menthyl acetate, and not less than 50% of total menthol, free and as esters. Assayed similarly to the B.P. process and an equation for calculation is given.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined oil of peppermint, for food purposes, as the volatile oil obtained from peppermint (*Mentha piperita* L.), containing not less than 50% by weight of menthol.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

English and American oils are distilled from *Mentha piperita*. Two varieties are used, black and white; the former gives the larger yield of oil and is almost exclusively used, but the latter gives an oil of finer quality.

Studies of the genus *Mentha*.—Kremers, *Perfum. essent. Oil Rec.*, 1925, 409, and *ibid.*, 1926, 90.

For identity of aldehydes, ketones, etc., in American oil, also American peppermint distillation, see Bulletin No. 1555, U.S. Dept. of Agriculture, which also gives details of types of plants, soil, cultivation and distillation. Tabulated figures for a large number of oils taken over two seasons are given by Lazell (*Perfum. essent. Oil Rec.*, 1928, 193).

Evaluation of menthone in peppermint oil. Determination as the semicarbazone is compared with the oxime method.—Reilley, Moonan and Drumm, *Perfum. essent. Oil Rec.*, 1931, 378.

In the determination of menthol the time of acetylation may be varied within wide limits, but the time of saponification should be not less than 45 minutes and not more than 60 minutes in order to get concordant results.—L. H. Baldinger, *J. Amer. pharm. Ass.*, 1939, 155.

Japanese peppermint oil is obtained from *Mentha arvensis*. Undementholised oil contains about 85% of menthol, dementholised oil about 50%; both varieties are commercial oils. Details of the distillation of peppermint oil in Japan are given in *Perfum. essent. Oil Rec.*, 1931, 241. For the constitution of the high boiling fraction of Japanese oil see Shinosaki and Nagasawa, *Perfum. essent. Oil Rec.*, 1931, 172.

The principal terpenes in the oil are limonene and α -pinene, and the sesquiterpene fraction is mostly caryophyllene.—Duncan and Short, *J. Soc. chem. Ind., Lond.*, 1931, 198 T.

Some difficulty has been experienced in obtaining American oils containing the B.P. limit for free menthol. Japanese oil, from *Mentha arvensis*, is not B.P., and redistilled Japanese mint oils will no longer conform to B.P. tests.—C. T. Bennett, *Pharm. J.*, i/1933, 150.

For details of the production and analytical characters of Franco-Mitcham peppermint oil see *Perfum. essent. Oil Rec.*, 1926, 170, and for Italo-Mitcham oil see *Pharm. J.*, i/1935, 289.

A peppermint oil from WESTERN AUSTRALIA compared favourably with the best American production and closely resembled English distilled oil.—E. J. Parry, *Perfum. essent. Oil Rec.*, 1924, 188.

Determination of Menthone. 2 to 3 g. of oil is added to 20 ml. of a 5% solution of hydroxylamine in alcohol. N/2 alcoholic potash is then added, using methyl orange as indicator and keeping the mixture slightly acid, until finally neutralised. Each ml. of N/2 alkali = 0.077 g. of menthone.—G. Perraud, *per Quart. J. Pharm.*, 1936, 120.

Detection of Japanese Mint Oil in Peppermint Oil. A test depending on the colour produced by furfuraldehyde which is present in Japanese mint oil. 0.1 ml. of oil is mixed in a test tube with 5.0 ml. of a 2% solution of freshly distilled aniline in glacial acetic acid, added from a burette. The reaction mixture is examined in a 1 cm. cell of a Lovibond tintometer after an interval of 10 minutes. The reaction mixture must be protected from bright light. Japanese mint oils show a red value from 4.5 to 7.4 whilst peppermint oils give a value of 1.0 or less.—D. C. Garratt, *Analyst*, 1935, 369. The application of this test to other oils, light camphor oil in rosemary oil and clove oil in bay oil or pimento berry oil.—D. C. Garratt, *Analyst*, 1935, 595.

Mentha Viridis (*U.S.P. XII*). Contains not more than 2% of stems more than 3 mm. in diameter, or other foreign organic matter.

Oleum Menthæ Viridis (*B.P.C.*). By the method of the *B.P.* for carvone by digestion with hydroxylamine hydrochloride and titration of the liberated acid with N/1 alcoholic potash to dimethyl yellow, not less than 42% of carvone is indicated. Sp. gr., 0.920 to 0.940. α_D , -34° to -55° . n_{D20° , 1.483 to 1.490. Soluble in three volumes of alcohol (90%, sp. gr. 0.8334 to 0.8340). Oleum Menthæ Viridis, *U.S.P. XII*, yields by the sodium sulphite absorption not less than 50% by volume of carvone; sp. gr. at 25° , 0.917 to 0.934; α_D at 25° , -48° to -59° ; n_{D20° , 1.4840 to 1.4910.

Oleum Pulegii (*B.P.C.*). Contains not less than 85% *v/v* of pulegone. Sp. gr., 0.930 to 0.960; α_D , $+14^\circ$ to $+28^\circ$; n_{D20° , 1.475 to 1.490. Soluble in three volumes of alcohol (70%, sp. gr. 0.8896 to 0.8901). Assayed by measurement of the oil unabsorbed by sodium sulphite solution and deduction from the original volume.

Menthol (*B.P.*, *B.P. Add. I* and *B.P. Add. IV*). Consists of lævo-menthol (obtained from the volatile oils of various species of *Mentha*), or prepared synthetically, synthetic racemic menthol, or mixed isomeric menthols (any mixture of the stereoisomers of *p*-menthan-3-ol). Complies with tests for neutrality and absence of phenolic substances. Residue on evaporation from an open dish on a water-bath, not more than 0.05%. M.p. of lævo-menthol, 42° to 44° , α_D at 20° of 10% *w/v* solution of lævo-menthol in alcohol (90%), -49° to -50° . Freezing point of racemic menthol, -27° to -28° , rising on stirring to 30° to 32° ; m.p., 32.5° to 34° ; optically inactive. M.p. of mixed isomeric menthols, not below 31.5° . Menthol, *U.S.P. XII*, has a m.p. of 41° to 43° , and complies with tests for wax, paraffin or inorganic substances, and for thymol.

An official method for the determination of menthol is described in *Methods of Analysis* (*A.O.A.C.*, 1940, 599). The menthol is acetylated with acetic anhydride and sodium acetate and a definite amount of the washed and dried acetylated oil refluxed with an excess of potassium hydroxide. On cooling, the excess of alkali is titrated with sulphuric acid, using phenolphthalein as indicator. The percentage of menthol is calculated from the formula: $-A \times 7.808 \div [B - (A \times 0.021)]$, where A is the volume of potassium hydroxide solution used, and B the weight of acetylated oil taken.

MYRISTICA

Myristica (*B.P.*). Nutmegs should consist only of the dried kernels of *Myristica fragrans*. Myristica, *U.S.P. XII*, yields not less than 25% of non-volatile, ether-soluble extractive and not more than 0.5% of acid-insoluble ash.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined nutmeg as the dried seed of *Myristica fragrans* Houtt, deprived of its testa, with or without a coating of lime, containing not less than 25% of non-volatile ether extract, not more than 10% of crude fibre, not more than 5% of total ash nor more than 0.5% of ash insoluble in hydrochloric acid. Macassar nutmeg, Papua nutmeg, male nutmeg, long nutmeg, was defined as the dried seed of *Myristica argentea* Warb., deprived of its testa.—*S.R.A., F.D. No. 2, Rev. 5, Nov. 1936.*

Oleum Myristicæ (B.P.). Sp. gr., 0.880 to 0.925. α_D , $+10^\circ$ to $+30^\circ$; n_{D20° , 1.474 to 1.488. Residue on evaporation in a flat dish on a water-bath, not more than 3%. Soluble in three volumes of alcohol (90%, sp. gr. 0.8334 to 0.8340). The *B.P. Add. I* specifies that the evaporation for determination of non-volatile residue be made from a flat-bottomed dish, 9 cm. diameter and 1.5 cm. in depth. The *U.S.P. XII* oil has a sp. gr. at 25° of 0.880 to 0.910; α_D at 25° , $+10^\circ$ to $+30^\circ$; n_{D20° , 1.4740 to 1.4880; residue on evaporation, not more than 2%.

Oleum Myristicæ Deterpenatum (B.P.C.). Soluble in three volumes of alcohol (80%, sp. gr. 0.8634 to 0.8640). Sp. gr., 1.040 to 1.100; α_D , $+1^\circ$ to $+14^\circ$; n_{D20° , 1.500 to 1.533.

Mace. The Food and Drug Administration of the U.S. Dept. of Agriculture defined mace as the dried arillus of *Myristica fragrans* Houtt., containing not less than 20% nor more than 30% of non-volatile ether extract, not more than 10% of crude fibre, not more than 3% of total ash, and not more than 0.5% of ash insoluble in hydrochloric acid. Macassar mace, Papua mace: the dried arillus of *Myristica argentea* Warb.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

The Nutmeg Industry. The principal sources of supply are the Dutch East Indies and Granada, the former exporting about three times as much as the latter. East Indian nutmegs are "round," i.e., nearly spherical. Granada nutmegs are mixed "round" and "long," i.e., length exceeding diameter by $1\frac{1}{2}$ to 2 times. Granada nutmegs are not inferior but are liable to be confused with the Papuan (New Guinea) false long nutmeg derived from *M. argentea*, which is of inferior quality, but resembles the genuine in external appearance.—*Bull. imp. Inst., Lond., 1933, 31, 2, 197.*

NICOTINA

The specification of the Association of British Insecticide Manufacturers (Bulletin No. 82: Ministry of Agriculture and Fisheries) for nicotine requires the material to be free from coal tar bases and the nicotine content to be declared.

A tentative method for the determination of free nicotine in tobacco is described in *Methods of Analysis (A.O.A.C., 1940, 141)*. The powdered sample is stirred with water and the pH of the latter then measured in a quinhydrone or hydrogen electrode. The nicotine content is found from a curve plotted from data given for pH and nicotine content. An official method for the determination of nicotine in tobacco insecticides is also described (*ibid.*, 64). The sample is steam-distilled with aqueous alkali and paraffin and the distillate collected in hydrochloric acid. When the liquid distilling is free from nicotine (as shown with silico-tungstic acid) the distillate is adjusted to volume and filtered. An aliquot is treated with dilute hydrochloric acid and silico-tungstic acid (12% of $4H_2O \cdot SiO_2 \cdot 12NO_3 \cdot 22H_2O$) and stood overnight. The collected precipitate is washed with hydrochloric acid and ignited. Wt. of residue $\times 0.1140$ = nicotine.

The determination of nicotine by the process of Phyl and Schmidt depends upon the precipitation of the distillate (neutralised to methyl red) with 0.05M picric acid, and titration of the washed picrate in water and toluene mixture with N/10 sodium hydroxide using phenolphthalein indicator. The volume of distillate is reduced by saturating the liquor with salt, using magnesia for liberation of the nicotine.

Determination in Forensic Material. Mix the material, finely chopped, with citrate buffer and papayotin, the proteolytic enzyme from papaya, previously activated with hydrocyanic acid. Preserve with toluene and incubate at 40° for 48 hours with frequent shaking. Heat for 1 hour on a water-bath, filter,

wash residue with acidulated water, and evaporate the combined filtrates to small volume. Extract with ether, acidified, once, and with ether in strongly alkaline solution three times. Treat the ethereal extracts with a solution of picric acid in ether, filter off the precipitated nicotine dipicrate and weigh.—F. Halstrom, per *Chem. Abstr.* 1939, 89.

Insecticides. The Association of British Insecticide Manufacturers have prepared approved specifications with method of analysis, for certain insecticides and fungicides. By requiring such substances to comply with the specifications, purchasers are able to obtain standard products of high quality.

The products include lead arsenate in powder or paste, lime-sulphur solution, nicotine and nicotine sulphate, copper sulphate, burgundy powder, cheshunt compound, soft soaps for spraying, sodium, potassium and calcium cyanides, and formaldehyde.—Bulletin No. 82, 1934, Ministry of Agriculture and Fisheries.

Anabasine—Distinction from Nicotine. Anabasine, $C_{10}H_{14}N_2$, an insecticidal alkaloid from *Anabasis aphylla* (Chenopodiaceæ) occurs commercially as the sulphate in the form of a syrupy liquid almost identical in appearance and odour with commercial nicotine sulphate. It may be distinguished by adding to an ethereal solution of iodine. Nicotine gives a turbidity which, in a closed test-tube, settles into large red crystals of the periodide. Anabasine solutions remain clear.—S. A. Katz, *Z. anal. Chem.*, 1937, 108, 408.

NITROGLYCERINUM

Liquor Glycerylis Trinitratis (B.P.). Determined by digesting in a closed tube with one-tenth its volume of sodium hydroxide solution for 1 hour, transferring with alcohol to a brine-charged nitrometer and shaking with equal volumes of potassium iodide solution and dilute sulphuric acid; each millilitre of nitric oxide produced at 15.5° and normal pressure is equivalent to 0.00505 g. of $C_3H_5O_9N_3$; from 0.9 to 1.1% *w/v* should be indicated. Alcohol content, 88 to 90% *v/v* of ethyl alcohol. Spiritus Glycerylis Trinitratis, *U.S.P. XII*, contains from 1 to 1.1% of $C_3H_5(NO_2)_3$, determined by the general method for nitrites after absorption in sodium hydroxide solution, as described under Spiritus Æthylis Nitritus, *U.S.P. XII*, the iodine liberated on addition of potassium iodide to an acidified solution being titrated with N/10 sodium thiosulphate. Nitroglycerinum solutum, *P.G. VI*, and Nitroglycerinum solutum, *P. Helv. V*, contain 0.98 to 1.02% of $C_3H_5(ONO_2)_3$; assayed similarly by addition of N/2 alcoholic potash, water and hydrogen peroxide solution, warming till decolorised, and titrating the warm solution with N/2 hydrochloric acid to phenolphthalein; a blank titration is performed. 1 ml. N/2 potash = 0.0022706 g. nitroglycerin.

An official quantitative method for the determination of glyceryl trinitrate (nitroglycerin) is described in *Methods of Analysis* (A.O.A.C., 1940, 478).

Determination in Tablets. One tablet reputed to contain 1/100 gr. is crushed finely and macerated in 2.5 ml. of glacial acetic acid for 2 hours. 1 ml. of the filtered liquid is transferred to a suitable 10 ml. tube and, with the tube immersed in cold water, 0.25 ml. of a 0.5% solution of diphenylamine in nitrogen-free sulphuric acid is added. The tube is agitated in the cold water and after 3 minutes diluted to the 10 ml. mark with glacial acetic acid. The depth of colour is then compared with that given by similarly and simultaneously treating 2.4 ml. of standard solutions of KNO_3 in glacial acetic acid. For 1/100 gr., 1/150 gr. and 1/200 gr. trinitrin, standard solutions of KNO_3 should contain

per 100 ml. of glacial acetic acid 0.0340 g., 0.0231 g. and 0.0173 g. respectively.—C. H. Sykes, *Pharm. J.*, ii/1933, 267.

In tablets or solution, nitroglycerin can be determined by reduction with Devarda alloy and distillation of the ammonia in standard sulphuric acid. A quantity of the preparation representing about 0.05 g. of nitroglycerin is mixed in an 800 ml. Kjeldahl flask with 50 ml. of a saturated sodium sulphate solution, 150 ml. of water and sufficient 10% sulphuric acid to make the mixture acid to litmus. The mixture is distilled into a flask containing 30 ml. of 5% sodium hydroxide solution and reduction effected by means of 2 g. of Devarda alloy.—E. L. Anderson, *J. Ass. off. agric. Chem., Wash.*, 1932, 140.

The U.S.P. XII gives the following method for Tabellæ Glycerylis Trinitratis, containing 80 to 112% of the labelled amount of $C_3H_5(NO_3)_3$. Triturate in a mortar tablets equivalent to 0.05 g. of glyceryl trinitrate with 50 ml. of ether. Decant the ether into a stoppered flask and extract a further 4 times with 30 ml. portions of ether; shake the flask for 15 minutes and filter into a beaker, washing with 50 ml. of ether. Cautiously evaporate the ether to about 5 ml. and transfer with ether to an 800 ml. Kjeldahl flask containing 100 ml. of water and add a mixture of 30 ml. of N/1 sodium hydroxide, 60 ml. of water and 10 ml. of potassium permanganate solution (5%), followed by 100 ml. of water; mix, stand for 30 minutes, and then heat on a water-bath for 30 minutes. After cooling add 3 g. of Devarda's alloy, stopper the flask immediately with a stopper carrying a scrubber, and connect with a vertical condenser, the receiver containing 50 ml. of N/50 sulphuric acid. Heat gently while hydrogen is evolved and then distil two-thirds of the liquid. Back titrate with N/50 sodium hydroxide using methyl red indicator and run a blank determination. 1 ml. N/50 sulphuric acid = 0.001514 g. $C_3H_5(NO_3)_3$.

IMPROVED METHODS FOR TABLETS. (a) Place five tablets in a 500 ml. Kjeldahl flask, add 25 ml. of saturated sodium sulphate solution, 75 ml. of water and sufficient sulphuric acid to make just acid to litmus paper (usually 0.3 ml. of N/1 sulphuric acid is required). Distil just to dryness, using a still head, into a flask containing 10 ml. of N/10 sodium hydroxide, keeping the outlet tube below the surface of the alkali. Wash down the condenser and outlet tube and evaporate the sodium hydroxide solution to dryness. Add 2 ml. of water, 0.3 g. (± 0.01 g.) of reduced iron and 2 ml. of 50% v/v sulphuric acid, allow to stand for 10 minutes and boil for 2 minutes. Transfer the acid solution to a steam distillation apparatus, make alkaline with 4 ml. of saturated sodium hydroxide solution, and distil the liberated ammonia into a flask containing 10 ml. of N/10 sulphuric acid until the distillate measures 500 ml. Take 100 ml. of the distillate, add 2 ml. of Nessler's reagent and compare the colour produced with that produced by adding the same amounts of reagent to 100 ml. of a solution containing ammonium chloride equivalent to 0.1 mg. of nitrogen. The colours produced are most easily compared in a colorimeter, but a tintometer or even Nessler glasses could be used for the purpose. Whatever means of comparing the colours is used the colour of the unknown should not vary more than 20% from that of the standard. A control experiment must always be carried out exactly as described.—Wilfred Smith, *Quart. J. Pharm.*, 1935, 370.

(b) Add the powdered tablets equivalent to about 1 ml. of nitroglycerin to 5 ml. of glacial acetic acid in a stoppered cylinder and shake for 1 hour. Filter and to 1 ml. add 2 ml. of phenoldisulphonic acid, stir and stand for fifteen minutes. Dilute with 8 ml. of water, make alkaline with ammonia, cool, adjust to 20 ml. at 20° and filter. Compare the colour with controls prepared with a known solution of nitroglycerin or with 1 ml. of a 0.225% silver nitrate solution. The colour produced in each case should be equal to 7.0 Lovibond yellow units when viewed in a cell 1 inch internal width.—H. O. Meek, *Quart. J. Pharm.*, 1935, 375.

The second report of the Commission Internationale des Spécialités includes an agreed method for the determination of glyceryl trinitrate in tablets in which the medicament is extracted with chloroform and an aliquot part of the chloroform solution diluted with ether is mixed with alcohol and alkali and allowed to stand for 10 minutes. After evaporation on a water-bath the residue is transferred to a 100 ml. flask using about 90 ml. of water, 2 ml. of Griess-Romijn reagent added, water added to volume and the colour produced in 15 to 30 minutes is compared with that obtained by similarly treating a standard sodium nitrite solution.

Griess-Romijn Reagent. α -Naphthylamine 1 g., sulphanilic acid 10 g., tartaric acid 89 g., in water 900 g. .

Erythritylis Tetranitras Dilutus (B.P.). Contains from 47·5 to 52·5% of $C_4H_6O_{12}N_4$. Estimated by the Kjeldahl method, using salicylic acid with the sulphuric acid for digestion; a blank estimation is performed using half the weight of lactose; each millilitre of N/10 sulphuric acid is equivalent to 0·007552 g. of $C_4H_6O_{12}N_4$. Erythritylis Tetranitras Dilutus, *U.S.P. XI*, is replaced by Tabellæ Erythritylis Tetranitratis, *U.S.P. XII*. Assayed by repeated extraction with ether, evaporation below 35° and drying over sulphuric acid for 18 hours, the tablets are required to contain 93 to 107% of the amount stated on the label.

NUX VOMICA

Nux Vomica (B.P.). Contains not less than 1·2% of strychnine and not more than 1% of foreign organic matter. Assayed by continuous extraction with a mixture of alcohol, dilute solution of ammonia and chloroform (12:1:4), followed by evaporation of the solvent and extraction with sulphuric acid from a chloroform mixture; the total alkaloids are then extracted with chloroform from ammoniacal solution, the solvent evaporated, alcohol added, and evaporated; the residue is dissolved in 15 ml. of 3% sulphuric acid and 2 ml. of nitric acid, allowed to stand for 30 minutes at 15° to 20°, made alkaline with sodium hydroxide and extracted with chloroform; the residual strychnine, after drying for 30 minutes at 100°, is titrated with N/10 sulphuric acid to methyl red or cochineal, multiplying the result by 1·02 to correct for loss.

Nux Vomica, *U.S.P. XII*, contains not less than 1·15% of strychnine; assayed by the aliquot part method, maceration with ether-chloroform and extraction of the total alkaloids with chloroform and ammonia from the acid solution; the total alkaloid is purified by transferring again to acid and a further extraction with chloroform and ammonia; after evaporation of the chloroform the alkaloidal residue is dissolved in 15 ml. of sulphuric acid (3%) and 1·5 ml. of nitric acid mixed with 1·5 ml. of sodium nitrite (5%) solution is added; after 10 minutes only, the strychnine is extracted from the liquid made alkaline with sodium hydroxide (10%) solution with chloroform, finally titrating the strychnine; no correction for loss of strychnine is used.

Noix Vomique, *Fr. Cx.* 1937, determined by titration after extraction with ether-chloroform, contains 2 to 3% of total alkaloids of which not less than 45% is strychnine; for strychnine separation the first titration liquid with sulphuric and nitric acids is kept at 50° to 60° for 10 minutes, extracted with chloroform and ammonia, transferred to acid, finally extracted with ether-chloroform, dried at 105° and the residue of strychnine weighed. Semen Strychni, *P.G. VI*, contains not less than 5% of total alkaloid of

Strychnos nux vomica Linné. Semen Strychni, *P. Helv. V*, contains not less than 2.5% of total alkaloids and the powder for administration is adjusted with lactose to contain 2.5% of total alkaloids. *I.A.* (Second) recommended a standard of 2.5% of total alkaloids.

Strychnos cinnamomifolia from Travancore. Total alkaloidal content from 2.432 to 2.801%, only about 0.3% being strychnine. The seeds closely resemble those of *S. Nux-vomica*, but have not been commercially exploited.—G. R. A. Short, *Yearb. Pharm.*, 1924, 646.

Benzol (*B.P.* '98) is not such a good solvent for strychnine as chloroform but is advised, in preference to the latter, if used in larger quantity for extraction in the estimation process: it does not emulsify.—H. Deane, *Pharm. J.*, ii/1924, 96. See also D. B. Dott, *ibid.*, 251.

Assay. The following method is claimed to give more consistent results than those usually employed. In the case of the powdered seed 4.5 g. of the material is first shaken with 15 g. of chloroform and 30 g. of ether; for the extract, 0.75 g. is dissolved in 10 ml. of water with the addition of 1 ml. of dilute sulphuric acid, and shaken with chloroform and ether; for the tincture, 45 g. is treated with 1 ml. of dilute sulphuric acid, evaporated to about 5 g. and treated with 15 g. of chloroform and 30 g. of ether. In all cases 6 g. of 25% sodium carbonate solution is added, and the alkaloids are shaken into the chloroform-ether mixture. The mixture is cleared if necessary by the additions of powdered tragacanth, and strained through cotton wool, 30 g. of the filtrate being then evaporated nearly to dryness and treated with 10 ml. of N/10 hydrochloric acid and 20 ml. of water. The remainder of the chloroform is evaporated off and, after cooling, the mixture is filtered through cotton wool, the filter being washed with water to make the total volume up to about 100 ml. This solution is now titrated with N/10 sodium hydroxide, using methyl red as indicator. One ml. of the acid is taken as equivalent to 0.0364 g. of strychnine+brucine.—A. Jermstad, *Norsk. farm. Tidsskr.*, 1936, 44, 375, 388.

A colorimetric method for the determination of strychnine in nux vomica and its preparations is described. The procedure involves the rapid extraction of the total alkaloids by addition of piperazine to the powdered drug followed by treatment with boiling tetrachloroethylene, transference of the extracted alkaloids to dilute aqueous sulphuric acid and isolation of the strychnine as the ferrocyanide. The determination is completed by applying Malaquin's colour test as modified by Deniges.—J. Allen and N. Allport, *Quart. J. Pharm.*, 1940, 252.

The potency of nux vomica preparations as indicated by their toxicity is not in agreement with the results obtained by chemical assay for total alkaloids. Although better agreement is sometimes obtained between toxicity and strychnine content, in other samples marked discrepancies were observed.—J. C. Munch *et al.*, *J. Amer. pharm. Ass.*, 1937, 29.

Nux Vomica Pulverata (B.P.). Adjusted with nux vomica of higher or lower alkaloidal content, or with lactose, to contain 1.14 to 1.26% of strychnine. Ash, not more than 3%.

Extractum Nucis Vomicae Siccum (B.P.). After extraction with alcohol (50%) and completion of the assay as for Nux Vomica, it contains 4.75 to 5.25% of strychnine; Extractum Nucis Vomicae, *N.F. VII*, contains 7 to 7.75% of strychnine. Assayed by digestion with dilute alcohol acidified with acetic acid and after addition of chloroform and ammonia, proceeding as for Fluidextract of Nux Vomica, *N.F. VII*.

Extractum Nucis Vomicae Liquidum (B.P.). Contains 1.425 to 1.575% w/v of strychnine.

Tinctura Nucis Vomicae (B.P.) contains 0.119 to 0.131% *w/v* of strychnine. The tincture of the *U.S.P. XII* contains 0.105 to 0.125% *w/v* of strychnine.

Brucina Sulphas (N.F. VII). $(C_{23}H_{18}O_4N_2)_2 \cdot H_2SO_4 \cdot 7H_2O = 1013.1$. Loss at 100°, not more than 13%; ash, not more than 0.1%. A test for strychnine is included in which after destroying the brucine with nitric and sulphuric acids, making alkaline, extracting with chloroform and evaporating, the residue should produce no violet colour with sulphuric acid and potassium dichromate.

Strychnina (B.P.C.). $C_{21}H_{22}O_2N_2 = 334.2$. By titration in excess N/10 sulphuric acid with N/10 sodium hydroxide to cochineal, a purity of not less than 99% should be indicated. Ash, not more than 0.1%. A limit test for brucine is included; no reddish colour should be produced with a mixture of equal parts of nitric acid and water. *Strychnina, N.F. VII*, should yield not more than 0.1% of ash.

Extraction from Viscera. In the extraction of alkaloidal poisons from viscera the laborious and time-consuming Stas-Otto process may be replaced by treatment of the minced material with trichloroacetic acid. This at once yields a water-clear filtrate free from protein and fat and containing the whole of the alkaloid originally present. From this filtrate the alkaloid can conveniently be removed by absorption on kaolin, from which after neutralisation it is eluted by hot chloroform.—C. P. Stewart, S. K. Chatterji and S. Smith, *Brit. med. J.*, ii/1937, 790.

Spectrum of Strychnine. The smallest quantity, e.g., 1/500 grain, can be detected—useful in cases of poisoning. Alkaloids generally give characteristic spectra.—Prof. J. J. Dobbie.

The strychnine compound of bordeaux B (strychnine azorubrate) can be decomposed during the assay of preparations containing strychnine and bordeaux B by allowing sodium hydroxide to act on the substance for two or three days before extracting with an organic solvent. This gives an almost theoretical yield of pure strychnine.—J. B. Dott, *Pharm. J.*, ii/1939, 527.

Strychninae Hydrochloridum (B.P.). $C_{21}H_{22}O_2N_2 \cdot HCl \cdot 2H_2O = 406.7$. Should lose not less than 7% and not more than 9% at 110°. Ash, not more than 0.1%.

Liquor Strychninae Hydrochloridi (B.P.). Contains 0.95 to 1.05% *w/v* of strychnine hydrochloride. Determined by extraction with chloroform from ammoniacal mixture, drying at 100° and titration with excess N/10 sulphuric acid and N/10 sodium hydroxide, using methyl red or cochineal indicators.

Volumetric estimation of Liq. *Strychninae*, using N/10 potassium dichromate, which precipitates the alkaloid quantitatively from slightly acid solution.—J. Rae, *Pharm. J.*, i/1928, 270.

Strychninae Nitras (B.P.C.). $C_{21}H_{22}O_2N_2 \cdot HNO_3 = 397.2$. Ash, not more than 0.1%. Complies with limit tests for brucine and sulphate. The *N.F. VII* salt should yield not more than 0.1% of ash and comply with tests for acidity, brucine, chloride and sulphate.

Strychninum nitricum is the only form of strychnine official in the *P. Helv. V*. When titrated with N/10 sodium hydroxide using phenolphthalein as indicator, it should contain not less than 99.5% of $C_{21}H_{22}O_2N_2 \cdot HNO_3$.

Tabellæ Strychninæ Nitratis (N.F. VII). Tablets of 20 mg. or more contain 92.5 to 107.5%, tablets of 20 mg. to 1.2 mg. contain 91 to 109% and tablets of less than 1.2 mg. contain 88 to 112%, of the labelled amount of strychnine nitrate, including all tolerances. Assayed by macerating with water and dilute sulphuric acid overnight, filtering and extracting with chloroform an aliquot of the filtrate, made alkaline with ammonia solution, removing the chloroform and dissolving the residue in N/20 sulphuric acid, finally back titrating with N/50 sodium hydroxide using methyl red indicator.

Strychninæ Phosphas (N.F. VII). $C_{21}H_{22}O_2N_2 \cdot H_3PO_4 \cdot 2H_2O = 468.4$. By extraction of the alkaloid with chloroform from a solution rendered ammoniacal and final titration with N/10 sulphuric acid, using methyl red indicator, it yields 70 to 73% of strychnine. Complies with tests for readily carbonisable substances, chloride, sulphate and brucine.

Strychninæ Sulphas (B.P.C.). $(C_{21}H_{22}O_2N_2)_2 \cdot H_2SO_4 \cdot 5H_2O = 856.5$. Loss at 100° , 9 to 11%. Ash limit, 0.1%. Complies with the limit test for brucine. Strychninæ Sulfas, *U.S.P. XII*, leaves not more than 0.1% of ash, loses not more than 11.5% at 105° and complies with tests for acidity and brucine; 0.2 g. complies with the specified test for carbonisable substances.

Tabellæ Strychninæ Sulfatis (U.S.P. XII). Contain 93 to 107% of the labelled amount of $(C_{21}H_{22}O_2N_2)_2 \cdot H_2SO_4 \cdot 5H_2O$ for tablets of 20 mg. or more, and 90 to 110% for tablets of less than 20 mg., including all tolerances. Assayed by macerating overnight a weighed quantity of powdered tablets with water and dilute sulphuric acid, filtering and extracting the alkaloid with chloroform from an aliquot of the filtrate made alkaline with ammonia solution. To the combined extracts 10 ml. of dehydrated alcohol is added for each 50 ml. of chloroform and the mixture evaporated almost to dryness. The residue is dissolved in alcohol and N/50 sulphuric acid and the excess acid titrated with N/50 sodium hydroxide using methyl red indicator.

Garratt (*Drugs and Galenicals*) recommends determination of small amounts of strychnine by the method of Scandola (*Analyst*, 1911, 144). The residue containing about 0.1 mg. is treated with 0.1 g. ammonium vanadate and 3 drops of sulphuric acid, diluted to volume, and matched against a control solution.

Determination of Strychnine in Presence of Caffeine. For determining small quantities of strychnine in the presence of caffeine, e.g., in Syr. Glycero-phosph. Co., the following procedure is suggested. To 50 ml. of syrup add 5 g. of citric acid, make alkaline with ammonia and extract five times with chloroform. Evaporate the solvent and weigh the anhydrous residue. Dissolve in 25 ml. of water containing 1 ml. of 25% *v/v* sulphuric acid, add 1 ml. of freshly prepared 5% potassium ferrocyanide, stir, and allow to stand overnight. Filter, wash well with slightly acidified water, place the funnel in the neck of a separator, pierce the filter paper and wash in the precipitate successively with 10 ml. of 10% ammonia, 10 ml. of water and 10 ml. of chloroform. Extract three times with chloroform, evaporate with 5 ml. of alcohol, dry, and weigh.—D. C. Garratt, *Analyst*, 1937, 538.

Determination of Small Quantities. Strychnine in amounts as low as 5 mg. can be determined by precipitation with a standard potassium mercuric iodide solution and back-titration of the excess iodide with potassium iodate. The reagent is prepared by dissolving 0.46 g. of mercuric iodide and 0.40 g. of potassium iodide in water to 100 ml. and is standardised against M/100 potassium iodate solution (1.0701 g. dried at 120° in 1% hydrochloric acid to 500 ml.). The strychnine is dissolved in 2 to 3 ml. of dilute acid, a known volume of reagent added (at least 1 ml. for each 3 mg. of strychnine), the mixture diluted to 25 ml. in a graduated flask and allowed to stand in the dark for 1 to 2 hours. It is then filtered, rejecting the first 2 to 3 ml. of filtrate, and 20 ml. is transferred to a stoppered bottle. 16 ml. of concentrated hydrochloric acid is added, the mixture cooled and then titrated with iodate solution, chloroform being added to indicate the end-point. 1 ml. of M/100 iodate solution is equivalent to 2.228 mg. of anhydrous alkaloid, 2.648 mg. of anhydrous nitrate and 2.855 mg. of sulphate ($5H_2O$). The process is applicable to tablets containing sucrose, lactose or starch.—A. G. Murray, *J. Ass. off. agric. Chem., Wash.*, 1937, 638.

Official methods for the determination of strychnine in tablets and liquid preparations (other alkaloids being absent) are described in *Methods of Analysis* (A.O.A.C., 1940, 591).

Denigès' modification of Malaquin's colour test for strychnine has been applied to the determination of strychnine in hypodermic tablets and injections. Tables are given correlating the value of the red component of the colour obtained to the alkaloidal content.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 245.

Picrotoxinum (U.S.P. XII). M.p., 198° to 200°. Complies with tests for absence of alkaloids.

ŒSTRADIOL

(with other ŒSTROGENS, PROGESTERONE and the ANDROGENS)

Œstradiol (B.P.C. Supp. IV). $C_{18}H_{24}O_2 = 272.2$. M.p., 175° to 178°. α_D of 1% solution in dioxan, +75° to +82°. α_D at 17°, of the *Fr. Cx.* substance, determined on a 1% solution in dioxan, +80°.

Œstradiolis Benzoas (B.P.C. Supp. IV). $C_{25}H_{28}O_3 = 376.2$. M.p., 189° to 195°. α_D of 1% w/v solution in dioxan, +58° to +61°. Loss at 100°, not more than 0.5%. Ash, not more than 0.1%. Preparations may be assayed by comparison with the standard by a method depending on its power to promote in adult female rats or mice, completely deprived of their ovaries, the cellular changes in the vaginal secretion characteristic of normal Œstrus. The potency may be stated in units, the unit being the Œstrus-producing activity of 0.0001 mg. of the standard preparation of pure crystalline Œstradiol monobenzoate issued by the National Institute of Medical Research, London, and adopted as the International Standard. *Œstradiolis Benzoas*, U.S.P. XII, melts between 191° and 196°; α_D determined on a 2% solution in dioxan, +58° to +63°. α_D of the *Fr. Cx.* substance, determined on a 1% solution in dioxan, +57.5°.

Œstriol (B.P.C. Supp. IV). $C_{18}H_{24}O_3 = 288.2$. M.p., about 282°. α_D of 1% solution in dioxan, +53° to +63°.

Œstronum (B.P.C. Supp. IV). $C_{18}H_{22}O_2 = 270.2$. M.p., 255° to 260°. α_D of 1% w/v solution in dioxan, +157° to +167°. Loss at 100°, not more than 0.5%. Ash, not more than 0.1%. May be assayed by biological comparison with the standard preparation of pure crystalline Œstrone issued by the National Institute for Medical Research, London. *Œstronum*, U.S.P. XII, melts between 258° and 261°; α_D at 25°, determined on a 1% solution in dioxan, +155° to +165°. The substance of the *Fr. Cx.* melts at 259° to 260°, α_D at 15° of a 1% solution in dioxan, +165°.

Colorimetric Assay. The following method is based on the coupling of oestrone with *p*-diazobenzenesulphonic acid to give a red azo dyestuff which is compared with that of a standard produced by coupling β -naphthol in the same way. The reaction depends on the presence of a phenolic group and is therefore given by both oestrone and oestriol.

The reagent is prepared by diazotising sulphanilic acid. 4.5 g. of the acid is dissolved in 500 ml. of water containing 45 ml. of concentrated hydrochloric acid. To 1.5 ml. of this solution is added 1.5 ml. of sodium nitrite solution (5% NaNO_2). The mixture is immersed in an ice-bath and after 5 minutes 6 ml. more of the nitrite solution is added. The solution is again cooled for 5 minutes in the ice-bath and then diluted to 50 ml. with water. The diluted acid is kept in the ice-bath and used not earlier than 15 minutes nor later than 24 hours after its preparation.

To (1-x) ml. of water is added 5 ml. of 1.1% anhydrous sodium carbonate solution and 2 ml. of the diazobenzenesulphonic acid reagent. Exactly 30 seconds later is added x ml. of the oestrone solution and 0.5 ml. of 10% NaOH . 1 ml. of dilute β -naphthol solution containing 0.01 mg. per 100 ml. is treated similarly and the colours compared in a colorimeter.

Assuming that equimolecular amounts of oestrone and β -naphthol take part in the reactions it was found that 0.01875 mg. of oestrone corresponded to 0.01 mg. β -naphthol. Using a solution of oestrone standardised in rat units it was found that 1 mg. = 2666 r.u.—M. J. Schmulovitz and H. B. Wylie, *J. biol. Chem.*, 1936, 116, 415.

Oestroni Benzoas (*B.P.C. Supp. IV*). $\text{C}_{25}\text{H}_{26}\text{O}_3 = 374.2$. M.p., about 220° . α_D of 1% solution in dioxan, about $+120^\circ$. M.p. of the substance of the *Fr. Cx.*, 218.5° to 221° ; α_D at 15° of 1% solution in dioxan, $+128^\circ$.

Stilboestrol (*B.P. Add. VI*). $\text{C}_{18}\text{H}_{20}\text{O}_2 = 268.2$. M.p., 168° to 171° . Loss at 100° , not more than 0.5%. Produces a clear or only slightly turbid solution with 30 parts of water and 30 parts of N/1 sodium hydroxide. Ash, not more than 0.1%. Assayed by acetylation and drying the acetate at 100° , it contains not less than 99% of $\text{C}_{18}\text{H}_{20}\text{O}_2$.

Colour Tests. *A. Violet Colour Reaction.* Mix equal volumes of 1% solution of stilboestrol and 5% v/v solution of bromine, both in glacial acetic acid, and warm in a water-bath for 1 minute. One drop of the resulting orange solution mixed with 5 drops of absolute alcohol followed by 2 ml. of water produces a deep violet colour. *B. Green Colour Reaction.* A green colour is produced when the 1% solution of stilboestrol is heated with the bromine solution in the proportion of 5 atoms of bromine per molecule of stilboestrol. In the presence of sucrose, e.g., sugar-coated tablets, the colour produced is a deep blue changing to dull purple and orange red.

The reactions are not given by stilboestrol dipropionate, stilboestrol acetate or hexaestrol. Dienaestrol gives both reactions but requires only about half the amount of bromine to produce a green colour. Details are given for the application of the first test to the rough colorimetric determination of stilboestrol.—T. T. Cocking, *Analyst*, i/1943, 144.

Stilboestrolis Dipropionas. $\text{C}_{32}\text{H}_{40}\text{COOC}_2\text{H}_5 \cdot \text{C}_2\text{H}_5 \cdot \text{C}(\text{C}_2\text{H}_5)_2 \cdot \text{C}(\text{C}_2\text{H}_5)_2 \cdot \text{C}_6\text{H}_4 \cdot \text{COO} \cdot \text{C}_2\text{H}_5$. M.p., about 103° . Saponification value, about 290. Ultra-violet absorption in dehydrated alcohol at $240 \text{ m}\mu$ (calculated on the substance dried at 100°), 390.

Biological Assay. Stilboestrol was tested against oestrone to find how much of each substance was required to produce oestrus in 50% of a large group of castrated rats. A curve could be drawn by plotting dosage against percentage in oestrus. Using the figure of 50% to indicate 1 unit, this was found to be 3 microgrammes as a single injection in oil for oestrone and 0.95 microgrammes for stilboestrol, while for multiple aqueous injections, the unit was 0.95 microgrammes for oestrone and 0.62 microgrammes for stilboestrol.—V. L. Koenig and R. G. Gustavson, *J. Pharmacol.*, 1940, 69, 355.

Progesteronum (*B.P.C. Supp. III*). $C_{21}H_{30}O_2 = 314.2$. M.p., 128° to 131° . α_D of 1% solution in dehydrated alcohol, $+183^\circ$ to $+194^\circ$. Loss at 100° , not more than 0.5%. Ash, not more than 0.1%. Hormone du Corps Jaune, *Fr. Cx.* 1937, should give a dioxime melting at 246° to 248° ; m.p., 121° ; α_D (0.775% solution in chloroform), $+200^\circ$; possesses the same activity as the international standard.

The international unit is defined as the activity of 1 mg. of the chemically pure substance, the activity being measured by the pregravid changes occurring in the uterine horn of immature female rabbits.

Assay. The induction of sexual receptivity in the ovariectomised guinea-pig previously conditioned by theelin serves as a sensitive and specific method for the assay of progesterone. As little as 0.05 i.u. can be detected and only one-tenth of the amount of progesterone needed in other methods of assay is required.—R. Hertz, R. K. Meyer and M. A. Spielman, *Endocrinology*, 1937, 533.

Testosteronum (*B.P.C. Supp. III*). $C_{19}H_{28}O_2 = 288.2$. M.p., 151° to 156° . α_D of 1% solution in dioxan, $+104^\circ$ to $+112^\circ$. Loss at 100° , not more than 0.5%. Ash, not more than 0.1%.

Detection of Ketones of the Sterol Group. Steroid ketones having a double bond conjugated with the keto group, such as testosterone, progesterone, corticosterone, etc., usually possess greater biological activity than the corresponding saturated ketone. A polarographic method of detection is described that is claimed to have many advantages over the existing colorimetric and spectrophotometric methods. Details are also given for the estimation of testosterone in an alcoholic testicle extract.—J. Eisenbrand and H. Picher, *Z. physiol. Chem.*, 1939, 260, 83.

Testosteroni Propionas (*B.P.C. Supp. III*). $C_{22}H_{32}O_3 = 344.25$. M.p., 118° to 122° . α_D of 1% solution in dioxan, $+83^\circ$ to $+90^\circ$. Loss at 100° , not more than 0.5%. Ash, not more than 0.1%.

OLEA ESSENTIALIA

The essential oils and natural perfumes are obtained by distillation, solvent extraction and cold and hot enfleurage processes. **Distillation** yields a true volatile oil but is not suitable where the yield of oil is very small or the product is damaged by heat. The principles of the distillation of essential oils are described in "A Treatise on Distillation," by Durrans (*Perfum. essent. Oil Rec.*, 1920, 154). **Solvent extraction** has largely displaced the enfleurage process for many perfumes, benzene and petroleum ether being used as solvents. The product obtained by the evaporation of the solvent contains, besides the odorous bodies, resins, waxes and colouring matter; these are separated more or less completely by treating the extract with alcohol, refrigerating, filtering and evaporating the alcohol to obtain "*absolutes*." Many perfumes are made by this process, of which the more usual are jasmine, orange-flower, carnation, violet, lilac, rose, cassia, and oak moss.

The enfleurage process, in which the odour of the flowers is taken up by repeatedly spreading fresh flowers on trays coated with fat, or by immersing them in melted fat, is still used for jonquil, jasmine, tuberose and a few others. The fat when sufficiently saturated, is extracted with alcohol, which is evaporated to leave the "absolute." Some account of the process is given in *Chem. & Drugg.*, i/1927, 319.

For further information as to sources, constituents, methods of distillation, yields, analytical and physical data, etc., see *Die Ätherischen Öle*, by Gildermeister and Hoffman; *Chemistry of Essential Oils and Artificial Perfumes*, by E. J. Parry; *Essential Oils*, by H. Finckmore; also Umney, *Perfum. essent. Oil Rec.*, July, 1912; and Bovill, *Mfg Chem.*, Jan.-Feb., 1932. For the chemistry of the terpenes, see Durran, *Perfum. essent. Oil Rec.*, 1929, 278, also L. Ruzicka, *ibid.*, 1934, 85 and 117.

Determination of Aldehydes. The following method is recommended by the Essential Oil Sub-Committee of the Committee on Uniformity of Analytical Methods for the determination of aldehydes in oils of cassia, cinnamon, lemon-grass, orange, bitter almond, cherry-laurel, cummin and terpeness oils of lemon and orange:—Weigh out exactly, into a glass-stoppered tube approximately 150 mm. long and 25 mm. in diameter, a suitable quantity of the oil, add 5 ml. of benzene and 15 ml. of N/2 hydroxylamine hydrochloride reagent; shake vigorously and titrate with N/2 alcoholic potash (60% alcohol) until the red colour changes to yellow; continue the shaking and titrating until the full yellow colour of the indicator is permanent in the lower layer after shaking vigorously for 2 minutes and then allowing to stand for the liquids to separate. The report should be consulted for further details and for the different factors employed.—*Analyst*, 1934, 105.

Determination of Esters. A method has been recommended by the Essential Oil Sub-committee of the Analytical Methods Committee. The report states that unless the conditions of the test are strictly adhered to considerable variations in results are likely to occur between different operators and different laboratories; the published details should therefore be studied. 2 ml. of oil (or other suitable quantity so that the amount of alkali added is at least double that required for saponification) is weighed into the saponification flask, 5 ml. of freshly well-boiled neutralised alcohol added and the free acid titrated with N/10 alcoholic potassium hydroxide using 0.2 ml. of 0.2% solution of phenolphthalein in alcohol (60%) as indicator. To the neutralised solution is added 20 ml. of N/2 alcoholic potassium hydroxide, and the mixture is boiled for 1 hour, at the end of which it is immediately titrated with N/2 acid using an additional 0.5 ml. of phenolphthalein solution. A blank determination is carried out simultaneously. The difference between the two titrations is calculated to the percentage of esters as usual, using the appropriate factor. Those for the most commonly occurring esters are:—

| | | | |
|--------------------|--------|----------------------|--------|
| Bornyl acetate .. | 0.0981 | Santalyl acetate .. | 0.1311 |
| Geranyl acetate .. | 0.0981 | Methyl salicylate .. | 0.0760 |
| Linalyl acetate .. | 0.0981 | Geranyl tiglate .. | 0.1181 |
| Menthyl acetate .. | 0.0981 | Linalyl benzoate .. | 0.1290 |

With oil of sweet birch and oil of wintergreen the free acid should be determined in a separate experiment by shaking 5 g. with 25 ml. of water and titrating with N/10 aqueous sodium hydroxide using phenol red as indicator. The saponification is carried out on the unneutralised oil and an allowance made for the free acid in calculating the results. The boiling to effect saponification should be continued for 1½ hours.—Report of Essential Oil Sub-Committee to the Analytical Methods Committee, per *Analyst*, 1937, 541.

Micro-Chemistry in the Domain of Essential Oils and Perfumery Materials. Apparatus and methods are described, qualitative tests, and characteristics of materials.—Rosenthaler, *Perfum. essent. Oil Rec.*, 1930, 277.

Oils are identified by the microscopical examination of the crystalline compounds of their constituents with potassium hydroxide, phenylhydrazine and sodium phenate, in various solvents.—W. Green, *Perfum. essent. Oil Rec.*, 1939, 309.

Determination of Alcohols in Essential Oils. A method using orthophosphoric acid as a catalyst. Acetylation is completed in about fifteen minutes at ordinary temperatures. The process is not satisfactory for oil of citronella.—Sabatay, *C. R. Acad. Sci., Paris*, 1934, 199, 1419.

Identification of Phenols. Methods given for the identification of thymol, carvacrol, eugenol, iso-eugenol, and vanillin through the melting-points of the arylacetic acids.—Reed, *Perfum. essent. Oil Rec.*, 1933, 190.

The Determination of Solubilities. Report of Sub-Committee on Uniformity of Analytical Methods. The terms used to describe solubility are described.—*Analyst*, 1930, 386. The alcohols used in the solubility tests for volatile oils should comply with the sp. gr. limits—90%, 0.8334 to 0.8340; 80%, 0.8634 to 0.8640; 70%, 0.8896 to 0.8901.

Solubilities of perfumery ingredients, essential oils and synthetics in ethyl alcohol.—*Perfum. essent. Oil Rec.*, 1924, 283.

Essential oils are able to hold water in solution, particularly those which contain a large proportion of oxygenated bodies.—see Umney and Bunken, *Perfum. essent. Oil Rec.*, May, 1912.

Determination of Essential Oils in Solution in Alcohol. A volume of the sample containing about 200 mg. of oil (or 8 g. of sample if it contains less than 1% of oil) is weighed by difference into a 100 ml. separating funnel and shaken with 80 ml. of 30% ammonium sulphate solution. When the oil has separated the aqueous layer is poured through a small filter over which 1 g. of medicinal Norit carbon has been distributed, the separating funnel and filter being washed with two successive quantities, each of 5 ml., of the ammonium sulphate solution. The filtrate can be used for the determination of the alcohol after acidification with sulphuric acid. The filter and contents are then shaken in the separating funnel with 15 ml. of ether and sufficient anhydrous sodium sulphate to absorb the water and ethereal extract is poured through a small filter into a tared 150 ml. flask containing a weighed amount (about 0.5 g.) of liquid paraffin. The separating funnel and filter are washed five times using 5 ml. of ether each time, and the solvent is finally removed by distillation at not over 40°. The last traces are removed by a current of air and the residue is placed in a vacuum desiccator over calcium oxide until the difference in weight between two successive weighings does not exceed 1 to 2 mg.—H. J. Van Giffen, *Pharm. Weekbl.*, 1936, 641.

Rapid method of determination. The oil is extracted from the solution by means of petroleum ether, which is then evaporated in a special apparatus and the residue weighed; the alcohol is determined by distilling the extracted liquid and taking the specific gravity of the distillate.—G. A. Rosenberger, *Perfum. essent. Oil Rec.*, 1939, 133.

Determination of Volatile Oil in Drugs. The methods for the determination of essential oils in drugs involve the use of a continuous distillation apparatus in which the drug is distilled in steam and the condensed water, separated from the oil, is returned to the distilling flask, the amount of oil obtained being measured at the end of the operation. Considerable variation has often been found in the yields of oil from different samples of a drug, and it is desirable that minimum limits for the yield of the essential oil in such drugs should be fixed. A method for certain drugs is given in the *U.S.P. XII* and in *P.G. VI*. Apparatus and processes have also been described by J. F. Clevenger (*Perfum. essent. Oil Rec.*, 1928, 226), G. R. A. Short (*Quart. J. Pharm.*, 1931, 444), Cocking and Middleton (*ibid.*, 1932, 521, also 1935, 435), Kuhn (*Pharm. Ztg.*, 1934, 99, per *Quart. J. Pharm.*, 1934, 691), Horkeimer (*Quart. J. Pharm.*, 1935, 535), Kofler and Herrens-schwand (*ibid.*, 1936, 117), Wasecky, Graf and Bayer (*ibid.*, 1936, 308), Mijnhardt (*ibid.*, 1936, 572), Rom (*ibid.*, 1936, 701), H. J. Van Giffen (*ibid.*, 1938, 269), K. Koch (*ibid.*, 1939, 275),

L. Goldberg, R. K. Sugden, E. H. Wirth and F. N. Gathercoal (*J. Amer. pharm. Ass.*, 1938, 385).

The volatile oil contents of drugs and spices may be determined with apparatus in which the receiver is a standard separating funnel receiver (V. 4) as specified by the Standardisation of Tar-Products Tests Committee. Results are given for a number of substances including nutmeg, cinnamon, clove, caraway, cardamom and umbelliferous fruits.—C. E. Sage and H. R. Fleck, *Analyst*, 1934, 614.

The various methods which have been advocated are compared and details of design and use of an apparatus are described. Sources of error are discussed, including the loss of oil through grinding the material and loss of yield through the degree of comminution being insufficient to allow the oil to escape from the tissues. Figures are given comparing the powdered and unground drugs of commerce for a very large number of samples, also a table showing the yields obtained when the drugs were distilled whole and in varying degrees of comminution.—H. O. Meek and F. G. Salvin, *Quart. J. Pharm.*, 1937, 471.

Surface Tension of essential oils in dynes per centimetre at 20°.—*Perfum. essent. Oil Rec.*, 1935, 18.

Changes in Refractive Index with alteration in temperature. A table giving correction per 1°.—*Perfum. essent. Oil Rec.*, 1937, 95.

Detection of Traces of Metallic Contamination. The organic matter is first destroyed by oxidation with a mixture of sulphuric and nitric acids and a solution obtained. An aliquot part of this solution is used for the determination of the metal present. Methods are given for lead, copper, tin, iron, aluminium and zinc.—F. R. Nares, *Quart. J. Pharm.*, 1935, 255.

Absorption of Ultra-violet Light by Essential Oils. Absorption curves using ultra-violet light have been determined for a large number of essential oils. The curves can be used for identification, detection of adulteration and in certain cases for quantitative assay.—D. Van Os and K. Dykstra, *J. Pharm. Chim. Paris*, 1937, 25, 437, 485; per *Quart. J. Pharm.*, 1938, 122.

Chloramine Value. The number of mls. of N/100 chloramine solution used up by 0.05 g. of substance. It is found by dissolving less than 50 mg. of oil in glacial acetic acid, and adding an equal volume of N/5 chloramine solution in a four-fold excess of water. Stand one hour in the dark, add potassium iodide solution and titrate with sodium thiosulphate. The chloramine value often decreases with age. Values for a number of oils are given.—P. W. Danchwortt and J. Hotzel, per *Quart. J. Pharm.*, 1938, 285.

Diene Value. The diene value of an essential oil is the number of grammes of iodine equivalent to the maleic anhydride absorbed by 100 g. of the substance. The method involves the heating of a weighed amount of the substance with a measured volume of a standardised maleic anhydride solution in a suitable solvent in sealed tubes for a definite period followed by a volumetric determination of the maleic anhydride remaining unchanged. The diene value may prove of use in the detection of diluents foreign to particular oils.—T. F. West, *Perfum. essent. Oil Rec.*, 1940, 20.

TERPENELESS ESSENTIAL OILS

Essential oils from which the terpenes and sesquiterpenes have been separated by fractional distillation *in vacuo* have the advantage that they are stronger in perfume and flavour and more readily soluble in diluted alcohol than the original oils. Some oils, e.g., clove oil, contain so small a proportion of terpenes that there is generally no point in rendering them terpeneless. In other oils the proportion of the terpenes is so variable that the yield of terpeneless oil differs widely. With the exception of the citrus oils, which are prepared in both the terpeneless and sesquiterpeneless forms, the term terpeneless generally implies an oil which has been obtained by fractionation and is free from both terpenes and sesquiterpenes.

In a new method for the production of terpeneless oils advantage is taken of the selective solubility of two solvents, pentane for the terpenes and diluted methyl alcohol for the oxygenated bodies. The process is covered by patent.—van Dijck and Ruys, *Perfum. essent. Oil Rec.*, 1937, 91.

The following table is mostly derived from Durrans, *Perfum. essent. Oil Rec.*, 1924, 240, with revisions, 1929. In the original article a number of physical data are also given.

Terpeneless and Sesquiterpeneless Oils

| | Concentration | 1 vol. Oil soluble in Alcohol |
|--|---------------|--------------------------------|
| Absinthe | — | 2 to 3 vols. 70% |
| Angelica | 20 | 3 vols. 70% |
| Aniseed | 1.5 | 10 vols. 80% |
| Bay | 2—3 | 1—1.5 vols. 70% |
| Bergamot | 2.5—3 | 1 vol. 80%; 3—4 vols. 70% |
| Calamus | — | 25 vols. 60%; 3 vols. 70% |
| Cananga | 6 | 1 vol. 90% |
| Caraway | 2 | 2 vols. 70%; 19 vols. 50% |
| Cardamom | 2 | 2—3 vols. 70% |
| Cassia | 2 | 2 vols. 70% |
| Cedarwood | — | 1 vol. 90% |
| Celery | 8 | 2 vols. 80% |
| Cinnamon Leaf | 3 | 1 vol. 70%; 3 vols. 60% |
| Citronella (Ceylon) | 2 | 2 vols. 70% |
| Citronella (Java) | 1.5 | 2 vols. 70% |
| Clove | 1.5 | 2.5 vols. 60%; 1 vol. 70% |
| Coriander | 1.5 | 2 vols. 70% |
| Cumin | 1.5—2 | 5—7 vols. 70% |
| Dill | 2—3 | 2—3 vols. 70% |
| Eucalyptus Globulus | 2—3 | 2 vols. 70% |
| Fennel | 1.5 | 1 vol. 90% |
| Geranium | 1.5—2 | 1—2 vols. 70% |
| Ginger | 12 | 2—4 vols. 80% |
| Grape Fruit | 50 | 2 vols. 80% |
| Hops | 8 | 1 vol. 80%; 20—30 vols. 70% |
| Juniper Berry | 10 | 1 vol. 90% |
| Lavender (French) | 2 | 1—2 vols. 70% |
| Lemon | 25 | 3 vols. 70% |
| Lemongrass | 1.5 | 2 vols. 70% |
| Linaloe | 1.5 | 1.5—3 vols. 70% |
| Limes (Handpressed) | 6 | 2 vols. 70% |
| Limes (Distilled) | 15—20 | 1.5 vols. 70% |
| Mandarin Orange | 70 | 2.5—4 vols. 70%; 1.5 vols. 80% |
| Neroli | 2 | 2—2.5 vols. 70% |
| Nutmeg | 8 | 1 vol. 80%; 4 vols. 70% |
| Orange | 65 | 2—3 vols. 70% |
| Palmarosa | 1.5 | 2 vols. 70% |
| Parsley | 10 | 2 vols. 80% |
| Patchouli | 4 | 1 vol. 95% |
| Pennyroyal | 2 | 2 vols. 70% |
| Peppermint (American) | 2 | 3 vols. 70% |
| Peppermint (Jap. dementolised) | 2 | 2.5 vols. 70%; 6 vols. 60% |
| Peppermint (Mitcham) | 2 | 2.5—3 vols. 70% |
| Petitgrain | 2 | 1 vol. 80%; 3 vols. 70% |
| Pimento | 1.5 | 1 vol. 70% |
| Pinus Sibirica (Abies) | 2—3 | 3 vols. 70% |
| Rosemary (French) | 2 | 2—3 vols. 75% |
| Rose Otto (Stearopteneless) | 1.5—2 | 1—1.5 vols. 70% |
| Sage | 6 | 2—2.5 vols. 75% |
| Sandalwood | 1.5 | 3—5 vols. 70% |
| Sassafras | 2 | 1 vol. 90% |
| Spearmint | 4 | 2 vols. 75% |
| Spike Lavender | 2 | 2 vols. 70% |
| Spike (Spanish) | 1.5 | 2 vols. 70% |
| Thyme | 2—3 | 2—3 vols. 70% |
| Vetivert | 10 | 1 vol. 80% |
| Ylang (Manilla) | 4—5 | 1—1.5 vols. 90% |

ANTISEPTIC POWERS OF ESSENTIAL OILS

The antiseptic power of a number of essential oils was determined by W. H. Martindale, *Perfum. essent. Oil Rec.*, Nov., 1910. The *Lancet* carbolic acid coefficient using *B. Coli communis* was determined either in aqueous or in saponaceous solutions according to the solubility of the particular oil.

| Essential Oil | Carbolic acid co-efficient | Chief chemical constituents |
|---------------------------------|----------------------------|--|
| Origanum Oil (A) | 26 | 82% phenols, e.g., carvacrol. |
| Thymol (S) | 25 | |
| Carvacrol (S) | 21 | |
| Thymol (A) | 19 | |
| Thyme Oil (S) | 15 | 46% phenols (thymol, etc.). |
| Thyme Oil (A) | 13 | 46% phenols (thymol, etc.). |
| Geraniol (S) | 12 | |
| Cinnamon Leaf Oil (S) .. | 10 | 86% phenols, e.g., eugenol. |
| Cinnamon Bark Oil (S) .. | 9 | 52% aldehyde, e.g., cinnamic. |
| Clove Oil (S) | 9 | 90% phenols, e.g., eugenol. |
| Cinnamic Aldehyde (S) .. | 8 | |
| Citronellol (S) | 8 | |
| Cinnamon Bark Oil (S) .. | 8 | 82% aldehyde, e.g., cinnamic. |
| Cinnamon Bark Oil (A) .. | 7 | 82% aldehyde, e.g., cinnamic. |
| Rosemary Oil (S) | 6 | |
| Otto of Rose (S) | 6 | 68% alcohols estimated as geraniol. |
| Cassia Oil (S) | 5 | 83.5% aldehyde, e.g., cinnamic. |
| Wintergreen Oil (S) | 5 | Methyl salicylate. |
| Eucalyptus Amygd. (S) .. | 5 | Phellandrene and eucalyptol. |
| Lavender Oil (English) (S) .. | 5 | Esters as linalyl acetate, 11%. Other constituents of the oil are linalool as such, esters other than the acetate, cineole and limonene. |
| Lemon Oil (S) | 4 | Limonene, citral, 4 to 7% citronellal, geranyl acetate, possibly other esters of geraniol and citronellal. |
| Almond Oil, Ess. s.A.P. (S) .. | 4 | Benzaldehyde chiefly. |
| Eucalyptol (S) | 4 | |
| Eucalyptus Glob. Oil (S) .. | 4 | 67% eucalyptol together with pinene, phellandrene, alcohols and aldehydes. |
| Garlic Oil | 2 | Allyl sulphide chiefly. |
| Light Oil of Tar (Rect.) (S) .. | 2 | Volatile bodies. Contains no phenols. |
| Santal Oil (S) | 1½ | 93.8% alcohol calculated as santalol, $C_{16}H_{34}O$. |
| Birch Tar Oil (S) | 1½ | Stated to contain guaiacol, cresol and pyrocatechin. |
| Cade Oil (S) | 1 | |

(A) = Aqueous solution. (S) = Saponaceous solution.

These values have been confirmed and others added to the list by later investigators. The following are some of the more important references:—

Carbolic acid coefficients are given against a mixed culture of *Micrococcus catarrhalis* for a number of compounded perfumes. Isopropyl alcohol solutions have slightly greater bactericidal powers than ethyl alcohol solutions.—Dyche-Teague, *Perfum. essent. Oil Rec.*, 1924, 6, 40 and 181; see also Bryant, *ibid.*, 252.

Germicidal value of some Australian essential oils. Certain oils could be used in place of phenol or cresols as preservatives in antisera.—Penfold, *Perfum. essent. Oil Rec.*, 1924, 127.

Rideal-Walker Coefficients of Constituents of Essential Oils

The following list has been compiled from tables appended to an article on "An investigation into the germicidal powers and capillary activities of certain essential oils," by S. Rideal, E. K. Rideal and A. Sciver (*Perfum. essent. Oil Rec.*, 1928, 285).

| Substance | R.W. coeff. | Type | Remarks |
|--------------------------------|-------------|-----------------|--------------------------------|
| Acetophenone.. | 4 | Ketone .. | Synthetic. |
| Amyl salicylate .. | 4 | Ester .. | — |
| Amyl valerianate .. | 5 | Ester .. | — |
| Anethole .. | 11 | Ether .. | — |
| Anisaldehyde .. | 7 | Aldehyde .. | — |
| Anthranilic acid .. | 12 | Acid .. | In alcohol. |
| Aromadendrene .. | < 1 | Sesquiterpene.. | <i>E. nova-anglica.</i> |
| Australol .. | 22.5 | Phenol.. | <i>E. cneorifolia.</i> |
| Benzaldehyde.. | 9 | Aldehyde .. | Synthetic. |
| Benzyl acetate .. | 2 | Ester .. | — |
| Benzyl alcohol .. | 5.25 | Alcohol .. | — |
| Benzyl valerianate .. | 6 | Ester .. | — |
| Borneol .. | 15 | Alcohol .. | In alcohol. |
| Borneol .. | 10 | Alcohol .. | In soap solution. |
| Bornyl acetate .. | 6 | Ester .. | Synthetic. |
| Butyl valerianate .. | 10 | Ester .. | — |
| Camphor .. | 6 | Ketone .. | <i>Doryphora sassafras.</i> |
| Cineol .. | 3.5 | Oxide .. | <i>E. polybractea.</i> |
| Cinnamic aldehyde .. | 17 | Aldehyde .. | Synthetic. |
| Citral .. | 19.5 | Aldehyde .. | <i>E. Staigeriana.</i> |
| Citronellal .. | 13.5 | Aldehyde .. | <i>E. citriodora.</i> |
| Citronellol .. | 14 | Alcohol .. | Redn. of citronellal. |
| Citronellyl valerianate .. | 2 | Ester .. | Synthetic. |
| Coumarin .. | 4 | Lactone .. | — |
| Croweacin .. | 2 | Ether .. | <i>Eriostemon Croweii.</i> |
| Cryptal .. | 12 | Aldehyde .. | <i>E. cneorifolia.</i> |
| Cuminal .. | 12.75 | Aldehyde .. | <i>E. cneorifolia.</i> |
| Cymene .. | 8 | Hydrocarbon .. | Synthetic. |
| Darwinol .. | 13 | Alcohol .. | <i>Darwinia grandiflora.</i> |
| Darwinol acetate .. | 3 | Ester .. | <i>Darwinia grandiflora.</i> |
| Ethyl valerianate .. | 4.5 | Ester .. | Synthetic. |
| Eudesmol .. | < 1 | Sesquiterpene.. | <i>E. Moorei.</i> |
| Eugenol .. | 15 | Phenol .. | <i>Doryphora sassafras.</i> |
| Geraniol .. | 21 | Alcohol .. | Geranyl acetate. |
| Geranyl acetate .. | 0 | Ester .. | <i>E. Macarthuri.</i> |
| Geranyl valerianate .. | 2 | Ester .. | Synthetic. |
| Isoamyl alcohol .. | 2 | Alcohol .. | Synthetic. |
| Isobutyl alcohol .. | 2 | Alcohol .. | — |
| Isobutyl valerianate .. | 8.5 | Ester .. | — |
| Isomenthone .. | 14 | Ketone .. | Redn. of piperitone. |
| Isosafrol .. | 12 | Ether .. | Synthetic. |
| Isovaleraldehyde .. | 5 | Aldehyde .. | <i>E. Macarthuri.</i> |
| Limonene .. | 1 | Terpene .. | <i>E. Staigeriana.</i> |
| Linalyl acetate .. | 5.25 | Ester .. | Synthetic. |
| Linalool .. | 13 | Alcohol .. | <i>Geijera</i> species. |
| Menthol .. | 20 | Alcohol .. | All sources. |
| Menthyl .. | 19 | Alcohol .. | Old stock. |
| Menthone .. | 10 | Ketone .. | Redn. of piperitone. |
| Menthyl valerianate .. | 3 | Ester .. | Synthetic. |
| Methyl anthranilate .. | 6.5 | Ester .. | — |
| Methyl eugenol ether .. | 13.5 | Ether .. | — |
| Methyl salicylate .. | 5.5 | Ester .. | — |
| Ocimene .. | 3 | Olefine .. | <i>Homoranthus flavescens.</i> |
| Phellandral .. | 9.25 | Aldehyde .. | <i>E. cneorifolia.</i> |
| Phenyl ethyl valerianate .. | 4 | Ester .. | Synthetic. |
| <i>l</i> - α -Pinene .. | 1 | Terpene .. | <i>E. phlebophylla.</i> |

Rideal-Walker Coefficients of Constituents of Essential Oils (contd.)

| Substance | R.W. coeff. | Type | Remarks |
|-------------------------|-------------|-------------|-----------------------------|
| Piperitol | 13 | Alcohol .. | <i>E. radiata.</i> |
| Piperitone | 8 | Ketone .. | <i>E. dives.</i> |
| Piperitone | 8 | Ketone .. | Commercial 80%. |
| Piperonal | 3 | Aldehyde .. | Synthetic. |
| Propyl valerianate .. | 8 | Ester .. | — |
| Rhodinyl valerianate .. | 1 | Ester .. | — |
| Safrol | 11 | Ether .. | <i>Doryphora sassafras.</i> |
| Terpin hydrate | 1 | — .. | Pinene. |
| Terpineol | 7.5 | Alcohol .. | <i>E. australiana.</i> |
| α -Thujone | 12 | Ketone .. | <i>Boronia thujona.</i> |
| Thymol | 25 | Phenol .. | Ajowan or piperitone. |
| Valerianic acid | 2 | Acid .. | Synthetic. |
| Vanillin | 3.5 | Aldehyde .. | — |
| Xylene musk | 4 | — .. | — |

Rideal-Walker Coefficients of Essential Oils

| Oil | Rideal-Walker coefficient |
|-----------------------------|---------------------------|
| Bay | 5.5 |
| Bois de Rose | 5.4 |
| Cajuput | 1.0 |
| Cassia | 1.4 |
| Cedarwood | 1.6 |
| Ceylon Citronella | 2.0 |
| Cinnamon Leaf | 7.5 |
| Cloves | 8.0 |
| Coriander | 5.4 |
| Eucalyptus | 1.6 |
| Japanese Mint (Dementh.) .. | 0.7 |
| Java Citronella | 2.2 |
| Juniper Berry | Less than 0.1 |
| Kananga | Less than 0.1 |
| Lavender | 1.6 |
| Lemon | 0.4 |
| Orange | 0.4 |
| Palmarosa | 9.0 |
| Patchouli | 1.6 |
| Sassafras | 0.6 |
| Spearmint | 2.8 |
| Spike Lavender | 1.6 |
| Star Aniseed | 0.4 |
| Sweet Birch | 0.4 |
| White Camphor | 0.4 |
| Wormseed | 1.0 |

—S. Rideal, E. K. Rideal and A. Sciver, *Perfum. essent. Oil Rec.*, 1928, 285.

The vapours of some essential oils have disinfecting activity with selectivity towards acid-fast bacteria.—Otto Schöbl, *Philipp. J. Sci.*, 1924, 443, per *Perfum. essent. Oil Rec.*, 1924, 330.

Oils of high carboic acid coefficient are more likely to lower surface tension.—E. K. Rideal, S. Rideal and A. Sciver, *Perfum. essent. Oil Rec.* 1928, 235.

Physiological aspects of essential oils in relation to constitution. A table is given of Rideal-Walker coefficients for a large number of constituents of essential oils.—Malcolm Dyson, *Perfum. essent. Oil Rec.*, 1930, 287.

Germicidal values of commercial eucalyptus oils. The cineole-containing oils have not the highest antiseptic value.—Penfold, *Bull. tech. Mus., Sydney*, 1933, No. 2; also *Perfum. essent. Oil Rec.*, 1935, 130.

Ti-tree oil has been introduced and recommended for its bactericidal properties. Numerous articles have appeared on its composition and use, see *Perfum. essent. Oil Rec.*, 1929, 155; *Mfg Chem.*, 1936, 332; *Chem. & Drugg.*, 1936, 524; *Pharm. J.*, 1936, 632. See also p. 268.

Antiseptic Power of Essential Oils. The addition of certain fixative substances increased the time during which oils are effective.—Risler, *Quart. J., Pharm.*, 1937, 152.

The use of *Bact. typhosum* as the sole test organism in the Rideal-Walker test is shown to be unreliable for comparing the relative efficiencies of germicidal preparations containing essential oils such as pine-oil or titree oil, or combinations of these oils with chlorinated phenols, particularly where the preparations are to be used at considerable dilution for the purposes of skin disinfection or application to wounds. It is doubtful if a more suitable test organism than *Staph. aureus* can be obtained since, besides being one of the normal skin flora, it is the most resistant of the non-spore-forming pathogens.—Q. Moore and J. N. Walker, *Pharm. J.*, ii/1939, 507.

A study of the penetration power of antiseptics using a modification of the Reddish cup method for volatile substances shows that the inorganic acids and bases in general exhibit high penetration, the organic acids, picric, salicylic, benzoic and others, show slight penetration values. Organic preparations have variable penetration values; acriflavine, gentian violet and safranin show small penetration. The ointments in general show slight penetration values. Essential oils exhibit a wide variation of values; oils of bitter almonds and mustard show the highest values; oils of cinnamon, turpentine and thyme and eucalyptol show medium values; oils of cloves, eucalyptus, lavender, lemon, caraway, pimento and rosemary give values somewhat higher than 5% PhOH which has a penetration value of 5 mm.—L. J. Piccoli and Morris Hecht, *J. Amer. pharm. Ass.*, 1939, 157-62.

Report on twenty-two essential oil-bearing materials and seventeen pure oils. The pH and bacterial count examined over a period of eight days. Infusions of fennel, marjoram, juniper berry, galangal and orris root possess some bactericidal power.—H. Kliewe and E. K. Huthmacher, *Perfum. essent. Oil Rec.*, 1939, 61.

NOTES ON INDIVIDUAL ESSENTIAL OILS

For notes on essential oils not included in the following group, see under the corresponding drug, e.g., notes on *Oleum Caryophylli* are included under *Caryophyllum*.

OLEUM ABIETIS

Oleum Abietis (*B.P. Add. I*). Contains 33 to 45% w/w of esters, calculated as bornyl acetate, $C_{19}H_{30}O_2$. Sp. gr., 0.905 to 0.925. α_D , -32° to -45° . n_{D20} , 1.466 to 1.476. Soluble in an equal volume of alcohol (90%). Assayed by the *B.P.* method for esters, by saponification of 2 g. of the neutralised oil with 40 ml. of N/2 alcoholic potash during one hour on a water-bath.

The following limits are recommended for the Tyrolean oil of *Abies alba*:—sp. gr. at 15° , 0.867 to 0.880; optical rotation, -13° to -67° ; refractive index at 20° , 1.4729 to 1.4760; ester content (calculated as bornyl acetate) up to 11%; solubility at 20° , 1 in 4 to 10 volumes of alcohol 90%, sometimes with slight turbidity. Since as much as 55% and more distils below 170° , any definite

figure would be meaningless.—C. H. Grimm, E. E. Langenau and E. S. Guenther, *J. Amer. pharm. Ass., Sci. Edn.*, 1941, 209.

In addition to oil of Siberian fir, there are several **pine-needle oils** of commercial importance. Oil of *Pinus sylvestris* has very variable characters according to the locality in which it is produced. Oil of *Pinus pumilio* was official in the B.P. '98; it is mainly produced in the Tyrol.

An account of the process for the production of resin and volatile oils. A fraction of the volatile oil is sold as steam-distilled pine oil which contains a high proportion of alcohols, mostly α -terpineol.—*Chemical Age*, 1938, 39, 387.

Yields of pine-needle oils from various species of Abietineæ.—Willner, *Quart. J. Pharm.*, 1933, 253.

ABIETIC ACID derivatives and decomposition products.—*J. chem. Soc. Abstr.*, i/1920, 232.

OLEUM AURANTII

Oleum Aurantii (B.P.C.). Residue on evaporation 2 to 4% w/w; sp. gr., 0.848 to 0.852 (sweet orange) or 0.852 to 0.856 (bitter orange). α_D , +95° to +99° (sweet orange) or +88° to +96° (bitter orange). n_{D20} , 1.472 to 1.474 (sweet orange) or 1.472 to 1.475 (bitter orange). The first 10% of the distilled oil has an optical rotation the same or only slightly lower than the original oil. Oleum Aurantii, U.S.P. XII, is derived from fresh peel of the sweet orange only; sp. gr., 0.842 to 0.846 at 25°; α_D , +94° to +99° at 25°; n_{D20} , 1.4723 to 1.4737. Residue on evaporation not above 100°, not less than 1.7%. The first 10% of the distilled oil has an optical rotation the same or not more than 2° away from that of the original oil and a refractive index from 0.0008 to 0.0015 lower at 20°. Oleum Aurantii Amari, N.F. VII, has a sp. gr. at 25° of 0.845 to 0.851; α_D at 25°, +88° to +98°; the first 12% of the distilled oil has an optical rotation not more than 2° lower or more than 4° higher than the original oil.

The difference between bitter and sweet orange oils is not greater than the variations of analytical characters, flavour and odour so that they cannot be distinguished. **Tangerine orange** oil differs greatly from orange oil in flavour and aroma; it contains methyl anthranilate and methyl methylantranilate, and yields a distinctive terpeneless oil.

The principal varieties of orange oil commercially are Sicilian, West Indian, Californian, and recently S. African. The last two show a low residue on evaporation.

South African orange oil. Yield of oil and physical data.—*Perfum. essent. Oil Rec.*, 1930, 111.

Composition of Californian orange and lemon oils. A very complete report with methods of analysis and tabulated results.—Poore, U.S. Dept. of Agriculture, Tech. Bull. No. 241, per *Perfum. essent. Oil Rec.*, 1932, 166.

Residue on evaporation and other data.—C. T. Bennett, *Perfum. essent. Oil Rec.*, 1932, 2.

The appearance under ultraviolet light of the oils of mandarin, sweet orange, bergamot and lemon; undiluted and in alcoholic solution of 0.17% and 0.0034% showed marked differences particularly in the undiluted oils. Spots on porcelain of the undiluted oils showing mandarin, purple; sweet orange, mustard yellow; bergamot, greenish yellow, purple halo; lemon, deep greenish yellow, violet halo. An abstract of the original paper of E. Bottini in *Annali della Sperimentazione Agraria*, appears in *Perfum. essent. Oil Rec.*, 1935, 85.

Terpeneless Oil of Sweet Orange. Berte (*Yearb. Pharm.*, 1924, 102) gives yield of terpeneless oil as 1.5% and the following figures:—Sp. gr., 0.883 to 0.900; α_D , +25° 50' to +42° 20'; aldehydes as citral, 25% to 43%; esters as linalyl acetate, 14.8%. The sp. gr. is sometimes higher, up to 0.915.

A note from Sicily says the process of manufacture is exactly similar to that for terpeness lemon oil, q.v., except that a larger quantity of terpenes are distilled off—about 95%. No physical or chemical data are known for the finished product, as it is only very rarely distilled, and then it is not a great success. The odour of the terpeness orange oil does not pay for the distillation in many cases. The terpeness orange oils on the market are usually "synthetic" products, i.e., a mixture of which the chief odoriferous constituent is methyl methylantranilate. The distillation in London and elsewhere is carried out more scientifically than in Southern Italy.

OLEUM BERGAMOTTÆ

Oleum Bergamottæ (B.P.C.). Contains not less than 36% of esters, calculated as linalyl acetate, $C_{12}H_{20}O_2$. Sp. gr., 0.882 to 0.886; α_D , +12° to +24°; n_{D20° , 1.464 to 1.467. Residue on evaporation, 4 to 5% w/w, and the residue has an acid value of 20 to 50, and saponification value of 160 to 200. Complies with tests for absence of certain artificial esters, terpinyl acetate, and glyceryl acetate. *Oleum Bergamottæ, N.F. VII*, contains not less than 36% of ester, as linalyl acetate; sp. gr., 0.875 to 0.880 at 25°; α_D at 25°, +8° to +24°. Tests for fixed oils and for chlorinated compounds are included.

Determination of adulteration with terpinyl acetate.—Schimmel's Reports, 1911, 116, per *Yearb. Pharm.*, 1912, 75. Advantage is taken of the fact that terpinyl acetate is much less readily saponified than linalyl acetate.

Appearance under ultra-violet light.—See notes under *Oleum Aurantii*.

OLEUM CAJUPUTI

Oleum Cajuputi (B.P.). Contains 50 to 60% w/w of cineole, $C_{10}H_{18}O$. Sp. gr., 0.916 to 0.926. α_D , not greater than -4°. n_{D20° , 1.462 to 1.472. Soluble in 2 volumes of alcohol (80%). Assayed by determination of the freezing-point of a mixture of 3 g. of the oil and 2.1 g. of *o*-cresol, the freezing-point being between 27.4° and 35.1°. The *B.P. Add. I* alters the standard for cineole content and the refractive index—cineole content, 50 to 65% w/w; n_{D20° , 1.464 to 1.472. *Oleum Cajuputi, U.S.P. X*, should be soluble in 1 volume of 80% alcohol; sp. gr., 0.912 to 0.925 at 25°; n_{D20° , 1.4660 to 1.4710. *Oleum Cajuputi, P. Helv. V*, contains 45 to 70% of cineole; assayed by crystallising, by cooling in ice water for 30 minutes, 2.5 g. with 2.5 g. eucalyptol and 10 ml. of 50% resorcinol solution, separating the crystals, decomposing by warming with dilute sodium hydroxide solution and measuring the volume of cineole.

This is now required to be rectified, a process which increases the proportion of cineole. The upper limit of 60% for cineole is too low and excludes many high quality oils. The limit should be raised to 65%.—C. T. Bennett, T. T. Cocking and W. H. Simmons, *Pharm. J.*, ii/1933, 581.

OLEUM CEDRI

Oleum Cedri (B.P.C.). Sp. gr., 0.941 to 0.950; α_D , -25° to -46°; n_{D20° , 1.495 to 1.510. *Oleum Cedri Folii, U.S.P. XII*,

assayed by interaction with hydroxylamine hydrochloride, contains not less than 60% thujone, $C_{10}H_{16}O$. Sp. gr., 0.910 to 0.920 at 25°; α_D at 25°, -10° to -13° ; n_{D20° , 1.4560 to 1.4590.

EAST AFRICAN CEDARWOOD OIL, from *Juniperus procera*, has an odour similar to that of American cedarwood oil, but the optical rotation is higher.—*Bull. Imp. inst. Lond.*, 1931, 29, 430; per *Quart. J. Pharm.*, 1932, 101.

MICROSCOPICAL CEDARWOOD OIL for use with immersion objectives and condensers, is a specially prepared oil, more viscous than the ordinary, and with refractive index adjusted to a definite figure. The oil to be used as a clearing agent in microscopy is the ordinary variety.

OLEUM CHENOPODII

Oleum Chenopodii (B.P. Add. I). Contains not less than 65% w/w of ascaridole, $C_{10}H_{16}O_2$. Sp. gr., 0.962 to 0.983; α_D , -4° to -8° ; n_{D20° , 1.474 to 1.479. Assayed by titration of the iodine liberated when an acetic acid (90%) dilution of the oil is allowed to interact for 5 minutes with a potassium iodide solution, hydrochloric acid and glacial acetic acid at -3° ; a blank titration is conducted, diluting with water before titration (see T. T. Cocking and Hymas, *Quart. J. Pharm.*, 1930, 253). The U.S.P. XII assays by a similar method and requires the same ascaridole content. Sp. gr., 0.950 to 0.980 at 25°; n_{D20° , 1.4740 to 1.4790. Essence de Chénopode Vermifuge, *Fr. Cx.* 1937, contains not less than 60% ascaridole.

A statistical study of the physical constants of 39 samples of the oil. Ascaridole is in direct relationship to the sp. gr. and in inverse relationship to the solubility in alcohol (70%).—J. C. Munch and W. F. Reindollar, *J. Amer. pharm. Ass.*, 1931, 564.

Determination of Ascaridole. The following method depends upon the liberation of iodine by ascaridole from a strongly acidified solution of potassium iodide. The reaction is complex and conditions must be carefully controlled. About 2.5 g. of the oil is weighed in a 50 ml. graduated flask which is then filled to the mark with 90% acetic acid, and some of this solution is placed in a narrow bore burette graduated in 20ths of a ml. and capable of being read to 0.01 ml. The stopcock should be such that it is possible to run out 5 ml. in not more than 5 seconds. Into a stoppered tube (150 mm. long and 25 mm. diameter) place 3 ml. of 5N potassium iodide solution, 10 ml. of glacial acetic acid and 5 ml. of hydrochloric acid. Stopper the tube and cool to -3° in a freezing mixture, then run in from the burette, as rapidly as possible, 5 ml. of the acetic acid solution of the oil; replace the stopper, mix the contents and allow to stand in a cool place for 5 minutes during which the temperature of the contents will rise but must not exceed 10° . After allowing about 2 minutes for the walls of the burette to drain completely note the volume run out. After the tube has been allowed to stand for 5 minutes titrate directly with N/10 sodium thiosulphate without the addition of starch. Conduct a blank determination in the same way but diluting the mixture with 20 ml. of water before titrating with thiosulphate, and deduct the volume used from the amount used in the titration. Each ml. of N/10 sodium thiosulphate is equivalent to 0.00665 g. of ascaridole.—Report of the Essential Oils Sub-Committee to the Analytical Methods Committee, *Analyst*, 1936, 179.

A tentative method for the determination of ascaridole in oil of chenopodium is described in *Methods of Analysis (A.O.A.C., 1940, 625)*. 10 ml. of a 1% dilution in 95% alcohol and 50 ml. of a titanous chloride solution are boiled for 2 minutes in a flask fitted with a bunsen valve and back titrated with standard ferric ammonium sulphate solution using ammonium thiocyanate indicator (1 g. ascaridole is reduced by 1.284 g. of $TiCl_3$).

A comparative study of the three recognised assays for oil of chenopodium. The methods of the *A.O.A.C.*, the *B.P.* and the *U.S.P.* are compared. The first two determine ascaridole, while the last measures the acetic-acid soluble fraction. The author finds that the two former methods yield results concordant with each other, but at variance with those obtained by the *U.S.P.* method.—W. F. Reindollar, *J. Amer. pharm. Ass.*, 1939, 589.

OLEUM CITRONELLÆ

Oleum Citronellæ (*B.P.C.*). Estimated by the *B.P.* method for alcohols, which consists of determination of the ester values of the acetylated oil and of the original oil and calculation from a formula, it contains not less than 57% (for the Ceylon oil) or not less than 85% (for the Java oil) by weight of total acetylisable constituents calculated as geraniol. Sp. gr., 0.897 to 0.912 (Ceylon) or 0.885 to 0.900 (Java); α_D , -6° to -14° (Ceylon) or -2° to -5° (Java); n_{D20} , 1.479 to 1.485 (Ceylon) or 1.468 to 1.473 (Java). Yields a clear or slightly opalescent solution with 10 parts of alcohol (80%) and no globules separate after 24 hours at a temperature not lower than 15.55° .

Examination of Citronella Oil. A method is given for the estimation of geraniol in the presence of citronellal. The oil is oxidized by the method of Dupont and Labaune, the N determined by the Kjeldahl method giving the citronellal; another portion of the oxidized oil is acetylated and the geraniol content found. Oils from Java, Celebes and Sumatra were examined.—Reclaire and Spoelstra, *Perfum. essent. Oil Rec.*, 1927, 130.

Determination of citronellal by means of hydroxylamine hydrochloride used at a low temperature.—*Analyst*, 1932, 773.

Formylation method shown to be unreliable.—C. T. Bennett, *Perfum. essent. Oil Rec.*, 1921, 351.

Alcohol as an adulterant.—E. J. Parry, *Chem. & Drugg.*, ii/1923, 390.

Determination of aldehydes. For a method of avoiding the difficulty caused by the insolubility of the citronellal sulphonate, as occurs in the usual bisulphite method, see F. D. Dodge, *Amer. Perfum.*, 1929, 24, 11; per *Quart. J. Pharm.*, 1929, 328.

OLEUM EUCALYPTI

Oleum Eucalypti (*B.P.*). By the freezing-point method of the *B.P.* as used for eucalyptol, oil of eucalyptus contains not less than 70% w/w of cineole. Sp. gr., 0.910 to 0.930; α_D , -5° to $+5^\circ$; n_{D20} , 1.458 to 1.470. Soluble in 5 volumes of alcohol (70%, sp. gr. 0.8896 to 0.8901). The *U.S.P. XII* requires the congealing point of Oleum Eucalypti to fall not below -15.4° , corresponding to not less than 70% of eucalyptol. Essence d'Eucalyptus, *Fr. Cx.* 1937, contains not less than 80% of eucalyptol. Oleum Eucalypti, *P. Helv. V*, determined by crystallisation of 5 ml. of the oil and 10 ml. of a 50% solution of resorcinol, decomposition of the separated crystals with sodium hydroxide solution and measurement of the cineole, contains 80 to 85% of cineole.

Eucalyptol (*B.P.*). $C_{10}H_{18}O=154.1$. By determination of the f.p. of a mixture of 3 g. of the dried substance and 2.1 g. of *o*-cresol,

a content of not less than 97.5% *w/w* of cineole, $C_{10}H_{18}O$, should be indicated. Sp. gr., 0.928 to 0.930; α_D , -1° to $+1^\circ$; n_{D20}^{20} , 1.456 to 1.460. F.p., not below 0° . Eucalyptol, *U.S.P. XII*, distills between 174° and 177° ; α_D at 25° , not more than $\pm 3^\circ$; n_{D20}^{20} , 1.4550 to 1.4600. Complies with tests for phenols.

Commercial Eucalyptus Oils. There are about ten eucalyptus oils met with in commerce, of which about seven are common. Their composition is very variable.

| Species | Principal Constituents |
|--|---|
| <i>E. polybractea</i> | Cineole (77 to 84%), pinene. |
| <i>E. dives</i> (type) | Piperitone (40 to 50%), phellandrene. |
| <i>E. phellandra</i> (<i>amygdalina</i>) | Cineole (20 to 35%), pinene, terpineol, phellandrene. |
| <i>E. Australiana</i> | Cineole (68 to 72%), pinene, terpineol. |
| <i>E. elaeophora</i> | Cineole (65 to 76%), pinene. |
| <i>E. sideroxylon</i> | |
| <i>E. leucoxylon</i> | |
| <i>E. citriodora</i> | |
| <i>E. Cneorifolia</i> | |
| <i>E. dives</i> var. "C" | Citronellal (70 to 85%). |
| <i>E. Macarthuri</i> | Cineole (69 to 73%), and terpenes. |
| | Cineole (60 to 75%), terpineol and terpenes. |
| | Geranyl acetate (60 to 72%), geraniol, eudesmol. |
| <i>E. radiata</i> | Phellandrene in abundance, and piperitol. |
| <i>E. Considemiana</i> | Cineole (50 to 70%), pinene, phellandrene. |
| <i>E. phlebophylla</i> | Pinene and eudesmol. |

Short monographs on the above are included, giving source, physical constants and composition. The oil of *E. Australiana* is sold in two fractions as "first hour oil" and "second hour oil." The former, which is the first oil obtained in the distillation, contains 70 to 82% of cineole, the latter contains only 25 to 40%. The author states that the oil has "no superior in aroma, flavour, etc., and is undoubtedly the finest eucalyptus oil for medicinal purposes." The oil of *E. phellandra* is also collected and sold as "first" and "second hour" oils. Methods for the determination of cineole by Kleber and von Rechenberg's process and by the ortho-cresol method, as given in the report of the Essential Oil Sub-Committee on Uniformity of Analytical Methods (*Analyst*, 1927, 276), were found to give close agreement. A qualitative and also a quantitative test for piperitone in *E. dives* oil is given, and also a quantitative test for citronellal in *E. citriodora* oil, and for the esters in *E. Macarthuri* oil.—A. R. Penfold, *Bull. tech. Mus., Sydney*, No. 2.

A number of physiological forms of *E. dives* exists yielding oils of widely different kinds:—

| Oil | Piperitone | Cineole | Phellandrene |
|------------------------|--------------|-----------|--------------|
| <i>E. dives</i> (type) | 46 to 53% | absent | present |
| " var. "A" | about 5% | | " |
| " var. "B" | 10 to 20% | 25 to 45% | " |
| " var. "C" | less than 5% | 60 to 75% | absent |

—*J. roy. Soc., N.S.W.*, 1929, 61, 54.

A very complete description of the eucalypts, in which over 170 species are examined, is given in "A Research on the Eucalypts especially in regard to their Essential Oils," by R. T. Baker and H. G. Smith, *Bull. tech. Mus., Sydney*, No. 24.

The physical and chemical constants for the oil of *Eucalyptus Australiana* are sp. gr., $15^\circ/15^\circ$, 0.9078; α_D , -11° ; n_{D20}^{20} , 1.4696. Solubility in 70% alcohol (by weight), 1.3 vols.; cineole, 50%; phellandrene, present in quantity; saponification no., 7.2; saponification no. after acetylation, 65.3.—A. R. Penfold and F. R. Morrison, *Perfum. essent. Oil Rec.*, 1936, 18.

Optically pure *l*- α -phellandrene has been prepared having sp. gr. 0.8324, refractive index 1.4724, and specific rotation 177.4 , all taken at 20° .—Hancock and Jones, per *Chem. & Drugg.*, i/1940, 215.

The *Rideal-Walker coefficients* of the principal eucalyptus oils.

The following tables appear in an article on "An investigation into the germicidal powers and capillary activities of certain Essential Oils," by S. Rideal, E. K. Rideal and A. Sciver (*Perfum. essent. Oil Rec.*, 1928, 285).

COMMERCIAL EUCALYPTUS OILS

| Crude Oil | R.-W. Co- effi- cients | Active Constituents | |
|--------------------------|---------------------------------|--|--|
| | | Principal | Minor |
| <i>E. polybractea</i> .. | 5 | Cineole 85% .. | Small amounts of the aromatic aldehydes. |
| <i>E. australiana</i> .. | 5 | Cineole 62% .. | Terpineol, geraniol, citral. |
| <i>E. dives</i> .. | 8 | Piperitone 52% .. | Piperitol. |
| <i>E. radiata</i> .. | 10 | Piperitol 20% .. | Piperitone. |
| <i>E. citriodora</i> .. | 8 | Citronellal 90% .. | |
| <i>E. cneorifolia</i> .. | 7.5 | Cineole 50% .. | Australol, cymene, aromatic aldehydes. |
| <i>E. phellandra</i> .. | 6 | Cineole 50% .. | Piperitone? |
| <i>E. Staigeriana</i> .. | 11 | Citral .. | Unidentified alcohol. |
| <i>E. Macarthuri</i> .. | 1 | Geranyl acetate 75% .. | Geraniol. |
| <i>E. hemiphloia</i> .. | 7 | Cymene, aromatic aldehydes, australol. | |

PURE CONSTITUENTS (FRESHLY PREPARED) OF EUCALYPTUS OILS

| Constituent | Nature | Source | R.-W. Coeffi- cients |
|--------------------------------|--------------------------|--|----------------------------|

| Piperitone 90% (commercial) .. | ketone .. | <i>E. dives</i> .. | 8 |
| Australol .. | phenol .. | <i>E. cneorifolia</i> .. | 22.5 |

OLEUM GERANII

Oleum Geranii (B.P.C.). Contains not less than 21% of ester, calculated as geranyl tiglate, $C_{15}H_{24}O_2$. Sp. gr., 0.895 to 0.905 (French) or 0.894 to 0.904 (Algerian) or 0.888 to 0.896 (Bourbon); α_D , -7° to -11° (French), or -7° to -12° (Algerian) or -8° to -14° (Bourbon); n_{D20}° , 1.465 to 1.470 (French) or 1.465 to 1.467 (Algerian) or 1.462 to 1.467 (Bourbon). Soluble in 3 volumes of alcohol (70%).

Geranium oil from S. Africa. Analytical characters given.—*Perfum. essent. Oil Rec.*, 1931, 102

For the method of cultivation of geraniums for essential oil, see *Perfum. essent. Oil Rec.*, 1932, 173.

Experimental cultivation in Calabria. Yields of oil given.—*Perfum. essent. Oil Rec.*, 1934, 9.

Oil which compares favourably with standard types of commercial geranium oil has been produced in Kenya from varieties of *Pelargonium*. The characters and analytical data are fully reported in *Bull. imp. Inst., Lond.*, 1934, 196.

OLEUM GRAMINIS CITRATI

Oleum Graminis Citrati (B.P.C.). Assayed by the B.P. method for aldehydes in Oleum Cinnamomi, by interaction of the neutralised oil in benzene solution with hydroxylamine reagent and titration with N/2 potash in alcohol (60%), it should contain not less than 75% w/w of citral, $C_{10}H_{16}O$. Sp. gr., 0.895 to 0.908; α_D , -4° to $+1^\circ$; n_{D20}° , 1.483 to 1.489. Soluble in 3 volumes of alcohol (70%), sometimes appearing opalescent in 10 volumes.

The oil is usually sold on its citral content and used for the preparation of citral. It should not be confused with true verbena oil which is obtained from *Lippia citriodora* (Fam. Verbenaceæ) and contains citral but is of much more delicate odour.

Spanish verbena oil is obtained from *Thymus hyemalis* (Fam. Labiatae).—*Perfum. essent. Oil Rec.*, 1912, 212.

OLEUM JUNIPERI

Oleum Juniperi (B.P.C.). Sp. gr., 0.870 to 0.890 (English) and 0.865 to 0.895 (Hungarian); α_D , $+1^\circ$ to -10° (English) and -5° to -15° (Hungarian); n_{D20}° , 1.476 to 1.479 (English) and 1.479 to 1.484 (Hungarian). Oleum Juniperi, U.S.P. XII, has a sp. gr. at 25° of 0.854 to 0.879; α_D at 25° , 0° to -15° and n_{D20}° , 1.4740 to 1.4840.

Continental juniper berry oils are very variable in quality, probably due to their being by-products in the manufacture of other preparations. Italian oil is generally considered the best Continental oil.

English juniper berry oil is pre-eminently superior.—*Perfum. essent. Oil Rec.*, 1915, 63.

The effect of age on the oil is to increase its specific gravity and render it less soluble.—*Perfum. essent. Oil Rec.*, 1914, 5.

The Continental oil known as juniper wood oil is composed very largely of terpenes and has very little true juniper odour.

OLEUM LAVANDULÆ

Oleum Lavandulæ (*B.P. Add. I*). Is obtained from *Lavandula officinalis* Chaix and contains 7 to 12% *w/w* (English) or not less than 35% *w/w* (foreign) of esters calculated as linalyl acetate, $C_{12}H_{20}O_2$. Sp. gr., 0.882 to 0.900 (English) or 0.883 to 0.895 (foreign); α_D , -3° to -10° (English and foreign oils); n_{D20° , 1.459 to 1.470 (English) or 1.459 to 1.464 (foreign). Soluble with not more than a slight opalescence in 4 volumes of alcohol (70%). Determined by saponification of the esters by the *B.P.* method. The *U.S.P. XII* requires Oleum Lavandulæ to contain not less than 30% of esters as linalyl acetate; sp. gr. at 25° , 0.875 to 0.888; α_D at 25° , -3° to -10° ; n_{D20° , 1.4590 to 1.4700. The volume of the oil should not diminish when shaken with water, a diminution indicating alcohol; a limit test for acetins is described by saponification of the alcohol (5%) solution.

Continental lavender oil differs from English oil in having a much higher ester content. The proportion of esters in Continental oil, 25 to 60%, is very variable, depending on locality, cultivation, method of distillation and other factors. The esters in English oil vary from 7 to 14%, depending on season.

For discussion on the identity of the linalyl esters, see Dalton, *Perfum. essent. Oil Rec.*, 1926, 432; Langlais and Goby, *Perfum. essent. Oil Rec.*, 1926, 520; and *Perfum. essent. Oil Rec.*, 1927, 47; also Parry, *Perfum. essent. Oil Rec.*, 1927, 8.

English lavender oil comes intermediate between French and spike oils in cineole content.—Cocking, *Perfum. essent. Oil Rec.*, 1921, 339.

The figure obtained by the ortho-cresol method is not a true estimate of the cineole in oils that contain esters, and this method is not applicable to the estimation of cineole in French lavender oil.—Reed, *Perfum. essent. Oil Rec.*, 1932, 340.

Oleum Lavandulæ Spicatæ (*B.P.C.*). Is obtained from *Lavandula latifolia* Vill. and contains, when determined by the *B.P.* method for free alcohols, not less than 30% of free alcohols calculated as linalol. Sp. gr., 0.900 to 0.920; α_D , -4° to $+6^\circ$; n_{D20° , 1.462 to 1.469. Soluble in three volumes of alcohol (70%) and six volumes of alcohol (65%).

The quality of Spanish spike lavender oil is affected by the method of distillation. Steam distillation yields an oil of lower solubility but of superior odour to that obtained by open-fire distillation. According to Bordas (*Perfum. essent. Oil Rec.*, 1927, 129) the open-fire method of distillation is almost universally employed in Spain, because the apparatus for steam distillation cannot be taken to the hills where the process is carried out. It is stated that though the physical data are important the odour of the oil is the criterion of quality, and that the range for the sp. gr. is 0.898 to 0.910.

Sage (*Perfum. essent. Oil Rec.*, 1927, 45) gives as a guide for Spanish spike oil the following figures:—Sp. gr. at 15.5° , 0.900 to 0.915; α_D at 25° , -5° to -10° ; n_{D20° , 1.464 to 1.466; solubility in 70% alcohol, 1 in 1.5 to 1 in 2.5; esters as linalyl acetate, 3 to 7%; total acetylisable, not less than 30%. See also Sage, *Perfum. essent. Oil Rec.*, 1923, 228, "An Analytical Symposium of the Spanish Essential Oils." French spike lavender oil differs very little from Spanish.

Lavandin Oil. In the districts of S. France where lavender and spike grow side by side, hybrids are formed from which lavandin oil is obtained on distillation. This oil is intermediate in odour value between true lavender and spike. It is generally sold on an ester content of 25%.

OLEUM LIMONIS

Oleum Limonis (*B.P. Add. I*). Contains not less than 4% *w/w* of aldehydes calculated as citral, $C_{10}H_{16}O$. Sp. gr.,

0.857 to 0.861; α_D , +57° to 65°; n_{D20° , 1.474 to 1.476. Limit of non-volatile residue, determined under specified conditions, of 2 to 3% w/w. The U.S.P. XII oil has a sp. gr. at 25° of 0.849 to 0.855; α_D at 25°, +57° to +65.6°; n_{D20° , 1.4742 to 1.4755. The first 10% of the distilled oil has a α_D not more than 5° less than that of the original oil and n_{D20° , 0.0010 to 0.0027 lower. Oleum Citri, *P. Helv. V*, assayed by addition of hydroxylamine hydrochloride solution neutralised to bromophenol blue, and titration with N/2 alcoholic potash, contains not less than 3.5% of citral. The *P.G. VI* requires the oil to be soluble clearly 1 in 12 in alcohol 90%, or to show only a little fluorescent matter, and to be free from fatty oils and paraffin.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined oil of lemon for food purposes as the volatile oil expressed, without the aid of heat, from the fresh peel of the lemon (*Citrus limonia* Osbeck) with or without previous separation of pulp and peel. *Terpeneless oil of lemon*: oil of lemon from which all or nearly all the terpenes have been removed.—*S.R.A., F.D. No. 2, Rev. 5, Nov., 1936*.

Oil of lemon is obtained from fresh lemon peel by expression. This is accomplished either by pressing and absorbing the oil with a sponge by hand, or by the use of machines. It is anticipated that the machine process of extraction will supersede the sponge method (see *Chem. & Drugg.*, i/1929, 134, 234, 308, and *ibid.*, ii/1929, 289). It is stated that the machine-made oil is inferior in flavour to hand-pressed oil.

Method of preparation described. As a result of the standardisation of the oil to a content of 4% of citral, a large proportion of the oil exported from Sicily is doctored down with lemon terpenes to meet the minimum standard.—*Chem. & Drugg.*, ii/1927, 161.

The oil should not be exposed to light or air, and the presence of lemon juice also causes deterioration.—*Finnemore*.

An oil with an optical rotation exceeding +76° indicates that the oil has suffered deterioration; the acid value of the fresh oil is very low, increasing on keeping. Oil which has deteriorated gives a brown colour on shaking with hydrochloric acid.—*Chem. & Drugg.*, i/1928, 780.

Hydroxylamine process of estimating aldehydes and ketones including citral.—A. H. Bennett and F. K. Donovan, *Analyst*, 1922, 146; see also Report of the Essential Oil Sub-Committee on Uniformity of Analytical Methods, *Analyst*, 1934, 105.

For the determination of the end-point with solution of hydroxylamine, daylight or a daylight lamp is essential.—C. T. Bennett, *Pharm. J.*, i/1933, 150.

Californian lemon oil, probably owing to the method of preparation, has a low residue on evaporation.

- Oleum Limonis Deterpenatum (B.P.C.). Contains 40 to 50% w/w of citral. Sp. gr., 0.890 to 0.905; α_D , -4° to -9°; n_{D20° 1.479 to 1.483. Soluble in 3 volumes of alcohol (80%).

Terpeneless oil of lemon is mainly produced in S. Italy and Sicily. The lemon oil used is the finest obtainable. The yield is about 5% with the following characteristics:—

Sp. gr., 0.897 to 0.904; n_{D20° , 1.477 to 1.483; α_D , -2.0° to -3.5°; citra content, 40 to 50%; solubility, 1 in 1 of 80% alcohol.

Citral obtained from lemon grass oil, if purified to such an extent that the verbena odour is removed, may be used as an adulterant as can be seen from the following figures:—

| | Sp. gr. | α_D | Citral % |
|-----------------------------|----------------|--------------|----------|
| Sesquiterpeneless lemon oil | 0.895 | 0 to -1 | 65 |
| Terpeneless lemon oil .. | 0.897 to 0.904 | -2.0 to -3.5 | 40 to 50 |
| Citral | 0.896 | 0 | 100 |

The ester content is a guide to the detection of citral adulteration, but flavour and aroma are the best guides in conjunction with the analytical data.—Dalton, *Perfum. essent. Oil Rec.*, 1928, 7.

The removal of the sesquiterpenes from the oil causes it to lose its sweetness and softness, and the best oil for flavour and aroma is one containing under 40% of citral.—E. J. Parry, *Chem. & Drugg.*, ii/1913, 378.

The fluorescence under ultra-violet light.—See note under *Oleum Aurantii*.

OLEUM MELALEUCÆ ALTERNIFOLIÆ

Tea Tree Oil. Commercial tea tree oil is obtained from *Melaleuca alternifolia*, *Melaleuca linariifolia* and *Leptospermum citratum*. The oil of *M. alternifolia*, which is also known as titrol, has the following characters: Sp. gr., 0.8950 to 0.9050; α_D , $+6.8^\circ$ to $+9.8^\circ$; $n_{D_{25}^\circ}$, 1.4760 to 1.4810; ester number, 2 to 7; ester number after acetylation, 80 to 90; cineole, not more than 10%. *M. linariifolia* yields a similar oil, but has a cineole content of from 20 to 45%. The oil of *L. citratum* differs entirely from the oils of *Melaleuca* and contains 85% of citral and citronellal.—A. R. Penfold, *Aust. J. Pharm.*, 1941, 450.

The oil of *Melaleuca alternifolia* should be distinguished from that of *Leptospermum citratum*, lemon scented ti-tree oil, which has the following characteristics: sp. gr., 0.8792 to 0.8856; α_D , $+3.5^\circ$ to 5.0° ; $n_{D_{20}^\circ}$, 1.4688 to 1.4757. Containing 75 to 85% of total aldehydes, principally citral (45 to 50%), citronellal about 35%.—*Bull. tech. Mus., Sydney*, also *Perfum. essent. Oil Rec.*, 1936, 159; *ibid.*, 1929, 155.

OLEUM NEROLI

Oleum Neroli (B.P.C.). Soluble in 2 volumes of alcohol (80%) becoming turbid with more alcohol. Sp. gr., 0.870 to 0.885; α_D , 0° to $+8^\circ$; $n_{D_{20}^\circ}$, 1.468 to 1.477. Saponification value, not more than 70. *Oleum Aurantii Florum*, *N.F. VII*, has a sp. gr. at 25° of 0.863 to 0.880; α_D at 25° , $+1^\circ 30'$ to $+9^\circ 8'$. Complies with the same solubility test.

Oleum Patchouli. An account of the cultivation and distillation of patchouli oil in the Seychelles.—Haines, *Perfum. essent. Oil Rec.*, 1935, 171.

OLEUM PINI AROMATICUM

Oleum Pini Aromaticum (B.P.C.). Soluble in 2 volumes of alcohol (70%). Sp. gr., 0.9325 to 0.9465; α_D , $+7^\circ$ to $+15^\circ$; $n_{D_{20}^\circ}$, 1.4790 to 1.4870. The chief constituents of the oil are tertiary alcohols, principally α -terpineol, of which up to 70% may be present, secondary alcohols, mainly borneol and fenchyl alcohol, and smaller amounts of methyl chavacol and phenolic ethers.

OLEUM PINI PUMILIONIS

Oleum Pini Pumilionis (B.P.C.). Contains not less than 4% w/w of esters, calculated as bornyl acetate, $C_{12}H_{20}O_2$. Sp. gr., 0.865 to 0.873; α_D , -6° to -15° ; n_{D20} , 1.470 to 1.480. The U.S.P. XII oil is required to contain not less than 4% of esters as bornyl acetate; soluble in 4.5 to 8 volumes of alcohol (90%); sp. gr. at 25° , 0.853 to 0.869; α_D at 25° , -5° to -15° . Less than 4% of the oil should distil below 165° .

The limits as set forth in the literature for the physico-chemical properties should be revised in accordance with the following determined on genuine samples:—sp. gr. at 25° , 0.853 to 0.871; optical rotation, -3° to -16° ; refractive index at 20° , 1.4750 to 1.4800; ester content (calculated as bornyl acetate) 3 to 10%; solubility at 25° , 1 in 4.5 to 10 parts of alcohol 90%, often with turbidity; boiling range, less than 10° , distills below 165° .—C. H. Grimm, E. E. Langenau and E. S. Guenther, *J. Amer. pharm. Ass., Sci. Edn.*, 1941, 209.

OLEUM ROSÆ

Oleum Rosæ (B.P.C.). Should congeal at 18° to 22° and melt at 19° to 23° , when tested by the method of the B.P. for Oleum Anisi. Sp. gr. ($30^\circ/15.5^\circ$), 0.852 to 0.862; α_D , -2° to -4° ; n_{D25} , 1.458 to 1.465. Oleum Rosæ, U.S.P. XII, produces a clear mixture with an equal volume of chloroform; on diluting with 20 volumes of alcohol (90%) the liquid is neutral or slightly acid to litmus, and on standing produces a crystalline deposit; sp. gr. ($30^\circ/15^\circ$), 0.848 to 0.863; α_D , -1° to -4° at 25° ; n_{D30} , 1.457 to 1.463.

Analytical Characters of Bulgarian Otto of Rose. Ethyl alcohol is stated to be a natural constituent of the oil; it should therefore not be washed before analysis. The stearoptenes content is very variable. The acid value varies from 1.4 to 3.8. A high refractive index and a high rhodinol content appear to be characteristic of good Bulgarian otto. Physical and analytical data given for a number of samples.—Garnier and Sabétay, *C. R. Acad. Sci., Paris*, 1933, 1748; see also *Perfum. essent. Oil Rec.*, 1934, 347. Any oil with less than 40% of rhodinol is suspect.

The presence of ethyl alcohol is doubtful and may be due to ethoxy, methoxy or other groups interfering with the Zeisel reaction. The ratio of citronellol to geraniol is a standard rather than the individual percentages of those constituents. Table of physical and analytical data with ratio $\frac{\text{citronellol}}{\text{geraniol}}$ is given.—Parry and Seager, *Perfum. essent. Oil Rec.*, 1934, 213. See also *Perfum. essent. Oil Rec.*, 1933, 149, and Garnier, *Perfum. essent. Oil Rec.*, 1933, 370; also *Perfum. essent. Oil Rec.*, 1936, 278.

Details of cultivation and analysis of small samples of oil of rose in Cyprus.—*Perfum. essent. Oil Rec.*, 1930, 257.

GERANIOL $C_{15}H_{26}O=154.144$ (three-quarters of the liquid portion), and citronellol $C_{15}H_{26}O=156.16$ (the remaining 25%). Linalol is isomeric with geraniol, sp. gr., 0.870, B.p., 197° . It is contained in coriander, thyme and other oils and is either + or - rotatory.

Geraniol is an important base in perfumery. It is not made synthetically, but occurs in a number of oils, especially palmarosa and Java citronella—in these it is free, in other oils it occurs as ester: acetate and tiglate.

"RHODINOL" is a blend of the two alcohols geraniol and citronellol, from pelargonium leaf oil. Some workers give the name as synonymous with geraniol—others as synonymous with citronellol.

75% or 76% at most is the highest amount of alcohol calculated as geraniol that should be allowed in a normal pure otto. Pure otto never has specific

gravity as high as 0.862. Frequently it is as low as 0.850. Any otto with a refractive index below 1.4600 is adulterated, and almost invariably with alcohol. Considering that about 50% of the adulterated samples contain alcohol, which is used to adjust the high sp. gr. and refractive index of the geraniol compounds added, the following test is valuable:—

If 5 ml. be well shaken with 10 ml. of warm water and the mixture allowed to separate, the refractive index of the washed oil at 25° should not differ from that of the original oil by more than 0.0015 (absence of alcohol).

The determination of the refractive index should be made on the separated otto when quite clear, filtered if necessary, but not dried with any drying agent, since the original oil, owing to the method of distillation, is saturated with water.—Parry.

Although the predominating constituent, geraniol is by no means the most important, as both citronellol and nerol, and esters of the respective alcohols and other bodies, contribute largely to the fragrance of the oil. Phenyl ethyl alcohol, which possesses a mild odour, appears to be contained in otto and in neroli oil, not only as such, but also in the form of esters of benzoic and phenyl acetic acids. Although this alcohol is contained in exceedingly small quantity in otto, it represents quantitatively the chief volatile constituent of rose petals. Being freely soluble in water, it remains behind for the most part in the aqueous portion of the distillate from which the otto has been removed.

The so-called stearoptene of otto is a mixture of homologous hydrocarbons.

OLEUM ROSMARINI

Oleum Rosmarini (*B.P. Add. II*). Contains not less than 2% *w/w* of esters as bornyl acetate, $C_{12}H_{20}O_2$, and not less than 9% *w/w* of free alcohols as borneol, $C_{10}H_{18}O$. Sp. gr., 0.900 to 0.919; α_D , -5° to $+10^\circ$; n_{D20° , 1.466 to 1.476. Soluble in 1 volume of alcohol (90%) and in 10 volumes of alcohol (80%). Oleum Rosmarini, *U.S.P. XII*, contains not less than 1.5% of esters as bornyl acetate, and not less than 10% of total borneol, free and as esters. Sp. gr. at 25°, 0.894 to 0.912; α_D at 25°, -5° to $+10^\circ$; n_{D20° , 1.4640 to 1.4760.

Spanish rosemary oil of really first quality can scarcely be distinguished from French oil, but the coarser quality is, as a rule, found on the market. For analytical characters see Maurice and Salamon, *Perfum. essent. Oil Rec.*, 1923, 231, also Simmons, *Perfum. essent. Oil Rec.*, 1923, 233.

The ester content of Spanish oil is usually below the *B.P.* limit.

For the characters of Sicilian essential oils, including rosemary, see Pellini, *Chem. & Drugg.*, ii/1923, 391, and for Yugoslavian oils see *Perfum. essent. Oil Rec.*, 1931, 62.

The presence of light camphor oil may be detected by the test for furfuraldehyde, *vide* test under *Ol. Menth. Pip.*

OLEUM SANTALI

Oleum Santali (*B.P. Add. I*). Contains not less than 2% *w/w* of esters, calculated as santalyl acetate, $C_{17}H_{26}O_2$, and not less than 90% *w/w* of free alcohols, calculated as santalol, $C_{15}H_{24}O$. Sp. gr., 0.973 to 0.985; α_D , -15° to -20° ; n_{D20° , 1.505 to 1.510. Soluble at 20° in 5 volumes of alcohol (70%). The *N.F. VII* oil has a sp. gr. at 25° of 0.965 to 0.980; α_D , -15° to -20° at 25°; n_{D20° , 1.500 to 1.510; yields not less than 90% of alcohols, as santalol.

Structure of the woods of sandalwood substitutes described.—*Perfum. essent. Oil Rec.*, 1931, 332. Kalamet, an Indian substitute.—*Perfum. essent. Oil Rec.*, 1932, 318.

Analytical characters of East Indian oil.—Clevenger, *Quart. J. Pharm.*, 1932, 590.

West Indian sandalwood oil is obtained from the wood of *Amyris balsamifera*. The oil is dextrorotatory. It contains amyrol, probably a mixture of alcohols which differ from santalol.

The yield of oil was found to vary considerably, being least in sandalwood chips, probably due to the inclusion of larger proportions of sap wood. The sp. gr. is sometimes outside the U.S.P. XI limits (0.965 to 0.980 at 25°), values both above and below being found. The optical rotation gave values up to -22.50. The refractive index of official and non-official varieties of sandalwood oil are essentially identical. The sp. gr. and refractive index are of little value for detecting non-official varieties, i.e., Australian, New Caledonian, African and *Amyris* species but the optical rotation is important.—J. F. Clavenger, *J. Amer. pharm. Ass.*, 1938, 580.

Oleum Santali Australiensis (B.P.). Contains not less than 90% w/w of free alcohols as $C_{15}H_{24}O$. Sp. gr., 0.970 to 0.976; α_D , -3° to -10°; n_{D20} , 1.498 to 1.508. Soluble in 3 to 6 volumes of alcohol (70%). Essence de Santal d'Australie and Essence de Santal Citrin, *Fr. Cx.* 1937, contain 80% of santalol, by acetylation in presence of pyridine.

Numerous papers have been published comparing East Indian and Australian sandalwood oils.

West Australian sandalwood oil of good quality is now available, containing 95% alcohol (calculated as santalol) and closely resembling the East Indian oil, although it has not been proved that the alcohols are identical with the santalols of the East Indian oil. The oil, which is obtained from *S. spicatum* and *S. lanceolatum*, is not inferior therapeutically to that obtained from *S. album*.—P. May, *Pharm. J.*, i/1928, 368.

No evidence that the alcohols in W. Australian oil differ from those of Mysore oil, and its therapeutic value is at least equal to that of *S. album*.—W. H. Simmons, *Chem. & Drugg.*, i/1928, 171. See also a *contra* view.—A. R. Penfold, *Chem. & Drugg.*, ii/1928, 496.

See also Venkatesaiya and Watson, *J. Soc. chem. Ind., Lond.*, Nov. 1928; Penfold, *Perfum. essent. Oil Rec.*, 1928, 417; and 1933, 46; also *ibid.*, 1932, 349, 376.

For the volatile oil of Queensland sandalwood (*Santalum lanceolatum*), see Jones and Smith, *Perfum. essent. Oil Rec.*, 1931, 47.

For the therapeutic action of sandalwood oils, both Australian and East Indian, see Boldecker and Ludwig, *Pharm. Ztg., Berlin*, 1928, 73, 938, per *Quart. J. Pharm.*, 1928, 666. Australian oil has no antiphlogistic properties and its substitution for the oil of *Santalum album* is not permissible.

Determination of Free Alcohols by means of acetic anhydride and sodium acetate includes free alcohols and combined, but gives deficient results for tertiary alcohols such as linalol. The usual method of acetylation gives results some 10% higher than those obtained in the presence of pyridine or by phthalic esterification; it is known to include also alcohols combined as esters, but when allowance is made for these the results are still from 5 to 8.5% higher. Method using pyridine in the process of acetylation, see Delaby, Sabetay and Breugnot, *Perfum. essent. Oil Rec.*, 1935, 334.

OLEUM SASSAFRAS

Oleum Sassafras (B.P.C.). Soluble in 3 volumes of alcohol (90%) the solution being neutral to litmus. Sp. gr., 1.070 to 1.084; n_{D20} , 1.523 to 1.531; α_D , +1° to +5°. Oleum Sassafras, U.S.P. XII, should be soluble in 2 volumes of alcohol

(90%). Sp. gr. at 25°, 1.065 to 1.077; α_D at 25°, +2° to +4°; n_{D20° , 1.5250 to 1.5350.

Safrolum (B.P.C.). $C_{10}H_{10}O_2=162.1$. The m.p., determined by the B.P. method for Oleum Anisi, is not below 11° and the congealing point not below 10°. Sp. gr., 1.104 to 1.107; n_{D20° , 1.536 to 1.539. Soluble in 3 volumes of alcohol (90%) and in 10 volumes of alcohol (80%).

OLEUM TEREBINTHINÆ

Oleum Terebinthinæ (B.P.). Sp. gr., 0.860 to 0.870; n_{D20° , 1.467 to 1.477. Iodine value, using a larger quantity of iodine monochloride and allowing absorption to proceed for exactly one hour, not less than 340. Residue, by rapid evaporation from a flat dish on a water-bath, not more than 0.5%. The B.P. Add. I directs that in determining the iodine value of Oleum Terebinthinæ the oil be weighed into a small glass tube and introduced into a dried vessel containing the iodine monochloride solution and carbon tetrachloride. Absorption is allowed to proceed in the dark for exactly 1 hour at a temperature of 15° to 20°. The U.S.P. XII oil has a sp. gr. at 25° of 0.854 to 0.868. n_{D20° , 1.4680 to 1.4780. 90% of the oil distils between 154° and 170°; complies with a test for acidity, and a test for mineral oil, when the unabsorbed viscous layer, on mixing with 4 volumes of sulphuric acid at 60° to 65°, does not exceed 1%; 2% w/v of residue on evaporation is allowed. The U.S.P. XII specifies that Oleum Terebinthinæ Rectificatum be used for internal use and it must not have become turbid; sp. gr. at 25°, 0.853 to 0.862; non-volatile residue, not more than 0.3%.

Terebinthina (N.F. VII). Contains not more than 2% of foreign organic matter; alcohol-insoluble residue, not more than 2%.

The B.P. specifies "oil distilled from the oleo-resin"; the oil so obtained is commercially known as "gum turpentine" to distinguish it from "wood turpentine" which is the first fraction obtained on the steam distillation of the stumps and waste. The two varieties closely resemble one another. For distinction between gum and wood turpentine see Parry, *The Chemistry of Essential Oils and Artificial Perfumes*.

The optical rotation of turpentine derived from different species of Pinus compared.—Herty, *Yearb. Pharm.*, 1908, 199.

Examination of turpentine and turpentine substitutes. Wood turpentine may be detected by shaking with an equal volume of saturated sulphurous acid solution. Wood turpentine assumes a yellow colour, Russian and Swedish turpentine become greenish-yellow, and American and French turpentine remain colourless.—J. H. Coste, *Analyst*, 1908, 219.

A rapid method for the determination of petroleum in turpentine is given by Frey, *Svensk farm. Tidsskr.*, 1908, per *Quart. J. Pharm.*, 1908, 201.

Assay. The following assay and standard for turpentine in Liniment of Turpentine is recommended by the Sub-Committee on the Assay of Galenicals of the Committee on Pharmaceutical Chemistry:—Weigh accurately about 50 g., acidify with dilute sulphuric acid, using solution of methyl orange as indicator, distil in steam and collect the distillate in a separator; from time to time separate the aqueous portion of the distillate and return it to the boiling-flask; when all the volatile matter has been distilled, remove the aqueous portion of

the distillate and measure the oily liquid. The oily liquid obtained should amount to not less than 63% *v/w* and not more than 70% *v/w* and should have refractive index at 20°, 1.465 to 1.477.—(*British Pharmacopœia Commission Report*, No. 11, May 1939.)

Turpentine and White Spirit for Paints.

The following *British Standard Specifications* have been prepared by the British Standards Institution for turpentine and white spirit for use in paints:—

B.S.S. No. 244—1936 relates to turpentine type I, and includes requirements regarding description (genuine refined gum spirits of turpentine), sp. gr. (0.862 to 0.872 at 15.5°), distillation (not more than 1% below 150° and not less than 95% below 170° at 760 mm. pressure), non-volatile residue (not exceeding 2% and is wholly organic), refractive index (1.469 to 1.478), unpolymerisable residue (not more than 11%), flash point (not below 90°F., Abel's closed test) and sampling.

B.S.S. No. 290—1936 refers to turpentine type II, which is genuine turpentine distilled from pine oleo-resins or obtained from resinous wood by steam or destructive distillation; the specifications give requirements for specific gravity (0.859 to 0.875), distillation (as for type I except 70% below 170° and not less than 90% below 180°), non-volatile residue (2%), refractive index (1.463 to 1.483), unpolymerisable matter (16%), flash point and sampling.

B.S.S. No. 245—1936 covers the requirements of white spirit for use in thinning paints and varnishes. It should be wholly a petroleum product complying with requirements for distillation (not more than 10% below 150° and not less than 80% below 190°), freedom from grease, non-volatile residues (on water-bath and by spontaneous evaporation), neutrality, freedom from objectionable sulphur compounds, volatility, and flash point (not below 78°).

The appendices to the three specifications give the methods to be used for determining the volatility, freedom from objectionable sulphur compounds, the polymerisation test and the procedure for the distillations.

Lævo-pinene or terebentene of Berthelot is obtained by fractionation of French oil of turpentine as a colourless mobile liquid of characteristic odour. Sp. gr., 0.8767 at 0° and 0.8619 at 17.9°.

Russian Turpentine Oil. Authentic samples contain 40 to 70% distilling between 155° and 160°, and consisting chiefly of pinene. The oils arriving in the London markets have these "middle runnings" removed.

Indian Turpentine, from *P. longifolia*, constituents of.—J. L. Simonsen, *J. chem. Soc.*, May 1929, 570.

OREGON AND COLORADO DOUGLAS FIR OILS from trees grown in Britain. Geraniol the chief odorous constituent of the first. The odour of the other appears due to the large proportion of pinene and bornyl acetate.—C. T. Bennett, *Perfum. essent. Oil Rec.*, 1920, 218.

Terebenum (B.P.). Sp. gr., 0.862 to 0.87; α_D , -2° to $+2^\circ$; n_{D20° , 1.471 to 1.474. Distils between 160° and 190° leaving only a slight viscous residue, and not less than 80% distils between 165° and 185°. Residue by rapid evaporation from a flat dish on a water-bath, not more than 2% *w/w*.

Terpini Hydras. (B.P.C.) melts between 116° and 119°. Ash, not more than 0.05%.

Terpineol (B.P. Add. VI). $C_{10}H_{18}O = 154.1$. Sp. gr., 0.934 to 0.938; n_{D20° , 1.4825 to 1.4855. Not less than 96% distils between 214° and 220°.

OLEA EXPRESSA

The term "expressed," as applied to oils, is only of generic value, as a great number of these oils are not prepared commercially

by an expression process. The methods used may be divided into three classes, a process of boiling out by water or steam, expression, and extraction by volatile solvents. The first two of these methods are very old, and in various parts of the world they are still practised in what is probably their original and very crude manner. Oils obtained by any of the above methods are often further treated by a refining and bleaching process to improve their quality. A **boiling out process** is mostly used for the preparation of animal oils and fats; the crude material being boiled with water or salt solution and the oil separated by gravity; oils obtained in this way are generally subjected to a refining process. **Expression** is used for a very large number of vegetable oils. The presses used in some parts of the world are still very crude, consisting of a lever and weights; in modern machinery advantage is taken of the hydraulic press, in which pressure round about three tons per square inch may be exerted. When the oil is expressed from the whole or ground material without any application of heat it is called "cold-drawn." Very often the ground material is subjected to moderate heating, with or without the addition of water, in the form of steam, and then pressed. In some cases these processes may be combined, a portion of the oil being obtained by cold expression and the material being then ground, heated and again pressed. Oils obtained by a process involving heating are generally darker in colour and of inferior taste and odour. **The solvent extraction process** is used for many different oils and also to remove the oil left in the "cake" by the hydraulic presses. Various solvents are used, petroleum ether, carbon tetrachloride, carbon disulphide and some of the chloro derivatives of ethane and ethylene. The product is generally inferior to an expressed oil, may contain traces of solvent or non-volatile residues, and generally requires refining and bleaching. **Refining and bleaching processes** are applied to oils to remove excessive fatty acids, colouring matter, mucilaginous and albuminous matter and the products of rancidity. The general process is first to neutralise the oil with soda, the free fatty acid being thus removed as soap. The oil is then, if necessary, bleached by charcoal or absorbent earths, and finally treated by steam *in vacuo* to remove traces of volatile substances. Details of the method of extraction used for industrial oils, with the chemical components and analytical data, can be found in *Chemical Technology and Analysis of Oils, Fats and Waxes*, Lewkowitsch; *Laboratory Companion to Fats and Oils Industry*, Lewkowitsch; *Edible Oils and Fats*, Fryer and Weston; *Technical Handbook of Oils, Fats and Waxes*, Elsdon; and other standard works.

British Standard Specifications have been prepared by the Technical Committee of the British Standards Institution for a number of animal and vegetable oils. Certain of these oils have monographs in the *B.P.* and *B.P.C.*, in which cases the British Standard Specifications differ in certain particulars and are not intended to be applied to medicinal oils. The following have been published:—

| | B.S.S. | Date |
|---|--------|------|
| Castor oil, first quality | 650 | 1936 |
| Coconut Oil | 628 | 1935 |
| Cod-liver Oil for sulphonation purposes | 868 | 1939 |
| Controlled Cod-liver Oil mixtures for animal feeding purposes | 910 | 1940 |
| Cotton Seed Oil, refined | 655 | 1936 |
| Ground Nut Oil | 629 | 1935 |
| Japanese and/or Korean Sardine Oil | 783 | 1938 |
| Linseed Oil, raw, for general purposes | 632 | 1935 |
| Linseed Oil, for paints | 242 | 1936 |
| Maize Oil, crude | 651 | 1936 |
| Oils, Thinners, Driers and Extenders for paints | 925 | 1940 |
| Olive Oil | 630 | 1935 |
| Palm Kernel Oil, crude | 652 | 1936 |
| Perilla Oil | 654 | 1936 |
| Rape Seed Oil | 631 | 1935 |
| Sesame Oil | 656 | 1936 |
| Soya Bean Oil | 653 | 1936 |
| Tung Oil, Type F for paints | 391 | 1936 |
| Veterinary Cod-liver Oil | 839 | 1939 |
| Vitamins A and D in Oil for animal feeding purposes | 909 | 1940 |
| Whale Oil | 836 | 1939 |
| Sampling of fats and fatty oils in packages or in bulk | 627 | 1935 |

Determination of Iodine Values of Oils and Fats. The iodine value of a substance is the weight of iodine absorbed by 100 parts by weight of the substance when determined by one of the following methods (*B.P. Add. II*):—

(1) **Iodine Monochloride Method.** The iodine monochloride solution is prepared by one of the following methods: (a) Dissolve 13 g. of iodine in 1000 ml. of glacial acetic acid. To 20 ml. of this solution add 15 ml. of solution of potassium iodide and 100 ml. of water and titrate the solution with N/10 sodium thiosulphate. Pass chlorine, washed and dried, through the remainder of the iodine solution until the amount of N/10 sodium thiosulphate required for titration is approximately, but not more than, doubled. (b) Iodine trichloride, 8 g.; iodine 9 g.; glacial acetic acid, sufficient to produce 1000 ml. Dissolve the iodine trichloride in about 200 ml. of glacial acetic acid; dissolve the iodine in about 500 ml. of glacial acetic acid; mix the two solutions, and add sufficient glacial acetic acid to produce the required volume.

Place the oil, or fat, accurately weighed, in a dry stoppered vessel, add 10 ml. of carbon tetrachloride, and dissolve. Add 20 ml. of solution of iodine monochloride, insert the stopper, previously moistened with solution of potassium iodide, and keep in a dark place at a temperature of about 17° for half an hour. Add 15 ml. of solution of potassium iodide and 100 ml. of water; shake, and titrate with N/10 sodium thiosulphate, using mucilage of starch as indicator. Note the number of millilitres required (a). At the same time carry out the operation in exactly the same manner but without the substance being tested, and note the number of millilitres of N/10 sodium thiosulphate required (b).

Calculate the iodine value from the following formula:—

$$\text{Iodine value} = \frac{(b - a) \times 0.01269 \times 100}{\text{Weight (in grammes) of substance.}}$$

The approximate weight, in grammes, of substance to be taken may be calculated by dividing 20 by the highest expected iodine value. If more than half the available halogen is absorbed, the test must be repeated on a smaller quantity of the substance being tested.

(2) **Pyridine Bromide Method.** The pyridine bromide solution is prepared as follows: Dissolve 8 g. of pyridine and 10 g. of sulphuric acid in 20 ml. of pure glacial acetic acid, keeping the mixture cool. Add 8 g. of bromine dissolved in 20 ml. of pure glacial acetic acid and dilute to 1000 ml. with pure glacial acetic acid.

Place the substance, accurately weighed, in a dry, stoppered vessel, add 10 ml. of carbon tetrachloride and dissolve. Add 25 ml. of solution of pyridine bromide and allow to stand for 10 minutes in a dark place. Complete the determination as described under the iodine monochloride method, beginning with the words "Add 15 ml. . . .". The approximate weight in grammes of substance to be

taken may be calculated by dividing 12.5 by the highest expected iodine value. If more than half the available halogen is absorbed the test must be repeated on a smaller quantity of the substance being tested.

For description of the original method of Von Hübl, see p. 190, Vol. II, 21st Edn.

Dichloramine has been used for the determination of iodine values and the results, within the limits of experimental error, agree with those obtained with Wijs' solution. The reagent is prepared as follows:—To a solution of 0.05 mol. of dichloramine in about 700 ml. of halogen stable acetic acid add 0.1 mol. of dry powdered potassium iodide in small quantities at a time with continual shaking. When all the iodide is dissolved, dilute to 1000 ml. with acetic acid.

The reagent may be stored in a bottle with a dark felt cover to minimise decomposition by light and to deter freezing. The iodine equivalent is determined in the usual way by determining the iodine liberated from a known volume of excess of aqueous potassium iodide.

Comparison of results of the Hübl, Wijs, Hanus and Margosches methods by determining with them the iodine values of oleic, linolic and erucic acids, triolein and trilinolin. The methods of Hübl and Hanus show no significant differences for oleic acid and trilinolin, and methods of Wijs and Hanus show no significant differences with linolic acid, erucic acid and triolein.—I. Netto, per *Analyst*, 1936, 867.

THIOCYANOGEN VALUE—a new constant of oils and fats—is of special use in determining the amount of linolic acid in an oil. Thiocyanogen, like iodine, is quantitatively absorbed by substances containing a double bond, but with fatty acids containing a triple bond (stearolic, behenolic) there is no absorption; and with linolic acid there is only absorption of half the thiocyanogen corresponding to its iodine value.—*Analyst*, 1926, 157, 264.

Determination of Unsaponifiable Matter. Unsaponifiable matter is defined as consisting of that material present in oils and fats which, after saponification of the oil or fat by caustic alkali and extraction by a solvent specified remains non-volatile on drying at 80°.

The following is the method given in *B.P. Add. II* for the determination of unsaponifiable matter in fixed oils and fats.

Weigh accurately a quantity of oil or fat, not exceeding 2.5 g., but not less than 2.0 g., and boil on a water-bath for one hour with 25 ml. of N/2 alcoholic potassium hydroxide in a flask provided with a reflux condenser. Wash the contents of the flask into a separator by means of 50 ml. of water and extract by shaking vigorously, while still slightly warm, with three successive quantities of 50 ml. of ether, washing the flask with the first quantity of ether. Mix the ethereal solutions in a separator containing 20 ml. of water. (If the ethereal solutions contain solid suspended matter, filter them into the separator through a fat-free filter-paper and wash the filter-paper with ether.) Gently rotate the separator for a few minutes without violent shaking, allow the liquids to separate, and run off the aqueous layer. Wash the ethereal solution by shaking vigorously with two successive quantities of 20 ml. of water; then wash three times with 20 ml. of N/2 aqueous potassium hydroxide by shaking vigorously on each occasion, each alkali treatment being followed by washing with 20 ml. of water. Finally, wash with successive quantities of 20 ml. of water until the aqueous layer is no longer alkaline to solution of phenolphthalein. Transfer the ethereal extract to a weighed flask, washing out the separator with ether; distil off the ether and add 3 ml. of acetone. By the aid of a gentle current of air remove the solvent completely from the flask, which is preferably held obliquely and rotated, almost entirely immersed in a boiling water-bath. Dry to constant weight at a temperature not exceeding 80°. After attaining constant weight, dissolve the contents of the flask in 10 ml. of freshly-boiled alcohol (95%), previously neutralised to solution of phenolphthalein. Titrate with N/10 sodium hydroxide, using solution of phenolphthalein as indicator. If the amount of N/10 sodium hydroxide required does not exceed 0.1 ml., the unsaponifiable matter is to be taken as the amount weighed. Calculate the unsaponifiable matter as a percentage of the oil or fat. If the amount of N/10 sodium hydroxide required exceeds 0.1 ml. the test has not been properly carried out and must be repeated. *Reagent.*—Solution of potassium hydroxide, alcoholic, N/2; a solution containing 28.05 g. KOH in 1000 ml. of alcohol (95%).

Determination of Acetyl Value. The *B.P. Add. VI* defines the acetyl value of a substance as the number of mg. of potassium hydroxide required to

neutralise the acetic acid liberated when 1 g. of the acetylated substance is hydrolysed. The acetyl value may be calculated from the following formula:

$$\text{Acetyl Value} = \frac{(b - a) 1336}{1336 - a}$$

where a = saponification value of the original substance

and b = saponification value of the substance acetylated by the method described in the *B.P.* for the determination of free alcohols in volatile oils.

Ultra-violet Absorption of certain vegetable oils may be used as an indication of their commercial treatment. The mean value of e at 270.0 m μ ($e = \log. I_0/I$) for 1% solutions in hexane in a cell 1 cm. thick, for virgin olive oil = 0.160, for refined oil = 0.700 and for oil from refined pulps = 1.450. The effect of heating an oil is to raise e .—J. Guillot, *Ann. Falsif.*, 1935, 28, 69, per *Analyst*, 1935, 432.

Colour Measurement of Oils. The inaccuracies of the Lovibond method of measurement due to the variations of the human sight are eliminated by the use of Wratten filters to obtain a light in a narrow wave-band, a copper sulphate cell to eliminate the infra-red and a photo-electric cell to measure the light transmitted through a cell containing the oil. A series of Wratten filters may be used or the readings confined to two, Wratten No. 62 and No. 71A. The percentage of light transmitted is obtained by dividing the reading obtained with the oil by that obtained with an empty cell and multiplying by 100. This figure subtracted from 100 gives the percentage of light extinguished. Readings are reproducible to within 1 or 2% by different workers. The results obtained with a Wratten No. 71A are roughly correlated to those obtained in Lovibond red units but are in different units.—E. R. Bolton and K. A. Williams, *Analyst*, 1935, 447.

Products Responsible for the Taste and Odour of Vegetable Oils. The process of refining removes something which cannot be detected chemically, but which is sufficient to alter the taste of the oil. This occurs during the deodorisation with superheated steam. The substances removed during this process are hydrocarbons. In olive and arachis oils the amount of these substances is estimated at 0.07 and 0.0018 g. per kg. respectively.—Mercelet, *J. Pharm. Chim.*, ii/1936, 213.

Estimation of Rancidity. The Kreis test is usually employed. Kerr's modification of this test is as follows: 10 ml. of melted fat or oil is vigorously shaken for thirty seconds with 10 ml. of hydrochloric acid (sp. gr. 1.19), 10 ml. of a 0.1% solution of phloroglucinol in ether is added, and the mixture shaken. A red colour in the acid layer indicates that the fat or oil is rancid.—*Industr. Engng Chem., anal. Edn.*, 1918, 471.

The substance present in rancid oils and fats which gives rise to the red colour in the Kreis test is epihydrinaldehyde. The Kreis test is usually applied as a qualitative test, the quantitative result by measurement of the depth of the red colour being difficult and often inaccurate. The following method which is standardised on epihydrinaldehyde gives quantitative results. The oil (0.5 to 1 g.) is dissolved in sufficient of a 1% solution of phloroglucinol in acetone to give a 10% solution. A number of drops of sulphuric acid equal to the number of ml. of solution are added, and the mixture is placed in a water-bath at 10° for 15 minutes. The depth of the red colour is measured in a Lovibond tintometer. Red units $-0.625 \div 97$ = rancidity as percentage of epihydrinaldehyde. Water must be excluded from the test.—M. Pyke, *Analyst*, 1935, 515.

Fats may undergo degradation in other ways than by the formation of epihydrinaldehyde, the proportion of which increases to a certain point, but finally it may become constant or even diminish as auto-oxidation proceeds. Strict parallelism between the intensity of the Kreis reaction and the extent to which auto-oxidation has proceeded cannot therefore be expected. The red colour is produced by a number of substances such as allyl alcohol, allylamine and diallylcarbamide; also with advanced deterioration of fats sparingly soluble, colourless aldehyde phloroglucosides are formed, the Kreis colour reaction being prevented. The following method avoids the interference of any of these causes. The oil is mixed in a short test-tube with an equal quantity of ice-cooled concentrated hydrochloric acid. A cotton-wool plug, inserted in the upper dry part of the tube, is moistened with 1 ml. of a 0.1% solution of phloroglucinol in alcohol and 10 drops of at least 20% hydrochloric acid. The tube is well shaken for 1 to 2 minutes without splashing the cotton and may if necessary be

gently warmed (to about 40°). Red colour of the lower surface of the cotton indicates epihydrinaldehyde. A quantitative method using a special apparatus is also described.—K. Taüfel and Sadler, *Analyst*, 1934, 353.

Oils protected from light may remain free from rancidity for several months, but will give strong positive tests with Kreis reagent.—N. R. Col and J. A. Le Clerc, *Industr. Engng Chem., anal. Edn.*, 1934, 245.

A method based on the determination of the amount of iodine liberated from potassium or barium iodide, stated to be applicable to rancid fats of all types, even such as do not invariably give indication of rancidity with the Kreis test such as rancid cacao butter and oils blown at high temperatures, is described by A. Taffel and C. Revis, *J. Soc. chem. Ind., Lond.*, 1931, 87T.

Selective Oxidation of Animal and Vegetable Fats. Selective oxidation is used as a means to determine the purity of an animal or vegetable fat. Conditions are established under which the amount of oxidation of the more highly unsaturated acids is far greater than that of the less unsaturated and the difference between them is constant and measurable. A weighed quantity of oil or fat is treated with a solution of sodium dichromate in acetic acid for a definite time and at a definite temperature. Ferrous sulphate is then added and the excess estimated with standard potassium permanganate solution, diphenylamine oxidation-reduction indicator being used. From this an oxidation value is calculated. Fats with similar iodine value do not give similar oxidation values. The method is particularly applicable for the detection of hydrogenated fats which give low oxidation values, making their detection in other fats fairly certain.—W. A. Alexander, *Analyst*, 1938, 157.

The Bellier Values. Bellier values for different oils are as follows: arachis 38-41; coconut 10-5; cod-liver 9-5; mastic tree oil 16-75-17-75; linseed 16-5-20; olive 9-5-19; castor 0-5; soya bean 16-19; tea-seed 7-10; olive oils of different origins; Morocco 10-5; Tunis 16; Tunis with 10% arachis 19; Sfax 17; Sfax with 10% arachis oil 20-5.—R. Marcille, *Analyst*, 1940, 170.

The Blarez Value. The temperature of crystallisation of the alcoholic solution of the potassium soaps of the fatty acids obtained by saponifying 1-5 ml. oil with 15 ml. alcoholic potash (45 g. per litre). Pure olive oil 10-16, average 12; with 10% arachis oil the figure becomes 16-5; pure arachis oil 28.—R. Marcille, *Analyst*, 1940, 170.

Antioxygens Present in Oils. The naturally occurring antioxygens present in oils are destroyed when the oils are boiled with dilute mineral acids or with water. The antioxygens are present to a greater degree in the residual material of the seeds from which the oil is extracted than in the extracted oil. Concentrates have been prepared from soya-bean cake and from linseed oil and have been called inhibitor concentrates; they are probably a complex mixture of organic compounds. Considerable research has been done, see Olcott and Mattill, *J. Amer. chem. Soc.*, 1936, 1627; T. G. Green and T. P. Hilditch, *J. Soc. chem. Ind., Lond.*, 1937, 23T.

Oat starch has been shown to be of use as an antioxygen to retard the formation of rancidity in lard and oleomargarine, from 0-5 to 1-0% being added.—F. N. Peters and S. Musher, *Industr. Engng Chem., anal. Edn.*, 1937, 146.

NOTES ON INDIVIDUAL FIXED OILS

For other oils see under the corresponding drugs.

OLEUM ARACHIS

Oleum Arachis (B.P.). Sp. gr., 0-916 to 0-920. $n_{D40^{\circ}}$, 1-4625 to 1-4645; acid value, not more than 4; saponification value, 188 to 196; iodine value, 85 to 99. Complies with tests for absence of cottonseed oil, sesame oil and other vegetable oils. Huile d'Arachide, *Fr. Cx.* 1937, commences to solidify at 3°; at -5° it forms a semi-transparent fat; $n_{D25^{\circ}}$, 1-4704 to 1-4714.

The B.S.S. No. 629-1935 requires the oil to remain clear when kept at a temperature of 17-5° to 20° for 24 hours. It also includes requirements for

colour, sp. gr. (0.917 to 0.919), n_{D20}° (1.470 to 1.472), saponification value (not below 188), iodine value (85 to 99), acidity and unsaponifiable matter. The apparent proportion of arachis oil is calculated from the weight of crystals obtained in the "Evers" test after applying corrections given for solubility of arachidic acid in alcohol and a factor for converting the acid to arachis oil; it should contain not less than 96%.

To test for arachis oil in other oils, boil 1 ml. for 5 minutes under a reflux condenser with 5 ml. of 1.5 N alcoholic potash, add 1.5 ml. of acetic acid and 50 ml. of 70% alcohol, warm until clear, cool slowly to 15.5°; at this temperature it should remain clear for 5 minutes. If a precipitate is formed, 5 g. of the oil are refluxed for 5 minutes with 25 ml. of 1.5 N alcoholic potash and then 7.5 ml. of acetic acid and 100 ml. of 70% alcohol, containing 1% hydrochloric acid, added. Keep at 12° to 14° for one hour and filter, washing with the alcohol hydrochloric acid mixture, at 17° to 19°. Dissolve the precipitate in hot 90% alcohol and cool to 15° for 1 to 3 hours. Wash any crystals and dissolve in ether, evaporate and dry at 100°. The m.p., and the m.p. after recrystallisation, should be below 71°. If no crystals are formed dilute the alcohol to 70% and keep at 17° to 19° for one hour.

Arachis Oil in Other Oils. The following test for absence of arachis oil in other oils is recommended by the Sub-Committee on Fixed Oils, etc., of the Committee on Pharmaceutical Chemistry:—Boil 1 ml. of the oil in a small flask under a reflux condenser with 5 ml. of 1.5 N alcoholic potassium hydroxide for ten minutes; add 50 ml. of alcohol (70%) and 0.8 ml. of hydrochloric acid. Cool, with a thermometer in the liquid, with continuous stirring, so that the temperature falls by about 1° per minute. Note the temperature at which a turbidity appears. No turbidity appears above the following temperatures for the respective oils:—Almond oil 4°, olive oil 9°. If a turbidity is formed above the required temperature, carry out the following test:—Boil 5 g. of the oil in a 200-ml. conical flask with 25 ml. of 1.5 N alcoholic potassium hydroxide for five minutes under a reflux condenser. To the hot solution add 7.5 ml. of acetic acid and 100 ml. of alcohol (70%), containing 1 ml. of hydrochloric acid. Maintain the temperature for an hour at 12° to 14°. Filter, and wash with the same mixture of alcohol (70%) and hydrochloric acid at 17° to 19°, the precipitate being broken up occasionally by means of a platinum wire bent into a loop. The washing is continued, until the washings give no turbidity with water. Dissolve the precipitate according to its bulk in 25 to 70 ml. of hot alcohol (90%), cool, and allow it to stand at 15° for three hours. If no crystals appear arachis oil is absent. If any crystals appear, filter, and wash at 15° with about half the volume of alcohol (90%), used for crystallisation, and, finally, with 50 ml. of alcohol (70%). Dissolve the crystals in warm ether, and dry at 100°. The melting-point is lower than 71°. Re-crystallise from a small quantity of alcohol (90%); the melting-point, after drying at 100°, remains lower than 71° —(British Pharmacopœia Commission Report, No. 11, May 1939.)

OLEUM COCOIS

Oleum Cocois (B.P.C.). Solidifying-point, 22° to 23.5°; n_{D40}° , 1.4485 to 1.4495; acid value, not more than 6; saponification value, 255 to 258; iodine value, 7.9 to 9.5.

Coconut oil from copra from four sources (Inner South Sea Islands, Borneo, Celebes and Rabaul) were found not to differ significantly in their properties. The mixed fatty acids prepared by the Twitchell process, fractionated, and then the methylated fractions refractionated, were found to be composed of the saturated acids, caproic 0.3%; caprylic 9.17%; capric 9.67%; lauric, 44.05%; myristic 15.86%; palmitic 9.58%; stearic 3.16%; with a small proportion of arachidic acid and the unsaturated acids oleic 6.28% and linolic 1.53% —H. Nobori and M. Kawabata, *Analyst*, 1941 299.

A British Standard Specification (B.S.S. No. 628—1935) has been issued by the British Standards Institution for coconut oil and includes requirements regarding moisture content, colour, refractive index (1.4485 to 1.4492), iodine value (7.0 to 9.5), saponification value (not below 255), acidity (not more than the equivalent of 5.0% of lauric acid) and unsaponifiable matter (not exceeding 0.8%). The methods used for the tests and methods recommended for sampling fats and fatty oils are included in this and similar specifications.

Palm Kernel Oil. A British Standard Specification, B.S.S. No. 652—1936, has been issued for crude palm kernel oil and includes requirements regarding colour, refractive index (1.443 to 1.451 at 40°), iodine value (14 to 19), saponification value (242 to 252) and acidity (not more than the equivalent of 6% of lauric acid).

OLEUM GOSSYPII SEMINIS

Oleum Gossypii Seminis (B.P.). Sp. gr., 0.920 to 0.925; n_{D40} , 1.4645 to 1.4655; acid value, not more than 0.5; saponification value, 190 to 198; iodine value, 103 to 115. Particles of fat separate below 12° and it congeals between 0° and -5°. Complies with tests for absence of alkali, sesame oil and arachis oil.

Cottonseed oil may be detected in other oils by mixing in a tube 2.5 ml. of the oil with 1.25 ml. of amyl alcohol and 1.25 ml. of 1% precipitated sulphur in carbon disulphide and placing in a boiling water-bath; no reddish colour should develop within 30 minutes (Halphen's test). **Oleum Gossypii Seminis, U.S.P. XII**, has at 25° a sp. gr. of 0.915 to 0.921; saponification value, 190 to 198; iodine value, 105 to 114; solidification point of the fatty acids, 28° to 35°.

The B.S.S. No. 655—1936 for refined cottonseed oil does not apply to medicinal oil included in the B.P. The specification requires the oil to be the product of alkali refining the oil obtained by expression or extraction; it includes requirements regarding colour for deodorised oil and for common edible oil, sp. gr., refractive index, iodine value, saponification value (not below 192), acidity (not more than the equivalent of 0.2% of oleic acid) and unsaponifiable matter.

Oleum Lini (B.P.). Sp. gr. 0.930 to 0.940; n_{D40} , 1.4725 to 1.4750; acid value, not more than 5.0; saponification value, 187 to 195; unsaponifiable matter, not more than 1.5%; iodine value, 170 to 200. The **U.S.P. XII** oil has a sp. gr. of 0.925 to 0.935 at 25°; iodine value, not less than 170.

Raw Linseed Oil for General Purposes. The British Standards Specification for oil for general purposes, B.S.S. No. 632—1935, includes requirements for colour, sp. gr. (0.931 to 0.936), refractive index at 20° (1.4800 to 1.4835), iodine value (not below 175), saponification value (not below 188), acidity (not more than the equivalent of 2.0% of oleic acid), drying time, and unsaponifiable matter.

Linseed Oils for Paints.

The following British Standard Specifications have been prepared for linseed oil for paints:—

B.S.S. No. 242—1936 covers refined oil; the specification includes requirements regarding description, colour (not darker than fresh 0.02% iodine in 0.2% potassium iodide solution), sp. gr. (0.930 to 0.934 at 15.5°), refractive index (1.4808 to 1.4824), iodine value, saponification value, acidity, drying time, unsaponifiable matter and sampling.

B.S.S. No. 243—1936 relates to raw oil and includes requirements regarding description, colour, sp. gr. (0.931 to 0.936), n_D (1.4800 to 1.4835), iodine value, saponification value, acidity, drying time, unsaponifiable matter and sampling.

B.S.S. No. 259—1936 refers to boiled linseed oil, the specification including requirements for description, colour, sp. gr. (0.935 to 0.955 at 15° and within ± 0.002 of that of an agreed sample), acidity (not exceeding the equivalent of 4.0% of oleic acid), drying time (not more than 24 hours at 60° to 70°F.), ash (not more than 0.5%), unsaponifiable matter (not more than 2.5%), rosinate driers and sampling.

The appendices to the three specifications describe the methods to be used for the determinations of iodine value (Wijs), saponification value, acidity, drying time and unsaponifiable matter (this method is the process adopted by the Council of the Society of Public Analysts).—*Analyst*, 1933, 203.

OLEUM HIPPOGLOSSI

Oleum Hippoglossi (*B.P. Add. II*). Determined by the assay for vitamin A in relation to the Standard Preparation, contains in 1 g. not less than 30,000 units of vitamin A. The vitamin D activity varies and is usually between 2500 and 3500 units per g.; when a statement is made of the number of units of vitamin D in halibut-liver oil the units enumerated should be those described under the biological assay of vitamin D. Sp. gr., 0.924 to 0.929; acid value not greater than 1.0; saponification value not greater than 175; iodine value, not less than 115; iodine value of glycerides, 115 to 130; unsaponifiable matter, not less than 8%. Ultra-violet absorption at 300 m μ not more than 75% of that at 328 m μ . *B.P. Add. IV* alters the acid value to not more than 6.0, the iodine value to not less than 112, the iodine value of glycerides to 112 to 130, and the unsaponifiable matter to not less than 7%. Oleum Hippoglossi, *U.S.P. XII*, contains not less than 60,000 *U.S.P.* units of vitamin A and not less than 6000 *U.S.P.* units of vitamin D per g., and may be flavoured by the addition of not more than 1% of an official flavouring substance. Sp. gr. at 25°, 0.920 to 0.930; unsaponifiable matter, 7 to 13.5%; saponification value, 160 to 180; iodine value 125 to 155. 2 g. contains free fatty acids equivalent to not more than 1 ml. of N/10 sodium hydroxide.

Determination of the Iodine Value of the Glycerides of Halibut-liver Oil (*B.P. Add. II*). Determine the iodine value of the oil by the pyridine bromide method (x). Determine the unsaponifiable matter (S) using 1 g. of the oil, evaporating the acetone from the unsaponifiable matter by means of a current of nitrogen and drying the residue at 80° in a current of nitrogen. Weigh the residue and immediately determine the iodine value by the pyridine bromide method (y). Calculate the iodine value of the glycerides from the formula:

$$\frac{100x - Sy}{100 - S}$$

Determination of Ultra-violet Absorption. The *B.P. Add. II* directs that the ultra-violet absorption of halibut-liver oil is determined at 328 m μ and at 300 m μ on a solution of the oil in cyclohexane.

Blue values and iodine values of samples of halibut-liver oils of known origin compared with those of samples of the commercial oil and mixtures with cod-liver oil.—R. T. M. Haines and J. C. Drummond, *J. Soc. chem. Ind., Lond.*, 1934, 81T.

The "blue values" of samples of halibut-liver oil examined varied from 300 to 1720.—R. T. M. Haines and J. C. Drummond, *Brit. med. J.*, i/1933, 558.

Vitamin A Content of Fish-liver Oils (other than Cod). The range of vitamin A concentration is at least 2500 : 1 and is not parallel with vitamin D potency. The liver oils of haddock, whiting, skate of medium or small size, codling, and immature or small fish generally, are poor in vitamin A. Oils from

pollack, saithe, hake and ling are similar in potency to cod-liver oil; salmon, turbot, sturgeon and especially halibut yield liver oils rich in vitamin A. The larger halibut occurring in northern waters yield the better liver oil. Unlike the oils of other fish, halibut-liver oil shows a seasonal variation in vitamin A content independent of the spawning period. The oil is richest in vitamin A in May, subsequently falling, and rising to a second smaller maximum in September. There is possibly a connection between vitamin A content and the abundance of planktonic organisms from which the fish probably obtain carotene for conversion to the vitamin.—J. A. Lovern, J. R. Edisbury and R. A. Morton, *Biochem. J.*, 1933, 1461.

Oils obtained from the stomach, mesentery and intestine contain up to ten times as much vitamin A as does halibut-liver oil, and as large a quantity may be obtained from the viscera as from the liver although the latter is of considerably greater weight.—J. A. Lovern, *Nature, Lond.*, ii/1937, 276.

Analytical Data

It is the practice to standardise oils for sale to a definite vitamin A content. This may be done either by mixing strong and weak halibut-liver oils to give the desired vitamin content or by diluting a strong halibut-liver oil with another fish-liver oil, such as cod-liver oil, or even with a vegetable oil. There seems no objection to this practice, but if any other oil is added the product cannot be described as natural halibut-liver oil. The following variations were found in 33 samples of halibut-liver oils obtained during two seasons: Blue value, 205 to 7100; vitamin A $E_{1\text{cm}}^{1\%}$, 328 m μ , 6.8 to 144; sp. gr., 0.922 to 0.9286; n_{D40° , 1.470 to 1.488; iodine value, 111 to 171; saponification value, 150 to 175; unsaponifiable matter, 8.3 to 21.5%.—N. Evers and W. Smith, *Pharm. J.*, i/1935, 417.

Results are recorded of analyses of 30 samples of halibut-liver oil. The following ranges were found:—Blue value, 569 to 12,930; iodine value, 114 to 161; n_{D40° , 1.4688 to 1.4887; unsaponifiable matter, 6.34 to 17.4; sterols in unsaponifiable matter, 31.1 to 73.8. There is an inverse relationship between the amounts of sterol and of vitamin A.—R. T. M. Haines and J. C. Drummond, *Analyst*, 1936, 2.

The following ranges were obtained in analyses of 46 samples of halibut-liver oil during the 1935 season; average values obtained are included in brackets—Vitamin A, Blue value 495 to 6300 (1810); units per g. ($E_{1\text{cm}}^{1\%} \times 1600$) 18,700 to 211,300 (58,620). Vitamin D (determined on 3 bulked samples of the 46 batches), 2300 to 2800 (2560) units per g. Sp. gr. 0.924 to 0.929 (0.9265); n_{D40° , 1.4709 to 1.4836 (1.4739). Saponification value, 160 to 176 (171.2). Iodine value, 115 to 131 (121.4). Unsaponifiable matter % 7.2 to 17.55 (10.42). Figures are also given for the acid values and for the iodine values of the unsaponifiable matter, the glycerides and the non-vitamin A unsaponifiable matter.—N. Evers, A. G. Jones and W. Smith, *Analyst*, 1936, 7.

OLEUM HYDNOCARPI

Oleum Hydnocharpi (B.P.). Sp. gr. (25°/25°), 0.950 to 0.960; m.p., 20° to 25°; specific rotation of a 10% w/v solution in chloroform, not less than +53°; n_{D40° , 1.472 to 1.476. Acid value, not more than 25; saponification value, 198 to 204; iodine value 97 to 103.

Oleum Hydnocharpi Æthylicum (B.P.). Sp. gr., 0.905 to 0.910; α_D , not less than +45°; n_{D20° , 1.458 to 1.462; acid value, not more than 1.0; saponification value, 190 to 196; iodine value, 88 to 94. Æthyliis Chaulmoogras, *U.S.P. XII*, has a sp. gr. of about 0.904 at 25°; specific rotation, on a 50% v/v solution in chloroform, not less than +44.5°; saponification value, 190 to 196; iodine value, 90 to 100.

Oleum Chaulmoogræ (B.P.C.). M.p. about 25°. Sp. gr., about 0.95 at 25°; specific rotation at 20° on a 10% w/v solution

in chloroform, +48° to +52°; acid value, 22 to 30; saponification value, 196 to 213; iodine value, 98 to 104. M.p. of the mixed fatty acids, 44° to 45°. Oleum Chaulmoogræ, *U.S.P. XII*, complies with a limit for free fatty acids, a test for free fatty acids or castor oil, has a saponification value of 196 to 213, and an iodine value of 93 to 104.

Chemical Composition of the oil from the seeds of *Hydnocarpus Kurzii*. By distillation of the ethyl esters *in vacuo* at below 0.05 mm., by which means the last 10 to 15% of the esters were obtained without appreciable decomposition, the following substances were isolated: taraktogenic acid, $C_{38}H_{76}O_8$, m.p. 113.5°, iodine value 42.51; isogadoleic acid, $C_{20}H_{38}O_2$, m.p. 65.5° to 66°; a lactone-like substance, $C_{16}H_{32}O_2$, m.p. -11.6°; an acid, possibly arachidic acid; a brown resinous material insoluble in organic solvents; two unidentified solids probably acids. The presence of chaulmoogric and hydnocarpic acids, and these only, in the lighter fractions of the esters of the non-volatile acids is confirmed.—T. Hashimoto, *J. Amer. chem. Soc.*, 1925, 2325.

The characteristics of more than half the samples of commercial chaulmoogra oils examined approximate closer to those of *H. anthelmintica* or *H. Wightiana* than to those of *H. Kurzii*.—E. Andre, *C. R. Acad. Sci., Paris*, ii/1925, 1081, per *Quart. J. Pharm.*, 1926, 133.

Oil of *Hydnocarpus ilicifolia* (*Taraktogenos subintegra*) has been prepared from seeds grown in Siam; it has the following values: m.p., 23° to 28.2°, acid value as oleic acid 0.6%, sp. gr. 30°/4°, 0.947, saponification value 213.1, iodine value 89.7, n_D^{20} , 1.4763.—A. Marcon, *J. Soc. chem. Ind., Lond.*, 1926, 305T.

The oil employed in the treatment of leprosy is obtained from seeds of various species of *Hydnocarpus*. The chief amongst these are *H. Wightiana* Blume, *H. anthelmintica* Pierre and *H. Kurzii* Warb (= *Taraktogenos Kurzii* King). The last was formerly the chief source of the oil used in India, whilst *H. anthelmintica* of Indo-China and Siam was used in China. It has been found that the most effective oil is that of *H. Wightiana*, an Indian species, and this oil is the only one recognised in the B.P. Oil obtained from the seeds of *H. Wightiana* from Nigeria complied with the B.P. tests for purity but, possibly owing to its low free acid content, was not soluble in hot 90% alcohol. Oil from seeds grown in Ceylon also complied with B.P. requirements whilst oil from Malaya seeds had a saponification value of 205.1, but otherwise conformed.—*Bull. imp. Inst., Lond.*, 1936, 145.

Other oils of the Chaulmoogra group compared with the oil of *Hydnocarpus Kurzii* are:—

| Source | Sp. gr. | n_D | α_D | m.p. | Sap. value | Iodine value |
|---|------------|------------|------------|----------------|------------|--------------|
| <i>Hydnocarpus Kurzii</i> .. | 0.9425/32° | — | +48°00' | 33° to 39° | 210.4 | 96.1 |
| <i>Hydnocarpus anthelmintica</i> (Krabao Oil) | 0.9447/29° | 1.4755/29° | +58°10' | 26° to 29° | 191.0 | 90.0 |
| <i>Hydnocarpus anthelmintica</i> | 0.9427/32° | 1.4742/29° | +48°00' | 25° to 26° | 187.3 | 88.3 |
| <i>Hydnocarpus Wightiana</i> (Kavatel Oil) | 0.9330/32° | 1.4780/29° | +61°40' | 28° to 32° | 197.2 | 103.0 |
| <i>Hydnocarpus alpina</i> .. | 0.9346/32° | 1.4764/29° | +57°00' | 20.5° | 201.0 | 95.0 |

| Palmitic | 1.8 | 7.5 | 4.0 |
| Lower homologues of chaulmoogric acid .. | 3.4 | 0.1 | 0.4 |
| Loss | 0.4 | 2.2 | 1.0 |

—C. H. Cole and H. T. Cardoso, *Int. J. Leprosy*, 1941, 215.

Thiocyanate and Iodine Values. Fatty acids or glycerides with one double bond react towards thiocyanogen in the same way as towards iodine, but if they contain two double bonds, only one reacts with thiocyanogen, though both react with iodine. Thus the thiocyanogen value (expressed as iodine) of linolic acid is only half the iodine value. These values for chaulmoogra and hydnocarpus oils were:—

| | | |
|--------------------|--------------------|------------------------|
| Chaulmoogra Oil .. | Iodine value 100.6 | Thiocyanate value 99.1 |
| Hydnocarpus Oil .. | " " 95.7 | " " 94.8 |

indicating that little or no acids of the linolic series were present.—E. I. van Itallie, *Quart. J. Pharm.*, 1929, 618.

Ethyl Esters. The esterified oil of *Hydnocarpus Wightiana* when fractionated yields almost pure ethyl hydnocarpate; if chaulmoogra oil is used there is contamination with ethyl palmitate.—C. A. Perkins, A. O. Crusy and M. O. Riges, *Industr. Engng Chem., anal. Edn.*, 1927, 939.

Tests for Suitability of Hydnocarpus Oil for Injection. Various specimens of the oil have been examined physically and chemically in the Leprosy Department of the School of Tropical Medicine, Calcutta, and the findings correlated with the results of therapeutic tests on patients. Pain and other undesirable reactions following injection of the oil were found to be due to the use of oil which had been badly prepared, badly stored, or both. The oil should be expressed from sound, fresh, ripe seeds only. If the outer part of the seeds is not removed before expression the oil should be filtered as soon as possible since the presence of dirt and dust, as also exposure to air, light and moisture, favours oxidation and increase in acidity. Repeated sterilisation also aids oxidation and the oil should be sterilised once only. The acidity of a good oil, expressed as oleic acid, is not more than 1%, but an acidity of 3% is usually satisfactory; 3 to 5% of acid indicates a doubtful oil while with more than 5% the oil is usually poor. A test for peroxide gives a more reliable indication of the irritant properties of an oil than the determination of acidity. The following qualitative test is suggested: To 1 ml. of oil add 1 g. of solid potassium iodide and about 5 ml. of a mixture of glacial acetic acid and chloroform (2 : 1), shake and boil vigorously for 30 seconds. In the presence of a marked excess of peroxide a brown colour develops. If there is no appreciable colour, cool and add 10 ml. of 5% potassium iodide solution and 1 ml. of starch solution. The oil is not suitable for injection if the colour is deeper than light brown. The test can be modified so as to yield quantitative results by means of a titration with thiosulphate. The test for peroxides cannot be applied to solvent extracted oils or to oils which have been washed with sodium hydroxide solution.—J. Lowe and N. K. De, *per Leprosy Rev.*, 1938, 32.

OLEUM MORRHUÆ

Oleum Morrhuae (B.P. Add. I). Determined by the assay for vitamin A in relation to the Standard Preparation, contains in 1 g. not less than 600 units of vitamin A, and determined by the

biological assay of antirachitic vitamin (vitamin D) in relation to the Standard Preparation, contains in 1 g. not less than 85 units of antirachitic activity (vitamin D). Sp. gr., 0.922 to 0.929; n_{D40}^{20} , 1.4705 to 1.4745; acid value, not greater than 1.2; saponification value, 180 to 190; unsaponifiable matter, not more than 1.5%; iodine value, 155 to 173. Remains bright when kept at 0° for 3 hours. Oleum Morrhuae, U.S.P. XII, contains not less than 850 U.S.P. Units of vitamin A and 85 U.S.P. Units of vitamin D in each gramme. Complies with a test for stearin and a colour test when matched against a standard solution of cobaltous chloride and ferric chloride. It has a sp. gr. of 0.918 to 0.927 at 25° and an iodine value of 145 to 180; unsaponifiable matter, not more than 1.3%. The Fr. Cx. 1937 requires the oil to contain 600 International Units of vitamin A and 85 International Units of vitamin D, determined biologically. Vitamin A may be determined spectroscopically.

The percentage of unsaponifiable matter is a guide to purity, as oils likely to be used as adulterants mostly have high unsaponifiable matter. The lower limit for genuine cod-liver oil was 0.56% and the upper limit 1.5%, with an average of 1.07% determined on 150 samples representing 30,000 tons of oil.—C. C. Harris, *J. Soc. chem. Ind., Lond.*, 1938, 508.

Arsenic Content of twenty samples of crude American cod-liver oil from various producing centres was found to vary from 1.4 to 5.1 parts per million.—R. Remington, *Industr. Engng Chem., anal. Edn.*, 1934, 573.

Colour Standards. As the result of the examination of fifty-four samples two permanent colour standards, for light and dark oils, are suggested. For light oils, the oil when placed in a four-ounce cylindrical standard oil-sample bottle and viewed transversely shall not be more highly coloured than a solution placed in a similar bottle, containing 3.6 ml. of M/4 $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, 48.4 ml. of M/6 $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ and 68 ml. of distilled water. For dark oils the solution is, 11 ml. of M/4 $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, 76 ml. M/6 $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$, and 33 ml. of distilled water. The M/4 $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ solution contains 59.4965 g. of salt in 1000 ml. of 1% hydrochloric acid, the M/6 $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ solution contains 45.054 g. of salt in 1000 ml. of 1% hydrochloric acid.—A. Traub, *J. Amer. pharm. Ass.*, 1933, 194.

Nearly all samples of American cod-liver oil complied with the above standards but about one-third of the European oils were unsatisfactory as regards colour. Old oils which had been stored under unsatisfactory conditions were nearly all as pale as fresh oils, the acid values were however higher. As a rule dark oils have higher acid values than pale oils but there is no correlation between colour and acid value.—F. Tripp, *J. Amer. pharm. Ass.*, 1933, 1102.

Determination of Ultra-violet Absorption. The B.P. Add. II directs that the ultra-violet absorption is determined at 328 μ on a solution of the unsaponifiable matter in dehydrated alcohol or cyclohexane.

Viscosity of Cod-liver Oils. The viscosity is much influenced by temperature, so that appearance will not give an approximate estimation. When determined by the U.S.P. IX method for liquid paraffin the figures given for cod-liver oil at 25° are very uniform, nine brands of oil giving figures varying from 5.39 to 5.8 and ten successive batches from a single source 5.55 to 5.8.

Determination of Cod-liver Oil in Emulsions. To 10 g. of the emulsion is added 2.5 ml. of dilute sulphuric acid and the mixture shaken out twice with 20 and 20 ml. of chloroform, each time for two minutes. The chloroform is run into a small flask, dried with 1 or 2 g. of anhydrous sodium sulphate and filtered into a tared dish. The sodium sulphate and filter are washed twice with 5 ml. of chloroform. A current of dry air is drawn through the flask which is immersed in a water-bath. After the removal of the chloroform the residue is weighed.—R. Brieger, *Yearb. Pharm.*, 1913, 100.

To 10 g. of the emulsion is added 25 ml. of water and 5 ml. of alcohol. After gently warming, the mixture is shaken out with 30, 30 and 30 ml. of ethy ether.

The bulked ether extract is dried with anhydrous sodium sulphate, the solvent distilled from a tared flask, and the residue dried for 15 minutes and weighed.—C. Mannich and L. Schwedes, *Yearb. Pharm.*, 1913, 101.

A method using a modified cassia or Hirschon flask is described in *Yearb. Pharm.*, 1914, 235. Into an Erlenmeyer flask weigh 1 to 2 g. of emulsion, add 10 ml. of 12.5% hydrochloric acid and a small piece of pumice, heat gently over a wire gauze until a clear solution results, partly closing the flask with a small funnel. Pour the warm liquid into a 100 ml. cylinder (graduated to 0.5 ml.) and having an internal diameter of 2 cm., wash out the flask, after cooling, with 30 ml. each of ether and petroleum ether, adding these solvents to the contents of the cylinder and shaking vigorously. After standing 1 to 2 hours, note volume of ethereal solution, withdraw 50 ml. to a tared 150 ml. round-bottom flask, washing out the pipette with petroleum ether. Distil off the ether and petroleum ether, dry at 100° and weigh.—G. Buemning, *Yearb. Pharm.*, 1915, 262.

10 g. of the diluted emulsion (1 in 10) is mixed with 2 ml. of solution of ammonia, 10 ml. of dehydrated alcohol, 20 ml. of ethyl ether and 20 ml. of petroleum ether, well shaking after the addition of each. Allow to stand for 15 minutes, draw off the aqueous liquor and shake the ethereal layer with 0.6 g. of tragacanth. After clearing, the ethereal liquid is filtered into a tared beaker, the tragacanth washed with two portions, each of 5 ml., of petroleum ether which is also filtered into the beaker. The combined ethereal liquors are evaporated, the residue dried at 100° to constant weight.—Scriba, *Yearb. Pharm.*, 1915, 262.

The determination, if carried out in a Soxhlet, is unsatisfactory because of the oxidation which occurs when the emulsion is mixed with sand and dried. Satisfactory results may be obtained by a modification of the Rose-Gottlieb method. 10 g. of the emulsion is heated for ten minutes with 10 g. of 25% hydrochloric acid, cooled, transferred to a separator, rinsed in with 10 ml. of alcohol followed by 3 portions each of 10 ml. of a mixture of equal parts of ether and petroleum ether. 50 ml. of water is added and the bottle shaken vigorously. After separation, run off the aqueous liquid and add 1 g. of tragacanth. The oil solution is dried at 100° and weighed.—Valentin, *Quart. J. Pharm.*, 1932, 78.

Determination of Cod-liver Oil in Malt and Oil. The method is based on the fact that the sp. gr. of cod-liver oil is less than that of water and that of malt extract is considerably greater, and further that the sp. gr. of a 50% solution of malt extract is, within small limits of error, proportional to the n_D of the malt extract itself. Equal weighed quantities of the sample and water are mixed and the sp. gr. determined at 20°. The sp. gr. may be corrected by adding 0.0006 for each 1° above if taken at over 20°. The n_D is determined at 20°, correcting by the addition of 0.00018 for each 1° if taken at over 20°. The percentage of oil is calculated from the formula:—

$$(n_D - 1.3332) \times 549.6 - \frac{(d-1)}{d} \times 584.8.$$

—H. D. Richmond and F. G. Hitchman, *Yearb. Pharm.*, 1917, 75.

Use 4 to 6 g. of the sample, add 15 ml. of water, mix, add 50 ml. of ethyl alcohol, place in a 250 ml. separating funnel and shake until the emulsion breaks, add 50 ml. of low boiling petroleum ether and shake for a few minutes, separate the hydro-alcoholic solution and the petroleum ether solution into two beakers. Replace the hydro-alcoholic solution in the separator and repeat the extraction with petroleum ether four or five times. Evaporate the combined petroleum ether extracts. Dry the residue in a desiccator over sulphuric acid to constant weight.—C. S. Waggoner and C. C. Glover, *J. Amer. pharm. Ass.*, 1926, 754.

Gunn-Venables Method. In order to overcome the formation of emulsions when the diluted malt preparation is shaken with ether and to avoid loss of vitamin A from the oil, weigh accurately 5 to 10 g. into a beaker and mix with distilled water (3 ml. for each gramme taken). Add 8 parts of dehydrated alcohol to each 5 parts of the above dilution (industrial methylated spirit may be used) and 0.4 g. of purified kaolin. Stir thoroughly and allow the precipitate to settle. Filter the clear liquid and add 50 ml. of 70% alcohol to the precipitate, again stir and allow to settle. Filter the clear liquid through ordinary grade paper, and collect the residue on the filter, washing out the

beaker with 70% alcohol. When the precipitate has drained release any water from the stem of the funnel, and wash the residue with ether, collecting the ether in a separating funnel. Any precipitate adhering to the paper should be detached with a glass rod. Continue washing with ether until a drop shows no film on evaporation, about 160 ml. being necessary. Wash the ether in the separator with three portions of 30 ml. of distilled water and transfer to a distilling flask. Distil off the ether and transfer the residue to a weighed beaker, washing out the flask with a little ether. Add a few ml. of dehydrated alcohol, evaporate, cool and weigh. The oil may then be tested by the methods of the *B.P.C.*—Gunn and P. F. R. Venables, *Quart. J. Pharm.*, 1936, 430.

Rose-Gottlieb Method. Of various methods considered, the Rose-Gottlieb and Gunn-Venables methods were found to be most suitable. With fresh materials both methods gave results that agreed well and afforded an accurate measure of the oil-content, but with increase in age of the preparation the latter method gave low results. The vitamin A content of the extracted oil was determined spectrophotometrically and it was shown that full recovery could be obtained when the Rose-Gottlieb method of extraction of the oil was used, provided that precautions were taken against oxidation. The details of the method are as follows. Disperse about 5 g. of the preparation in 5 ml. of water and transfer the mixture to a stoppered 100-ml. tube by means of a further 5 ml. of water. Add 1 ml. of ammonia solution (sp. gr., 0.880) and 5 ml. of alcohol followed by 20 ml. of ether, using part to rinse in any oil possibly remaining in the original weighing vessel. Stopper and shake vigorously for two or three minutes. Add 20 ml. of light petroleum (40°–60°) and shake again. Centrifuge, siphon off the solvent layer into a tared flask and repeat the shaking and extraction with about 15-ml. portions of ether and light petroleum. Evaporate, re-evaporate after addition of a few ml. of alcohol or acetone, dry and weigh the oil. Precautions must be taken against oxidation such as evaporating in an atmosphere of nitrogen and keeping ethereal solutions under nitrogen. In determining the vitamin A content, the oil was not dried, but immediately saponified with alcoholic potash for a maximum of five minutes. The unsaponifiable matter was extracted by the method given in the *B.P. Add. I*, and the solution obtained evaporated under nitrogen. A few ml. of pure acetone were added, the liquid re-evaporated and the unsaponifiable matter cooled in nitrogen. It was dissolved in spectroscopically pure cyclohexane, diluted to a suitable volume and immediately examined spectrographically.—D. C. Garratt, *Analyst*, 1939, 795.

The following details for the Rose-Gottlieb method for the determination of oil are recommended by the Sub-Committee on the Assay of Galenicals of the Committee on Pharmaceutical Chemistry:—Mix about 2.5 g., accurately weighed, with 5 ml. of water and transfer to a 100-ml. stoppered cylinder, using a further 5 ml. of water. Add 5 ml. of alcohol (95%), 1 ml. of strong solution of ammonia and 25 ml. of ether. Shake vigorously for a few minutes; add 25 ml. of light petroleum (boiling-point, 50° to 60°); shake and allow to stand until the ethereal layer is quite clear. Siphon off the ethereal layer; add 20 ml. of ether to the residual aqueous layer and shake vigorously; add 20 ml. of light petroleum (boiling-point, 50° to 60°). Shake and allow to stand until the ethereal layer is clear. Siphon off the ethereal layer and repeat the extraction, using a further 20 ml. of ether and adding 20 ml. of light petroleum (boiling-point, 50° to 60°). Mix the ethereal solutions and remove the solvent by evaporation on a water-bath in an atmosphere of nitrogen; dry the residue in an atmosphere of nitrogen at 100° and weigh.—(*British Pharmacopœia Commission Report*, No. 11, May 1939.)

Werner-Schmidt Method. In the determination of oil in extract of malt with cod-liver oil the low results obtained by the Gunn and Venables method are due to the almost quantitative solubility of the fatty acids in the alcohol used, the figure obtained for extracted oil being that of neutral oil only. It was found that the acidity of the oil in extract of malt with cod-liver oil increases, in some cases, to an extraordinary degree. In thirty samples examined the free acidity of the extracted oil calculated as clupanodonic acid varied from less than 2.5% in six samples to above 10% in seven samples. For the determination of the total fatty matter the Werner-Schmidt method modified as follows was used:—Disperse about 2.5 g. of extract of malt with cod-liver oil in 15 ml. of warm water, add 15 ml. of concentrated hydrochloric acid, transfer to a 200 ml. separator, washing in with 10 ml. of water and 50 ml. of ether. Shake and

separate; re-extract the aqueous layer with 30 ml. of ether. Wash the combined ether extracts free from mineral acid, re-extract the washings with ether, bulk the ethers, evaporate, re-evaporate twice with a little acetone and dry in a desiccator for half-an-hour before weighing.

The extracted oil is titrated for free acidity in the usual way. The method is not suitable for routine analysis as persistent emulsions are liable to be formed which are eliminated with difficulty. A limit of 5% acidity in the oil is suggested for the *B.P.* preparation.—D. C. Garratt and J. E. Woodhead, *Quart. J. Pharm.*, 1941, 14, 172–175.

A tentative method for the determination of cod-liver oil in emulsions. The sample is mixed with calcium carbonate and extracted with chloroform. The chloroformic extract is evaporated and the oil weighed.—*Methods of Analysis (A.O.A.C., 1940, 625).*

THE VITAMINS OF COD-LIVER OIL

Cod-liver oil contains vitamins A and D in varying amounts. Most samples of cod-liver oil have a vitamin D potency between 60 and 150 international units per gramme; occasionally samples are found to have 300 or 350 units per gramme. The vitamin A potency ranges from about 1000 to 3500 international units per gramme, though occasionally samples are found to have a lower or a higher value than these.

There is no correlation between the vitamin A and the vitamin D values of a sample of cod-liver oil. The following table of values found for 23 samples of cod-liver oil in the Pharmaceutical Society's Laboratories shows this:—

Vitamin A and D Value of Twenty-three Samples of Cod-Liver Oil Examined Biologically

| Sample | Vitamin A International Units | Vitamin D International Units |
|--------|----------------------------------|----------------------------------|
| 1 | 1,500 | 160 |
| 2 | 1,500 | 360 |
| 3 | 500 | 80 |
| 4 | 650 | 85 |
| 5 | 1,500 | 210 |

The vitamin value of cod-liver oil seems to vary inversely with the yield of oil from any particular liver or batch of livers. The origin of the vitamins in cod-liver oil is almost certainly the diet of the cod, namely herring, whiting, codlings in the North Sea, and squid and caplin round the Newfoundland banks. Since, however, these have only a low vitamin content, it must be concluded that the cod itself uses little of the vitamin obtained from its food but stores it in the liver for some unknown reason.—Drummond and Hilditch, *Empire Marketing Board Publication, No. 35, 1930, H.M.S.O.*

The oil obtained from the liver of the soup-fin shark (caught off the Pacific Coast of the U.S.A.) has a higher vitamin A potency than that of almost any other fish, amounting, for example, to more than 30 times that of cod. More

than 60% of the national production of vitamin A in the U.S.A. in 1940, i.e., 25 billion units, were manufactured from this source.—*Chem. & Drugg.*, ii/1942, 205.

Blue values determined by the B.P. method on 67 oils purchased from retail chemists were obtained ranging from 3.5 to 20.0 and the average was 7.8. The average blue value obtained on 36 samples via the unsaponifiable matter was 27.0. The best values for average oil are:—direct blue value=9.3; blue value via unsaponifiable matter=21.8. The best values obtained by spectrophotometric examination are:—extinction coefficient (1% solution in 1 cm. cell) at $328\text{ m}\mu=0.587$ (on oil) and 0.505 (via unsaponifiable matter); percentage of vitamin A=0.0315. The biological assays of bulked samples gave the following results:—vitamin A=670 units per gramme; vitamin D=81 units per gramme.—R. S. Morgan and H. Pritchard, *Analyst*, 1935, 357.

An Alternative Colorimetric Method. The determination of vitamin A in cod-liver oil can be made by a colour test in which the oil is heated with a chloroform solution of catechol and antimony trichloride. The violet-red colour obtained is compared as soon as it is formed with a 0.01% solution of potassium permanganate. The colour is said to be more stable than the blue colour obtained with antimony trichloride alone.—E. Rosenthal and J. Erdélyi, *Biochem. J.*, 1934, 28, 41.

Effect of Light on Vitamin A Potency. Exposure of cod-liver oil to any source of white light of sufficient intensity results in "delumination"—disappearance of normal golden fluorescence—and destruction of vitamin A. Kept for some months in the dark it regains much of its fluorescence but vitamin A is permanently destroyed.—P. R. Peacock, *Lancet*, ii/1926, 329.

Cod-liver oil emulsions can be kept for at least 4 months without appreciable loss of vitamin A potency, and probably for 7 or 8 months without serious alteration, if stored in well-stoppered, amber glass bottles and kept in the dark.—H. N. Griffiths, T. P. Hilditch and J. Rae, *Analyst*, 1933, 65.

Unsaturated Fatty Acids in the Oil. Cod-liver oil is composed almost entirely of unsaturated fats. An increase in the amount of unsaturated fatty acids in the environment of the tubercle bacillus tends to disintegrate it. An increase of unsaturated fatty foods yields an increase of the same in the blood, and the bacillus is present in the blood in comparatively early cases of phthisis. Increase of saturated fat above a certain point retards its absorption from the intestine. The saturated fat is assimilated up to about 14% only; unsaturated, on the other hand to the extent of 98%. In a mixed diet the unsaturated help the saturated to become absorbed. The highly unsaturated acids serve the immediate needs of energy production and the saturated are stored in the nature of a reserve.

Cod-liver oil should be prepared under conditions preventing oxidation, both from the aspect of this theory and the vitamin content.

Cod-liver oil is a food—it enters into permanent combination with a body cell yielding energy to it and altering the whole of the cell's relations by becoming an integral part of the cell protoplasm. It is more readily absorbed than other fats and has probably a marked action on metabolism.

A part of the fat obtained from animal tissues is not real fat, but complex combinations of fatty acids with glycerophosphoric acid and nitrogen-containing compounds—the so-called phosphatides—this is the portion actually made use of by living cells. Phthical patients treated with cod-liver oil have been observed and effects on *nitrogen metabolism* found to be marked and the beneficial effect on *fat absorption* to be considerable.

The total activity of cod-liver oil does not reside in its vitamin D, or in A+D, any more than quinine represents the total activity of cinchona bark. Attention is drawn to the phosphatides and the high content of *unsaturated fatty acids*.—J. W. England, *J. Amer. pharm. Ass.*, 1929, 116.

British Standards Specifications for veterinary cod-liver oil and for whale oil have been prepared as follows:—

B.S.S. No. 839—1939, relates to veterinary cod-liver oil and includes requirements regarding description, colour, sp. gr. (0.922 to 0.929), refractive index for the D line at 20° (1.478 to 1.482), iodine value (150 to 178), acidity (not to exceed 1% unless otherwise declared, and in no case to exceed 3% expressed as oleic acid), unsaponifiable matter, vitamin potency (not less than 500 i.u. of vitamin A and 50 i.u. of vitamin D), blue value (not less than 6) and sampling.

B.S.S. No. 836—1939, relates to whale oil and includes requirements regarding description, moisture and dirt, colour, saponification value (182 to 205), acidity (not more than 6% calculated as oleic acid), unsaponifiable matter and sampling.

See also under Vitamins, p. 760

Oleum Morrhue Non-Destearinatum (U.S.P. XII). Contains not more than 0.5% *v/v* of water and liver tissue, not less than 850 *U.S.P.* Units of vitamin A and 85 *U.S.P.* Units of vitamin D in each gramme; iodine value, 128 to 180.

Sodii Morrhuas (B.P. Add. IV). Forms a clear solution in 10 parts of warm water. Iodine value of fatty acid, 140 to 175. It complies also with limit tests for alkali hydroxide or free fatty acid, alkali carbonate and oxidised fatty acids.

Comparison of five samples showed that "Sodium Morrhuate 10%" is very differently interpreted by different makers and that some standards should be laid down and conformed to. Iodine value varied from 148 to 226.5, colour from clear yellow to turbid orange, and fatty acid content from 7.0 to 9.45%. —R. T. M. Haines, *Lancet*, i/1933, 748.

Liquor Vitaminæ A (B.P.C.). Contains in 1 g. approximately 60,000 units. The unit is the activity of 0.0006 mg. of a sample of β -carotene kept in the National Institute for Medical Research, London, and adopted as the international standard.

OLEUM OLIVÆ

Oleum Olivæ (B.P.). Sp. gr., 0.915 to 0.918; n_{D40}^{20} , 1.4605 to 1.4635; acid value, not more than 2.0; saponification value, 190 to 195; iodine value, 79 to 88. Complies with tests for absence of sesame oil, cottonseed oil and arachis oil. The *B.P. Add. I* alters the test for sesame oil—equal volumes of the oil and an alcohol (90%) and strong solution of ammonia mixture (9 : 1) are shaken and the alcohol and ammonia evaporated on a boiling water-bath; the oil is then shaken with half its volume of 1% sucrose in hydrochloric acid; after 5 minutes in the acid layer there should be no pink or no deeper pink than a control test without sucrose. The *Fr. Cx.* 1937, in testing for arachis oil, separates the ether-insoluble lead soap from 20 g. of oil and dissolves the regenerated fatty acid in 100 ml. alcohol (90%) with one drop of dilute hydrochloric acid; the crystals forming in the solution on cooling have a m.p. of 70° to 75°. Sesame oil is excluded by adding to 2 or 3 drops of 2% furfural in alcohol (95%) solution 10 ml. of the oil followed by 10 ml. of hydrochloric acid—the separated acid should not be coloured red. Olive oil should be decolorised by warming to 50° with animal charcoal before testing for cottonseed oil, and the reaction tubes are immersed in boiling brine for a longer period. The *U.S.P. XII* oil has a sp. gr. of 0.910 to 0.915 at 25° and an iodine value of 79 to 88; solidification point of the fatty acids, 17° to 26°.

The *B.S.S. No. 630—1935* does not differentiate between virgin and refined olive oils. It includes requirements regarding description, colour, specific gravity, refractive index (1.468 to 1.471 at 20°), iodine value, saponification

value, acidity and unsaponifiable matter, and gives details of the tests to be applied for the absence of arachis, sesame and cottonseed oils.

Prevention of Deposit. The addition of 0.1 to 0.5% of air-blown cacao butter to olive oil enables the oil to be stored for long periods at 2° without any deposition of stearin. The addition has no effect on arachis or cottonseed oils.—W. Clayton *et al.*, *Nature, Lond.*, ii/1936, 801.

Tea-seed Oil as an Adulterant of Olive Oil has received considerable attention. Tea-seed oil was investigated and figures published in "Tea-seed oil and its uses as an adulterant of olive oil," H. A. Caulkin, *Yearb. Pharm.*, 1927, 616. As a result the following was stated: "The result of our investigation is to show that it is impossible either from a consideration of the available chemical and physical constants of an olive oil, or by means of any of the colour tests hitherto suggested, to ascertain whether such an oil is adulterated with tea-seed oil." This is further confirmed by N. Evers (*Pharm. J.*, i/1933, 195): "It is impossible, therefore, in the present state of knowledge to write a monograph on cod-liver oil or olive oil and give standards which will prevent the addition of adulterants. In these cases we have to rely on the statement at the head of the monograph that the oil is 'the oil obtained from . . .'"

Spectroscopic Detection. The extinction coefficient of olive oil at a wave-length of 268 μ is 11 whilst that of tea-seed oil is 690 and a mixture of olive oil with 5% of tea-seed oil is 46.—S. Judd Lewis, *Analyst*, 1935, 10.

Spectroscopic examination of a number of samples of tea-seed and olive oils showed a considerable variation, which completely vitiates the value of test given by Judd-Lewis.—W. F. Elvidge, *Quart. J. Pharm.*, 1941, 147.

A Colorimetric Method which is specific for tea-seed oil is as follows: Measure into a test-tube 0.8 ml. acetic anhydride, 1.5 ml. chloroform, and 0.2 ml. concentrated sulphuric acid, mix, cool to room temperature and add, by means of a test tube of 4 mm. external and 2 mm. internal diameter, 7 drops of the oil to be tested. If the mixture is cloudy it is cleared by the addition of acetic anhydride drop by drop, with shaking between each addition. After 5 minutes at room temperature the colour is noted. Tea-seed oil gives a deep green by reflected and brown by transmitted light, and olive oil green by reflected and transmitted light, with occasional faint fluorescence. 10 ml. of anhydrous ether is then added from a graduated cylinder and the contents of the tube mixed by one inversion. Tea-seed oil shows a brown colour changing after a minute or so to intense red, reaching a maximum after a few minutes then fading. Olive oil gives an intense green, slowly fading to brown-grey occasionally passing through faint pink. Mixtures show the tea-seed oil colour in proportion to the amount present. By controlling the conditions in ice-water the test may be made approximately quantitative.—J. Fitelson, *J. Ass. off. agric. Chem., Wash.*, 1936, 493. (This method is now official in *Methods of Analysis, A.O.A.C.*, 1940, 440.)

A collaborative study of the Fitelson test (see previous abstract) confirms its accuracy as a method for determining tea-seed oil in olive oil even when the test is carried out by those having no previous experience of it. No red colour is given by any of 9 other seed oils examined.—G. S. Jamieson, *ibid.*, 1937, 418.

Chloroform and acetic anhydride are mixed, cooled in an ice-bath, and 0.8 ml. of a freshly-prepared mixture of 10 ml. glycerin in 100 ml. concentrated sulphuric acid added with constant shaking and cooling. The mixture is left for one hour at room temperature shaking every five minutes until no further separation occurs, cooled to 0° for five minutes and then 3 ml. of water added very slowly. After 5 to 10 minutes a dark green colour appearing in the first stages of the test persists in the case of olive oil but changes to a fugitive dark red at the end in the case of tea-seed oil. Mixtures give intermediate colours, the red-brown being recognisable with 5% of tea-seed oil in olive oil. Strongly rancid olive oil and cottonseed oils give red reactions, and sesame oil, but not arachis oil, may interfere with the test.—W. Siebenberg and W. S. Hubbard, *Quart. J. Pharm.*, 1937, 242.

Fitelson's method may be made quantitative by following the original directions, by cooling the 10 ml. of ether in ice-water and then after mixing the reagents and oil, allowing 4 minutes contact, and finally immersing the tube in ice-water; under these conditions the colour develops more slowly, attaining its maximum intensity after 45 minutes and remaining stable for 5 minutes. Comparison may be made, against a background of white paper, with tubes containing potassium permanganate solution, since it is found that 10% of tea-seed oil gives a colour very close to that of 0.1 ml. of an N/10 potassium

permanganate solution in 100 ml. of water, and 20% corresponds with 0.225 ml. of the permanganate in 100 ml. of solution. On applying the reaction to samples of olive oil of different origin it was found that authentic samples from Tébourba and Ghardinaou in northern Tunisia showed more or less pronounced colour reactions, although all other samples gave negative results. Hence before concluding an olive oil to be adulterated with 10 to 15% of tea-seed oil, the source of the oil should be ascertained.—R. Marcille, *Ann. Falsif.*, 1939, 32, 172.

Some pure olive oils give the colour reaction for cholesterol with acetic anhydride, sulphuric acid and chloroform equivalent to about 10% of tea-seed oil. The test is modified so that tea-seed oil gives a red colour and olive oil a bluish-green colour for all types of the latter. 10% of tea-seed oil can be detected.—W. H. Dickhart, *Amer. J. Pharm.*, 1940, 112, 371.

A modification of the Fitelson test which obviates the positive reaction given by some genuine oils is as follows:—Acetic anhydride 1 ml. is shaken with 2 ml. chloroform and 0.2 ml. conc. sulphuric acid and when the temperature of the mixture is about 40°, 10 drops of oil are added, shaken and then 0.1 ml. syrupy phosphoric acid added. The mixture is kept at 23° to 25° in a water-bath for 10 to 15 minutes and, after addition of 5 ml. of ether (distilled over sodium), is cooled in ice-water until the colour forms. Tea-seed oil gives a red and olive oil a bluish-green colour. The test will detect as little as 10% of tea-seed oil. After the red colour due to the tea-seed oil has disappeared, 1 ml. of acetic anhydride is added and then 20 more of the oil. Conc. sulphuric acid 2.6 ml. is carefully added and the liquid slowly and cautiously mixed. After one minute, the mixture is cooled, 5 ml. of ether are added and the mixture is warmed in water at 25°. The red colour given by tea-seed oil will replace the green first given by the olive oil and will sometimes persist for two hours. The best results are given by reagents free from alcohol and water. The author is of the opinion that oil of pharmacopœial standard should not give a red colour.—W. H. Dickhart, *Analyst*, 1941, 69.

The Iodine Value of the Unsaponifiable Matter (Bolton-Williams number) of oils enables them to be divided into four main groups. Olive oil lies in a group alone and is distinguished from other oils and in particular from tea-seed oil. The unsaponifiable matter is prepared as follows: From 2 to 2.5 g. of oil are saponified by boiling under a reflux condenser with 25 ml. of N/2 alcoholic potash. The solution is titrated with N/2 hydrochloric acid using phenolphthalein as indicator. 5 ml. of N/2 sodium hydroxide is added and the solution is extracted three times or more with 30 to 40 ml. of petroleum ether. The combined extracts are washed with 20 ml. of N/20 sodium hydroxide and then with 20 ml. of water and filtered into a weighed flask, the petroleum ether is distilled off, and the contents dried and weighed. The quantity obtained will vary between 0.01 and 0.04 g. In obtaining the iodine value the Wijs method gives erratic results whilst the Hübl method gives fairly constant figures; the method of Rosenmund and Kuhnhehn is, however, simpler. The N/10 pyridine-sulphate-bromide reagent is made as follows: Mix 8 g. of bromine with 20 ml. of glacial acetic acid and, separately, add gradually 10 g. of concentrated sulphuric acid to 8 g. of pyridine in 20 ml. of glacial acetic acid, cooling during mixing. The two solutions are mixed and made up to 1 litre with glacial acetic acid. The unsaponifiable matter obtained as above is dissolved in 5 ml. of chloroform and sufficient of the pyridine reagent added to leave an excess of about 50%, usually about 10 ml. Allow to stand in the dark for 5 minutes, then add 5 ml. of 10% potassium iodide solution and 40 ml. of water. The liberated iodine is titrated with N/20 thiosulphate solution. A blank experiment is carried out at the same time. The amount of halogen absorbed is calculated as iodine as a percentage of the weight of the unsaponifiable matter, in the same manner as in the Wijs method. The method given above for the preparation of the unsaponifiable matter must be adhered to in order that it may be of the correct degree of purity. The result falls into one of the following groups:—

- | | | |
|----------|--------------------------|--|
| Group 1. | Iodine value 64 to 70. | Animal fats and a few vegetable fats. |
| Group 2. | Iodine value 90 to 96. | Fish and marine animal oils, cocoa butter. |
| Group 3. | Iodine value 117 to 124. | Vegetable oils and fats. |
| Group 4. | Iodine value 197 to 206. | Olive oil only. |

The high value of olive oil as compared with those of oils used as adulterants, mostly in group 3, makes it possible to detect as little as 10%, which will reduce

the value below the minimum.—E. R. Bolton and K. A. Williams, *Analyst*, 1930, 5.

Elaidin Test. A modification of this test in which the elaidin is prepared and then crystallised from acetone, is performed as follows. 10 to 20 g. of the oil is shaken with mercury 0.2 to 0.4 g. and nitric acid 0.5 to 1.0 ml. in a stoppered bottle immersed in water at room temperature for one hour, and then left to stand overnight. The product is dissolved in ether, washed with dilute nitric acid to remove mercury compounds, and then with water until free from acid. The ether and moisture are removed by evaporation and the residue finally heated at 95° for a short time. 5 g. of the dried product is crystallised from 20 ml. of acetone, the solution being kept at room temperature overnight and finally cooled at 0° for two hours. The separated crystals are collected, washed four times with acetone, 5 ml. each washing, dried in a desiccator and weighed. The m.p., iodine value and saponification value are then determined. Olive oil yields 33.1 to 35.5%, m.p. 33.5° to 37.0°, iodine value 67.1 to 68.8, saponification value 196.1 to 197.0. These figures do not differ sufficiently from those of tea-seed oil to enable its presence in olive oil to be detected, but they are widely different from cottonseed oil and show a distinct difference in the saponification value from ground nut oil which is 189.4 to 189.9.—H. N. Griffiths and T. P. Hilditch, *Analyst*, 1934, 312.

Detection of Sesame Oil. A sample of genuine Portuguese olive oil gave a distinct colour with the hydrochloric acid and furfural test of the Belgian Pharmacopœia. Soltsien's test gives a reddish-violet colour with more than 1% of sesame oil. The oil is shaken with an equal volume of a 10% solution of stannous chloride in 38% hydrochloric acid, warming to produce separation.—P. Deltour, *Quart. J. Pharm.*, 1935, 252.

The Detection of Arachis Oil in Olive and Almond Oils.

A modification of the B.P. sorting and confirmatory test which will detect the addition of 5% of arachis oil is performed as follows: 1 ml. of oil is saponified with 5 ml. of 1.5 N alcoholic potassium hydroxide solution by heating on a water-bath for five minutes, avoiding loss of alcohol; 50 ml. of 70% alcohol is added, followed by 0.8 ml. of hydrochloric acid (sp. gr. 1.16). After heating to dissolve any precipitate that may be formed, the solution is cooled in water, stirring continuously with a thermometer, so that the temperature falls at the rate of about 1° per minute. If turbidity appears before the temperature reaches 9°, the usual confirmatory test for arachis oil must be applied; if the oil remains clear at this temperature, arachis oil may be regarded as absent.—N. Evers, *Analyst*, 1937, 62.

The Fluorescence Test. The published statements concerning the nature of the fluorescence of olive oil in filtered ultra-violet light are somewhat contradictory. Crude oils from Spain and Italy give an orange fluorescence whilst the addition of more than 15% of French oil causes a green fluorescence to develop, virgin Apulian oils give lemon-yellow to orange, and refined oils give sky-blue. Oils have been offered in the market giving opaque purple or chocolate coloured fluorescences which may be due to adulterants or refined oil. When genuine virgin olive oil exhibiting a deep golden yellow fluorescence was treated repeatedly with decolorising charcoal (five 1 g. portions per 100 ml. of oil) and filtered, the resulting oil was almost white and showed only the faintest dull blue fluorescence. Arachis, sesame, tea-seed and refined olive oil were bleached, but retained their original blue fluorescence. An oil giving a low Bolton-Williams number invariably exhibits a bright-blue fluorescence after decolorising and should be regarded with suspicion.—T. T. Cocking and S. K. Crews, *Quart. J. Pharm.*, 1934, 531.

An objection to the fluorescence test is that the blue fluorescence, characteristic of refined oils, disappears when pigments such as carotene or chlorophyll are added. The spectra of virgin oils under light produced by a mercury arc shows an intense blue-violet band at 380.0 to 460.0 $m\mu$, a less intense yellow-green band at 510.0 to 590.0 $m\mu$, and an intense red band at 640.0 to 660.0 $m\mu$. If the same oil decolorised or a refined oil is examined, the blue-violet band is very sharp and the yellow is intensified, but the red band is absent.—J. Guillot, *Analyst*, 1935, 432.

Retarding Oxidation. Ultra-violet rays have been found to be mainly the cause of the acceleratory action of light on the oxidation of oil. Deep red cellophane found to give the best protection, followed in diminishing value by orange, violet, grass green and lemon yellow.—H. L. G. Barton and A. Davis, *J. Soc. chem. Ind.*, 1939, 58, 189.

Oleum Rapæ (B.P.C.). Sp. gr., 0.913 to 0.917; $n_{D40^{\circ}}$, 1.463 to 1.467; acid value, not more than 5; saponification value, 171 to 177; iodine value, 97 to 105; unsaponifiable matter, 0.6 to 1.2%.

The B.S.S. No. 631—1935 for rape seed oil gives requirements for specific gravity (0.913 to 0.916), refractive index at 20° (1.4720 to 1.4735), iodine value, saponification value, acidity, unsaponifiable matter, viscosity (Redwood scale, not lower than 390 at 70°F. , or 0.917 poise) and flash point (Pensky-Martens, not below 400°F.).

Determination of Rape and Mustard-Seed Oils. Erucic acid is the characteristic unsaturated acid peculiar to these oils. The percentage of iodine absorption of the solid fraction separated under standard conditions, expressed in terms of erucic acid, may be used as a guide to estimation of purity. 500 to 510 mg. is weighed in a 50 ml. Erlenmeyer flask and saponified with 5 ml. of alcoholic potash (40 ml. of potash solution (sp. gr. 1.5) and 40 ml. of water made up to 1 litre with 95% alcohol) for one hour on a water-bath under an air condenser. The solution is treated with 20 ml. of lead acetate solution (50 g. lead acetate, 5 ml. of 95% acetic acid made up to 1 litre with 80% v/v alcohol), 3 ml. of water and 1 ml. of 96% acetic acid, and the mixture heated under a reflux condenser until the lead salts are dissolved. It is then gradually cooled to room temperature and kept in an incubator at 20° for 14 hours. It is then transferred to a sintered glass crucible (3G/10, Schott, and Gen) by means of 70% alcohol (cooled to 20°) and the precipitate washed with 12 ml. (in small portions) of the cooled alcohol that had previously been used for rinsing the flask. The precipitate is dissolved in 20 ml. of a hot mixture of equal parts of 95% alcohol and 96% acetic acid in a tall 150 ml. beaker, covered with a watch glass. The warm solution of lead salt and the crucible are washed into a 350 ml. glass-stoppered Jena glass bottle with 10 ml. of mixed alcohol and acetic acid. The iodine value of the lead salt is then determined by the method of Margosches, Hinner and Friedmann, *Z. angew. Chem.*, 1924 37, 334, in which 20 ml. of freshly prepared N/5 alcoholic iodine solution is added, shaken with 200 ml. of distilled water and kept in the dark for one hour, and finally titrated with N/10 thiosulphate solution. A blank of 30 ml. of mixed acetic acid and alcohol is titrated and used as a correction. The "value" is the percentage of iodine absorption in terms of erucic acid, 1 ml. of N/10 thiosulphate = 16.9 mg. of erucic acid. The following values were found:—

| | |
|---|--------------|
| Oil of <i>Brassica juncea</i> | 43.8 to 46.9 |
| Oil of <i>Brassica napus</i> | 45.7 to 47.2 |
| Oil of <i>Brassica campestris</i> | 43.8 to 48.8 |
| Arachis Oil | 1.32 to 1.7 |
| Linseed Oil | 1.6 to 1.8 |
| Sesame Oil | 1.8 to 2.1 |
| Niger-seed Oil | 2.2 to 2.4 |
| Cottonseed Oil | 1.4 to 1.7 |
| Castor Oil | 0.2 to 0.3 |

—S. Neorgi, *Analyst*, 1936, 597.

A method almost identical with the above is used for the estimation of rape oil in edible oils. The presence of 5% or less of rape oil may be detected by absorption of the lead salt upon lead palmitate. For this purpose 0.25 g. palmitic acid is mixed with 0.5 g. of the oil to be tested and 7.5 ml. of the alcoholic potash used for saponification. To the soap solution are added 2 ml. of 96% acetic acid, 30 ml. of alcoholic lead acetate solution and 5 ml. of water. The mixture is warmed, allowed to stand overnight and the precipitate filtered off and treated as above.—J. Grossfeld, *Analyst*, 1936, 124, and 1937, 561.

The characteristic sterol of rape seed oil is brassicasterol, m.p. 148° , which has been shown to consist of 7:8-dihydroergosterol.—E. Fernholz and H. E. Staveland, *J. Amer. chem. Soc.*, 1940, 1875.

Turtle Oil. The commercial oils are generally obtained from the muscles and genital glands of the giant sea-turtle. There are several varieties of oil on sale. A bulk of four separate samples of West African oil had the following characters:—Solid at ordinary temperature, light yellow colour, mild but distinct odour, melted to a golden-yellow coloured oil. It bleached on exposure to light. M.p., 24.6° incipient fusion, 25.6° final fusion; solidifying point, 22.5° ; titre, 25.5° ; sp. gr., 0.9112/40°; $n_{D40^{\circ}}$, 1.4599; saponification value, 209; unsaponifiable matter (S.P.A. method), 0.6%; iodine value of unsaponifiable

matter (Bolton-Williams method), 92.5; iodine value, 64.6; acid value, 2.0; percentage of insoluble bromides on the free acids (Gemmel's method), 5.0; m.p. of the bromides, darken above 200°; Reichert-Meissel value, 0.2; Polenski value, 1.7; Kirschner value, 0.06; acetyl value, 3.5. Other samples of oil gave the following figures:—

| Variety of Oil | $n_{D_{40}^{\circ}}$ | Iodine value | Sap. value | Unsap. matter Pet. ether extract |
|---|----------------------|--------------|------------|--|
| Specially processed and deodorised | 1.4599 | 66.6 | 214.0 | 0.44% |
| Egyptian Oil | 1.4585 | 57.2 | 213.5 | 0.30% |
| African Oil, same source as above | 1.4599 | 67.8 | 209.0 | 0.43% |

The Egyptian oil has the greater sale in this country and is supposed to be obtained from the liver and glands.—W. Lee, *Analyst*, 1935, 650.

A specimen of green turtle oil from *Chelonia japonica* Thunbery, from the Bonin islands, an orange-yellow liquid with a deposit at ordinary temperature. Very little colour was given with the antimony trichloride test; sp. gr. at 20°/4°, 0.9150; $n_{D_{20}^{\circ}}$, 1.4662; saponification value, 205.8; iodine value (Wijs), 64.1; acid value, 1.36; unsaponifiable matter, 0.52%. The fatty acids converted to methyl esters, fractionally distilled and the fractions examined for their component acids gave, as chief constituent, oleic acid, with myristic, palmitic and stearic acids also present together with a small proportion of the highly unsaturated acids C_{20} and C_{22} . The oil differs from most marine animal oils in the comparative lack of C_{20} and C_{22} acids.—M. Tsujimoto, *Perfum. essent. Oil Rec.*, 1937, 273.

Other figures are given for oil of green turtle by C. Hata (*Analyst*, 1939, 64, 610). Physical and chemical properties and vitamin content have been examined and published in *J. Amer. pharm. Ass.*, 1940, 437.

Oleum Maydis (U.S.P. XI). Sp. gr. at 25°, 0.914 to 0.921; saponification value, 188 to 193; iodine value, 112 to 128; unsaponifiable matter, not more than 2%.

The British Standard Specification for crude maize oil obtained from maize germ, *B.S.S. No. 651*—1936, does not provide for decomposed oil recovered after a fermentation process and known as "Fermentation Maize Oil." The specification includes requirements for colour, specific gravity, refractive index, iodine value, saponification value, acidity and unsaponifiable matter.

OLEUM RICINI

Oleum Ricini (B.P.). Sp. gr., 0.958 to 0.969; $n_{D_{40}^{\circ}}$, 1.4695 to 1.4730; acid value, not more than 4.0; saponification value, 177 to 187; iodine value, 82 to 90; α_D , not less than +3.5. Remains bright when kept at 0° for 3 hours. **Oleum Ricini, U.S.P. XII**, has a sp. gr. of 0.945 to 0.965 at 25°; saponification value, 179 to 185; iodine value, 83 to 88.

Microscopic Identification of Castor Oil. A small drop of the oil is mixed with an equal quantity of a saturated solution of potassium hydroxide in *n*-butyl alcohol. The preparation is examined at a magnification of 430; characteristic crystals are formed, for microphotograph of which see *Amer. J. Pharm.*, 1937, 67.

The **Optical Rotation** of commercial varieties of castor oil varies within wide limits; that of inferior qualities, obtained by extraction of the cake with carbon disulphide, is extremely high. It has been suggested that this is due to auto-esterification of ricinoleic acid, the rotatory power of these condensation products increasing with the number of molecules of the acid which combine.—M. Roy, *Quart. J. Pharm.*, 1933, 596.

The **Solubility** of castor oil in alcohol decreases with age. Failure of the oil to pass solubility tests in alcohol of less strength than 95% should not be considered proof of adulteration.—H. P. Trevithick and M. F. Lauro, *J. Soc. chem. Ind., Lond.*, 1929, 528.

Effect of Heating on Rotatory Power of Castor Oil. The B.P. '14 solubility test in petroleum ether is unsatisfactory and depends on the latter containing some aromatic hydrocarbon. When petroleum ether (b.p. 50°/60°) containing less than 0.2% of aromatic hydrocarbon was used for the B.P. '14 test a clear mixture was obtained at 15.5° which was turbid on the addition of 3 vols. of the petroleum ether and on warming only cleared at 26.9°. The addition of as much as 4% of benzene was necessary before the petroleum ether would give a clear solution under the B.P. conditions at 21°.—T. T. Cocking and S. K. Crews, *Quart. J. Pharm.*, 1929, 217.

The B.S.S. No. 650—1936 for castor oil (Firsts' Quality) does not apply to oil which is intended for medicinal use and is included in the B.P. It includes a "cold test" for stearine, and requirements regarding colour (not deeper than a colour equivalent to 2.2 yellow and 0.25 red Lovibond units), sp. gr. (0.958 to 0.969), refractive index at 20° (1.477 to 1.481), iodine value (82 to 90), saponification value (177 to 187), solubility in alcohol at 0°, acidity (not exceeding the equivalent of 2.0% of oleic acid), unsaponifiable matter (not more than 1%) and acetyl value (not below 144). The specification does not include standards for optical rotation or viscosity.

OLEUM SESAMI

Oleum Sesami (B.P.). Sp. gr., 0.921 to 0.924; $n_{D40^{\circ}}$, 1.4650 to 1.4665; acid value, not more than 4.0; saponification value, 188 to 193; iodine value, 103 to 112. Complies with tests for absence of cottonseed oil and of arachis oil. The test for absence of sesame oil in other oils consists in agitating 2 ml. of the oil with 1 ml. of a 1% w/v solution of sucrose in hydrochloric acid and standing for 5 minutes, when the acid layer should not appear pink. **Oleum Sesami, N.F. VII**, has a saponification value of 188 to 193; iodine value, 103 to 115; sp. gr. at 25°, 0.916 to 0.921.

The B.S.S. No. 656—1936 for sesame oil does not apply to medicinal oil included in the B.P. The specification includes the usual tests for other oils and requirements for specific gravity, refractive index, iodine value, saponification value, acidity and unsaponifiable matter.

Oleum Sojæ (B.P.C.). Sp. gr., 0.924 to 0.927; $n_{D40^{\circ}}$, 1.4675 to 1.4685; acid value, not more than 5; saponification value, 190 to 194; iodine value, 130 to 137; unsaponifiable matter, 0.7 to 1.5%.

The B.S.S. No. 653—1936 for crude soya bean oil includes requirements regarding colour, sp. gr. (0.924 to 0.928), $n_{D10^{\circ}}$ (1.473 to 1.477), iodine value (129 to 141), saponification value (not below 190), acidity (not more than the equivalent of 1.5% of oleic acid), and unsaponifiable matter (not more than 1.2%).

Detection of Linseed Oil. For pure soya bean oil, $\frac{I-126.19}{H}$ is greater than 11, where I = the iodine value and H is the insoluble bromine value determined as follows:—2 g. of oil which has been made neutral by shaking with 10% sodium hydroxide, and filtering, is dissolved in 40 ml. ether and 5 ml. glacial acetic acid, bromine 0.8 ml. is added drop by drop from a burette, and the mixture kept at 0° for 3 hours. The precipitate is filtered off in a tared glass crucible, washed with four 10 ml. portions of ether at 0° and dried at 100° till of constant weight. The percentage result = H . The value for H in an oil may fall from about 0.55 to 0.20 during the course of a year.—J. F. Carriere, *Analyst*, 1930, 64.

Detection of Soya Bean Oil in Nut and Olive Oils. Shake 10 ml. of oil and 1 ml. of nitric acid together, place in a water-bath for 15 minutes and then allow to cool. In the case of olive and nut oils the mixture solidifies completely, soya bean oil gives a viscous, reddish-brown mixture, the coloration of which is sufficient to enable the presence of 10% to be seen in either of the preceding oils. The iodine values of the three oils are, nut oil, 84 to 105; olive oil, 78 to 95; soya bean oil, 130 to 142.—A. Richard, *Ann. Falsif.*, 1928, 21, 579, per *Quart. J. Pharm.*, 1929, 103.

OLEUM THEOBROMATIS

Oleum Theobromatis (B.P.). M.p., 30° to 35°. n_{D40}^{20} , 1.4565 to 1.4575. Acid value, not more than 4.0. Saponification value, 188 to 195. Iodine value, 35 to 40. The *U.S.P. XII* specifies a refractive index at 40° of 1.4537 to 1.4578 and an iodine value of 35 to 40. (The m.p. and saponification value limits are the same as the B.P. '32.) Solidification point of the fatty acids, 45° to 50°.

Genuine cocoa-butter extracted from five varieties of cocoa had a "crystallisation temperature" of 20.0°; Borneo tallow has a "crystallisation temperature" of about 31.3° and the presence of the latter in cocoa-butter can be shown by means of a special apparatus devised for determining this factor.—S. A. Ashmore, *Analyst*, 1934, 515.

Extracted Cocoa Butter. A large amount of cocoa butter is made by extracting with benzene the waste products (shell and broken seeds) of cocoa and chocolate manufacturing. The characteristics of such cocoa butter are pale yellow tending to grey in colour; m.p., 28° to 30°; acid value, 1.5 to 2.5; iodine value, about 38; saponification value, 193; tests for foreign fats negative.—Bodinus, *Quart. J. Pharm.*, 1929, 438.

Distinction between Pressed and Extracted Cacao Butter. 2 g. of the butter is dissolved in 5 ml. of chloroform in a dry test-tube and is gently mixed with 5 ml. fuming hydrochloric acid (1.192, about 37%). Extracted cocoa shell butter gives a lower layer pale green at first and dark green after a minute. When heated to 50° for 2 minutes with 2 drops of concentrated nitric acid (1.42) it becomes reddish brown with a violet tinge. In the case of expressed butter the mixture remains colourless. This reaction detects about 20 to 25% of added extracted cocoa butter. No colour is given by ordinary or hardened coconut fat, palm kernel fat, hardened whale oil, vegetable hard butter ("Cocola" and "Kernel"), French vegetable fat ("Banka") or English hard butter ("Mikon"). If 5 drops of sulphuric acid (1.84) are used in place of the 5 ml. of hydrochloric acid, as above, the mixture becomes at once deep violet changing to brownish-violet after 2 minutes in a water-bath at 50° for extracted oil, whilst with mixtures of expressed and extracted oils the colour is pale brown in the cold, deep brownish violet at 50°. Expressed butter gives a colourless mixture cold and a reddish-yellow with violet tinge at 50°. About 10% of extracted butter is detectable.—Aufrecht, *Analyst*, 1929, 346.

Aufrecht's tests may sometimes give misleading results according to the nature of the manufacturing process and the amount of shell present. If 0.5 to 1 g. of the fat is melted in a test-tube and shaken with 3 ml. of glacial acetic acid, and when the acid layer has separated it is observed in filtered ultra-violet light, a bright green-yellow fluorescence is obtained from solvent extracted products while expressed oils give no colour. Molin's antipyrine test may be used by mixing 0.5 g. of butter, 2 ml. of 95% alcohol, 3 ml. of hydrochloric acid (1.19) and a few crystals of antipyrine, boiling and allowing to cool. The liquid layer develops a red colour. These reactions are not given by coconut oil or palm oil.—A. Castiglioni, *Analyst*, 1935, 257.

Examination in Ultra-violet Light. 0.1 g. is weighed into a thin-walled test tube and dissolved in 10 ml. of petroleum ether and examined in ultra-violet light. A non-fluorescent butter is almost certainly not solvent extracted. A strongly fluorescent sample is either solvent extracted or contains mineral oil. Mere traces of mineral oil such as may occur from factory waste give rise to strong fluorescence. With slight fluorescence no definite conclusion can be drawn.—W. T. Field, *Analyst*, 1930, 744.

Detection of Coconut and Palm Kernel Oils. These tests depend upon the complete insolubility of cacao butter soap in sodium chloride solution. Saponify about 2.5 g. of the cacao butter with alcoholic potash, drive off the alcohol and dissolve the soap in 50 ml. of hot water, allow to cool, add 50 ml. of saturated sodium chloride solution, agitate frequently during fifteen minutes and then filter. A further 50 ml. of saturated sodium chloride solution is added to the filtrate. The presence of coconut or palm-kernel oils is indicated by more than a slight opalescence.—F. Strube, *Yearb. Pharm.*, 1909, 20.

Saponify 5 g. of the sample with 10 ml. of alcoholic potash (25 g. of KOH in 200 ml. of alcohol), evaporate the alcohol, add 5 ml. of water and again evaporate, dissolve in 10 ml. of water and add with stirring 100 ml. of saturated sodium chloride solution, allow to stand 15 minutes, with occasional agitation and filter on a Buchner funnel. To 100 ml. of the filtrate add with stirring 100 ml. of saturated sodium chloride solution, allow to stand 15 minutes and again filter. Render the filtrate slightly acid with hydrochloric acid; a turbidity or milkiness indicates the presence of coconut or palm kernel fat in the sample.—W. F. Baughman, *Yearb. Pharm.*, 1926, 126.

Detection of Hardened Fats. A method depending on the fractional crystallisation of the lead salts of the fatty acids is as follows:—2.5 g. of fat is saponified with 1 ml. of 50% potash and 25 ml. of 95% alcohol. The soap solution is treated with 100 ml. of lead acetate solution (50 g. of lead acetate, 5 ml. of acetic acid 96%, and alcohol 80% to make 1 litre). The salts are completely dissolved by warming, 20 ml. of boiling water is added, and the mixture set aside overnight. Collect the precipitate in a glass Gooch crucible and wash with 50 ml. of alcohol 70%. The crucible is then fitted in an inverted position in an extractor, 3 ml. of acetic acid 96% is poured over the plate and the salts dissolved by extraction in 100 ml. of the lead acetate solution; after the addition of 15 ml. of hot water and agitation the mixture is set aside overnight. The lead salts are again collected, dissolved in 5 ml. of acetic acid and 10 ml. of alcohol 96% and then decomposed whilst warm with 5 ml. of nitric acid (1 : 2) in a flask filled to the neck and warmed so that the fatty acids separate as a clear layer. When cold the acid cake is removed, washed with cold water, dried in a steam oven, returned to the dried-out flask, dissolved in chloroform and used for the determination of the iodine value. The result is expressed in terms of *isooleic* acid in the original fat. One ml. of N/10 thiosulphate = 0.565% of *isooleic* acid. The presence of as little as 9.3% of hardened arachis oil in cacao butter can be detected.—J. Grossfeld, *Quart. J. Pharm.*, 1930, 643.

OPIUM

Opium (B.P.). Contains in its moist state as imported not less than 9.5% of morphine calculated as anhydrous. Assayed by the B.P. method: 8 g. mixed thoroughly in a mortar with 30 ml. of water and 2.0 g. of calcium hydroxide is transferred to a tared flask, with water to 90 g.; after shaking for 30 minutes, the mixture is filtered and 52 ml. of the filtrate (equivalent to 5 g. of the opium) shaken with 5 ml. of alcohol and 25 ml. of ether, 2.0 g. of ammonium chloride added, shaken for 5 minutes and occasionally during 30 minutes, the total time of shaking being 15 minutes, and stood overnight; the ethereal layer is decanted on to a plug of cotton wool in a funnel, the flask and contents and filter rinsed with 10 ml. of ether, and the filter with a further 5 ml. in small portions; the aqueous liquid is then poured through the filter, and the flask and filter washed with morphinated water till free from chloride; the crystals on the filter are washed back into the flask, boiled with excess N/10 sulphuric acid, and the cooled liquid titrated with N/10 sodium hydroxide to cochineal or methyl red, a correction of 0.052 being added.

Opium, *U.S.P. XII*, should yield not less than 9.5% of anhydrous morphine. It is assayed by a similar process on the water-soluble matter, finally treating the crude morphine on the filter with hot neutral methanol. The hot solution of morphine in methanol is cooled and excess of N/10 sulphuric acid is added. The solution is then diluted with distilled water and boiled carefully to remove the methanol, since the titration end-point to methyl red is not very delicate in its presence. The amounts of methanol specified in the *U.S.P. XI* were not always sufficient to dissolve all the morphine in the crude precipitate, and the *U.S.P. XII* uses a larger quantity. No correction for the solubility of morphine is allowed. The *U.S.P. XI* process gave results showing as much as 0.75 to 1.5% less morphine than the *U.S.P. X* method, and on the average for high testing opiums, about 1.5% less morphine than the *B.P.* method. The assay process of the *Fr. Cx.* 1937 is similar to the International process given below. The concentrated extract is also assayed for other alkaloids by extraction with ether-chloroform from sodium hydroxide liquid; morphine content 50% and other alkaloids 30%.

League of Nations' Process. A report of a Commission of Experts for the Standardisation of Methods for Determining the Morphine Content of Raw Opium described an assay process which was published, with some comments by Prof. L. van Itallie, in the *Bulletin de la Fédération Internationale Pharmaceutique*, 1933, 14, 98.

The experts' method has now been published by the Health Committee of the League of Nations and is preceded by a method of sampling, the practical utility of which has yet to be established.—*Bull. Hlth Org. L. o. N.*, 1938, 429.

The determination is carried out in three parts. (1) Determination of the loss of weight on drying at 103° to 105° (moisture). (2) Determination of the amount of extractive soluble in water in the presence of calcium hydroxide under the conditions of the process. (3) Determination of the morphine content.

Determination of the Loss in Weight on Drying (Moisture). Weigh 1 g. of opium (to within ± 5 mg.) in a weighing-bottle with a ground-in stopper; heat for two hours at 103° to 105° and weigh. Continue heating until the loss in weight after 1 hour in the oven is not more than 0.005 g. The loss in weight is calculated on 100 g. of the opium being analysed and in the following formula this percentage loss is denoted by the letter *F*. When dealing with soft opium the mass is diluted with a little water and dried in a thin layer.

Determination of the Extractive and of the Morphine. Triturate in a mortar 4 g. opium (weighed to within ± 5 mg.) with 1 g. of calcium hydroxide and 10 ml. of water so as to produce a homogeneous mixture. Dilute with another 10 ml. of water and set aside the mixture for 15 minutes, stirring frequently. Then by means of small quantities of water transfer the mixture to a small tared flask and add water until the contents of the flask weigh 45 g. (weighed to within 0.1 g.). Cork the bottle and shake vigorously and continuously for 30 minutes. Pour out the contents of the bottle on to a glass filtering funnel No. 3G3 of Schott and Gen, Jena, or on to a filtering funnel of similar pattern but having the same porosity and suitable dimensions. The liquid is at first allowed to flow freely, then the slightest possible suction is applied. Part of the filtrate is used to determine the extractive and part for the determination of the morphine.

A. DETERMINATION OF THE CONTENT OF EXTRACTIVE. Concentrate on a water-bath 3 g. of the filtrate (weighed to within ± 0.1 g.), then dry the remainder at 103° to 105° until the loss in weight after drying for one hour is not greater than 0.003 g. The weight of the remainder, in mg., is used for determining the extractive (*E*) given by 100 g. opium, according to the following formula:—
$$E = \frac{(1000 + F) M}{3 - M}$$
 where *M* denotes the weight in grammes of the residue from 3 g. of the filtrate and *F* the percentage of moisture in the opium.

B. DETERMINATION OF THE MORPHINE CONTENT. In a 50 ml. Erlenmeyer flask, or in some other suitable vessel, weigh 25 g. of filtrate (to within ± 0.1 g.) and add 2.5 ml. of alcohol (90%) and 12.5 ml. of ether. Close the flask, shake it to mix the liquids and add 1 g. of ammonium chloride. Shake well for 5 minutes, then frequently during 30 minutes. Set aside the mixture in the closed flask until the next day. Shake well to detach the precipitated morphine and pour the contents of the flask as completely as possible on to a filtering funnel No. 3G4 of Schott and Gen, Jena, or on to a filtering funnel of similar pattern, but having the same porosity and suitable dimensions. Avoid wetting the upper part of the funnel. Filter the liquid completely with the help of slight suction, then wash the flask with 3 ml. of ether; pour the latter on to the filtering funnel and without using suction wash it by inclining and shaking, then filter the ether completely by suction. The washing of the flask and the filtering funnel is repeated in the same way, each time with 3 ml. of water saturated with morphine, until the filtrate gives no reaction for chlorides. Heat the flask, in which there may still remain a little morphine, and the glass filtering funnel containing the greater part of the morphine, for 30 minutes at a temperature of 103° to 105° . After cooling, grease the upper and inner part of the filtering funnel to a depth of 0.5 cm. with soft paraffin; then fix it by means of a cork into a 300 cm. filtering flask. Warm 10 ml. of methyl alcohol in the flask (preferably with a reflux condenser because of the toxicity of the vapour of methyl alcohol) to dissolve the remaining crystals of morphine attached to it; pour the warm solution on to the filtering funnel without applying suction, dissolve the greater part of the morphine by shaking, and filter the solution using suction. This operation is repeated twice, using each time 10 ml. of methyl alcohol. Then, by means of a small wash-bottle rinse all the deposits of morphine which may have formed on the filtering funnel and on the lower tube with 10 ml. of methyl alcohol; pour this alcohol into the filtering flask. The impurities in the morphine will thus remain on the plate of the filter. Verify whether the filtrate is quite clear; should a little morphine be precipitated dissolve it by warming slightly. Add to the clear liquid 5 to 10 drops of methyl red and titrate with N/10 hydrochloric acid or N/10 sulphuric acid to a faint orange. Dilute the liquid with 120 ml. of freshly boiled and cooled water, which changes the colour of the solution to yellow; and complete the titration by adding N/10 acid until the liquid begins to turn red.

The morphine content is calculated according to the following formula:

$$(a) \text{ in \% of anhydrous opium } \frac{(1000 + E + F)(A + 1) \cdot 0.114}{100 - F}$$

$$(b) \text{ in \% of original opium } \frac{(1000 + E + F)(A + 1) \cdot 0.114}{100}$$

E = percentage yield of extractive in the presence of calcium hydroxide, calculated on the opium.

F = percentage of moisture in the opium.

A = ml. of N/10 acid used in the titration.

This formula allows for a correction of 1 ml. of N/10 acid (equivalent to 0.0285 mg.) for the morphine remaining in solution.

Some Defects in the International Process. The process is undoubtedly superior to many published methods, and particularly to the official methods of most foreign pharmacopœias. It is, however, much more complicated and troublesome to perform than the method of the British Pharmacopœia and it is extremely doubtful whether it is superior or even equal to the latter method as regards accuracy.

Its principal disadvantages are:

(1) The very small weight of opium used for the test.
 (2) The unnecessarily involved practical details, some of which could quite well have been dispensed with without appreciably diminishing the accuracy of the results.

(3) The decidedly clumsy manipulation, such as the weighing of all liquids, the method adopted for the initial filtration and the directions for the collection, washing and solution of the morphine. Some of these defects cannot fail to cause very appreciable errors.

If the process is performed exactly as described, it appears very improbable that close agreement between different analysts using the method will occur. In order to produce a really accurate method capable of giving reasonably consistent

results in different hands very considerable modifications would be needed, some of which might very well be in the direction of simplification.

Observations on the opium assay.—J. Rosin and C. J. Williams, *J. Amer. pharm. Ass.*, 1935, 1953.

Proposed Alternative Assay Process. The following method represents an attempt to eliminate sources of error in previously published methods due to incomplete extraction of the opium, inaccurate calculations of the aliquot proportions, incomplete precipitation of the morphine and its contamination with other substances.

3 g. of finely powdered sample is heated for 10 minutes on a boiling water-bath with 50 ml. of N/20 sulphuric acid, stirring to produce a uniform suspension, and 8 g. of anhydrous sodium sulphate is dissolved in the mixture which is then cooled and allowed to stand for 30 minutes. The mixture is filtered through filter paper supported on a 3G3 glass filter, and the filter washed with 3 ml. of a saturated solution of sodium sulphate in N/20 acid. The filtrate is shaken vigorously with 5 ml. of 4N sodium hydroxide. The residue on the filter is heated with 30 ml. of N/20 sulphuric acid for 5 minutes, treated with 4.5 g. of anhydrous sulphate, cooled, filtered, and the filter washed as before. If the opium is rich in morphine, three extractions should be carried out using 45, 20 and 15 ml. of acid respectively with corresponding amounts of sodium sulphate. The mixed filtrates are diluted to 90 ml., shaken well and allowed to stand for 30 minutes and then filtered through a thick folded filter paper. The filtrate is shaken with 80 ml. of benzene, and after separation, 75 ml. of the aqueous extract (= 2.5 g. of sample) is pipetted off and shaken vigorously for 1 minute with 2 g. of sodium bicarbonate and 75 ml. of a warm mixture of chloroform and alcohol (3:2). The chloroformic extract is run off into a second separator and treated with 25 ml. of pure chloroform and 2 ml. of water, and the flask rotated without shaking and the aqueous layer rejected. The extraction is repeated with 30 and 15 ml. of warm chloroform-alcohol mixture and the chloroformic extracts run off into the second separator. The mixed chloroformic extracts are allowed to stand 30 minutes and then filtered through cotton wool which has been covered with a little anhydrous sodium sulphate, the filter being rinsed with two quantities, each of 5 ml., of chloroform. The chloroform is evaporated and the residue is warmed on a water-bath with 1 ml. of alcohol and 25 ml. of benzene until almost completely dissolved. 20 ml. of N/2 sodium hydroxide is added, followed by 1.5 g. of ammonium sulphate, and the mixture is shaken vigorously for 2 minutes and then, after 12 hours, filtered through a 3G3 filter, the flask and filter being rinsed with 2 ml. of benzene, then three times with 5 ml. of water saturated with morphine, and finally with 3 ml. of ether. The morphine in the flask is dissolved in 15 ml. of N/10 hydrochloric acid, warmed on a water-bath, and the solution transferred quantitatively to the filter, any morphine still remaining being dissolved by the further addition of 5 to 10 ml. of the acid. Flask and filter are thoroughly washed with recently boiled and cooled water. The solution is titrated to the yellow colour of methyl red with N/10 alkali and then with N/10 acid until the red colour begins to return. To the volume of acid used by the alkaloid 0.4 ml. is added to correct for the morphine remaining in the mother liquor. 1 ml. of N/10 acid corresponds to 0.0285 g. of anhydrous morphine.—E. Knaff-Lenz, *Pharm. Monatschef.*, 1937, 17.

Eder and Wackerlin's Method (*Quart. J. Pharm.*, 1937, 680). Carefully triturate 1 g. of opium with 1 ml. of water in a 30 ml. mortar, having a roughened inner surface, until homogeneous. Mix with 1 ml. of water and 0.4 g. of calcium hydroxide and then gradually add 8 ml. of water. Filter directly into a 150 ml. separating funnel through a 3G3 or 3G4 sintered glass filter using slight suction. Rinse the pestle and mortar with 7 ml. of water, pour on to the filter with the suction discontinued, rub the opium to a smooth paste, filter, and repeat the procedure five times. To the filtrate add 0.3 g. of ammonium chloride and shake for 1 minute with 60 ml. of chloroform-isopropyl alcohol mixture (3+1). Allow to separate and then stand for 10 minutes, filter through a double filter wetted with the solvent mixture into a 250 ml. separating funnel. Repeat the extraction twice using 40 and 30 ml. of solvent mixture, and finally wash the filter with a further 15 ml. Shake the mixed filtrates with 20 ml. of N/10 sodium hydroxide for 1 minute, draw off the chloroform-isopropyl alcohol layer and pour off the alkaline layer through the neck of the funnel, rinsing the neck with a few drops of water. Return the chloroform-isopropyl alcohol solution to the funnel and repeat the procedure twice using 15 and 10 ml. of

N/10 sodium hydroxide, finally washing the funnel with 3 ml. of water and adding to the alkaline liquid. To the latter is added 0.5 g. of ammonium sulphate and the liquid extracted three times with solvent mixture using quantities of 60, 40 and 30 ml., filtering each time and using 15 ml. of solvent mixture to wash the filter. Evaporate the solution to 10 ml., transfer to a 50 ml. stoppered flask using three quantities, each of 5 ml., for rinsing, and evaporate the solvent at 80° in a current of air. Cool the residue, add 1 ml. of alcohol 95%, 10 ml. of N/10 sodium hydroxide and 5 ml. of ether, stopper, and shake until dissolved. Add 0.4 g. of ammonium chloride and shake until the morphine begins to precipitate and for 5 minutes longer. Allow to stand overnight, noting the temperature. Shake, cool in cold water, filter through a sintered glass funnel, washing flask and funnel successively with 2 ml. of ether and then four quantities each of 2 ml. of morphine-saturated water. Dissolve the morphine in 15 ml. of methyl alcohol, added in 3 ml. portions and washing the lower part of the funnel with the last 3 ml. Titrate to methyl red with N/10 acid, add 45 ml. of water and complete the titration. Deduct any acid used in a blank test on the methyl alcohol and add to the weight of morphine thus determined a correction depending on the temperature at which the morphine stood overnight. At 10° the correction is 0.0053 g., at 20° 0.0062 g., and at 30° 0.0080 g. Two variants of this method are also described.

The method is modified to remove substances which prevent the precipitation of morphine. A shorter variation of this improved method is given. The extraction of the opium is modified by triturating the paste, prepared from 5 g. of the drug and 5 ml. of water, with a further 5 ml. of water and 3 g. of manganese sulphate prior to the addition of the calcium hydroxide. In the new method 3 g. of calcium hydroxide are used. 50 ml. of the extract so prepared are washed with 60 ml. of a mixture of equal volumes of benzene and carbon tetrachloride, 0.4 g. of ammonium chloride is added and the solution shaken with 60 ml. of a mixture of 3 volumes of chloroform and 1 volume of isopropyl alcohol for one minute. After separation the chloroform-isopropyl alcohol layer is filtered through an adsorption filter, consisting of a tube 20 cm. long and 17 mm. internal diameter, which is packed with a plug of cotton wool moistened with chloroform-isopropyl alcohol, 5 g. of alumina (washed into the tube with chloroform-isopropyl alcohol) and finally a layer of filter paper. The extraction is repeated with 40 and 30 ml. portions of chloroform-isopropyl alcohol and the extracts also passed through the adsorption filter. The latter is then washed with three 10 ml. portions of chloroform-isopropyl alcohol. The filtrate is evaporated to 10 ml., placed in a 50 ml. flask and the solvents completely removed by heating to 75°. The crude morphine is then purified and titrated as described originally. According to the temperature at which the morphine is allowed to stand, the following correction is added: 10°, 0.0064 g.; 20°, 0.0073 g.; 30°, 0.0091 g. of morphine. Finally, methods are given for the homogenisation of opium samples and for the determination of water in them. —R. Eder and E. Wäckerlin, *Pharm. Acta Helvet.*, 1940, 15, 227.

Varieties. Turkey opium is produced in Asiatic Turkey and occurs in rounded, conical, irregular or flattened masses usually enveloped in poppy leaves, and sometimes more or less covered with the winged fruits of a species of *Rumex*. The weight of the cakes varies from about 1 oz. to several pounds, the majority of the pieces varying from about 1 lb. to 4 lb. Turkey opium includes the varieties, "Soft Shipping" opium and "Druggists" opium. It is now exported in cases containing usually 40 pieces of more uniform consistency and shape, each piece weighing about 4 lb. or 4 kilos. European opium is produced chiefly in Bulgaria, Greece and Yugoslavia; it resembles the "Soft Shipping" variety of Turkey opium in its general characters. Yugoslavian monopoly opium occurs in fairly uniform flattish and elongated oval masses, each weighing about $\frac{3}{4}$ or 1 lb. Persian opium occurs in brick-shaped masses weighing about 1 lb., usually wrapped in red paper and tied with red string. It formerly contained varying proportions of certain native gums added during manufacture to obtain a product suitable for moulding, but this addition is now prohibited. Indian medicinal opium occurs in square blocks weighing about 2 lb. and is wrapped in white paper. Bulgarian, Russian and Syrian opiums are occasionally exported.

Constituents. Opium contains morphine in proportions varying from 5 to 21% of the dried opium. The morphine exists in combination with meconic and sulphuric acids in the form of salts readily soluble in water. The "Soft Shipping" variety of Turkey opium contains about 15 to 18% of morphine,

while "Druggists" opium of good quality contains about 12 to 16%. Dried European opium contains from about 15 to 21% or occasionally more. Persian opium contains about 10 to 12% and occasionally as much as 13.5%. Undried Indian medicinal opium has varied considerably at different times, sometimes containing as little as 7%, and sometimes as much as 12%. Narcotine ranges from 1.5 to 12.5%. Codeine exists to the extent of 0.3 to 4%, Indian opium containing the highest proportion and Turkey opium the lowest. The remaining alkaloids constitute about 1% of the drug. They include thebaine, narceine, papaverine, meconidine, codamine, laudanine, laudanoline, neopine, lanthopine, protopine, cryptopine, rhœadine, oxynarcotine, pseudo-morphine, gnoscopine, xanthaline (papaveraldine), tritopine, hydrocotarnine, porphyroxine (in Indian opium) and possibly others. Meconin, meconoidin and opionin are indifferent substances, present in small proportions only. Other constituents are mucilage, sugar, wax and rubber, together with salts of calcium, magnesium and potassium.

Determination of morphine, narceine, narcotine, papaverine, codeine and thebaine in opium.—B. Kljotschkina, *Arch. Pharm., Berl.*, 1933, 271, 558, per *Quart. J. Pharm.*, 1934, 119.

Opium Pulveratum (B.P.). Adjusted with lactose to contain from 9.5 to 10.5% of morphine, calculated as anhydrous. Opium Pulveratum, *U.S.P. XII*, yields from 10 to 10.5% of anhydrous morphine.

Extractum Opii Siccum (B.P.). Contains 19 to 21% of morphine, calculated as anhydrous. Assayed by trituration of 4 g. with 5 ml. of water and then 20 ml. of water and 2 g. of calcium hydroxide, finally adjusting with water to 86 g. The assay is then completed as for Opium, taking 52 ml. of the filtered liquid representing 2.5 g. of the original extract.

Tinctura Opii (B.P.). Contains 0.95 to 1.05% *w/v* of morphine, calculated as anhydrous. Assayed by evaporation of 80 ml., trituration with 5 ml. of water, addition of 20 ml. of water and 2 g. calcium hydroxide, followed by addition of water to 86 g., then proceeding as for opium, taking 52 ml. of the filtrate equivalent to 50 ml. of the tincture. Alcohol content, 41 to 46% *v/v*. Tinctura Opii, *U.S.P. XII*, contains 0.95 to 1.05% *w/v* of anhydrous morphine, and has an alcohol content of 17 to 19% *v/v*.

Tinctura Opii Camphorata (B.P.). Contains 0.045 to 0.055% *w/v* of morphine, calculated as anhydrous. Assayed by extraction of the residue, after evaporation, with calcium hydroxide solution, cleaning the solution with ether, addition of ammonium sulphate and extraction with twice the volume of chloroform-alcohol mixture (1 : 1) followed by extraction with chloroform-alcohol mixture (1 : $\frac{1}{2}$); after evaporation of the solvent, the residue is dissolved in N/1 hydrochloric acid and diluted with water to N/10 solution. The brownish colour produced by a 20 ml. portion of the solution on addition of 8 ml. of 1% sodium nitrite solution and 12 ml. of dilute ammonia solution is matched against a standard solution of morphine in N/10 hydrochloric acid. Alcohol content 56 to 60% *v/v*. Tinctura Opii Camphorata, *U.S.P. XII*, yields 0.035 to 0.045% *w/v* of anhydrous morphine; assayed by evaporation with 1/50 volume of N/1 sulphuric acid to low bulk, making just ammoniacal, adding sodium chloride and extraction with alcohol-chloroform (15 : 85); the morphine is subsequently

transferred to 2.5% sodium hydroxide solution saturated with salt, cleaned in hydrochloric acid, salt solution with chloroform, made ammoniacal and extracted with the alcohol-chloroform, evaporated to low bulk, and titrated in alcohol with N/50 sulphuric acid to methyl red indicator.

Tinctura Opii Camphorata Concentrata (*B.P. Add. V*). After dilution and evaporation, it is assayed by the *B.P.* process for Tinctura Opii Camphorata. Contains 0.36 to 0.44% *w/v* of anhydrous morphine.

The Pharmacopœial method for the determination of small amounts of morphine as in camphorated tincture of opium gives high results when applied to other substances owing to the presence of non-morphine chromogenic substances. A quantity of extractive equal to the test solution should be added to the standard before making the comparison. The colorimetric method is then applicable to other preparations containing opium as follows:—

Aromatic Powder of Chalk with Opium. Mix intimately 4 g. of sample with 0.5 g. of slaked lime in a mortar, add water to make a paste, and then transfer quantitatively to a 100 ml. flask with water until about 90 ml. have been used. Shake the mixture occasionally during 30 minutes, make up to volume and filter. Add 0.15 g. of ammonium sulphate to 25 ml. of the filtrate, extract three times with ether, wash the ether with 5 ml. of water and reject the solvent. Extract the aqueous liquid as in the official method for camphorated tincture of opium and make the residue, obtained after evaporation of solvent, up to 25 ml. with N/1 hydrochloric acid before matching.

Powder of Ipecacuanha and Opium. Mix intimately 1 g. of sample with 0.5 g. of slaked lime in a glass mortar. Add water gradually and transfer quantitatively to a 100 ml. graduated flask. Shake the mixture (approximately 90 ml.) frequently during 30 minutes; make up to 100 ml., shake and filter. Extract 25 ml. of filtrate first with ether and then, after adding ammonium sulphate, with alcohol and chloroform as in the Pharmacopœial assay of camphorated tincture of opium. Dissolve the residue in 25 ml. of N/1 hydrochloric acid. Match against standard morphine solution as usual, a convenient amount being 5 ml. of extract and 5 ml. of 0.01% anhydrous morphine solution.

Gall and Opium Ointment. Extract 3.5 to 4 g. of ointment with light petroleum in a Soxhlet apparatus until the residue is free from fat (3 hours). Dry the residue and continue the assay on the total dry powder as given for Dover's powder. Calculate the anhydrous morphine to the original ointment.

Tincture of Chloroform and Morphine. To 10 ml. of tincture in a separator add 5 ml. of water followed by 0.5 ml. of strong solution of ammonia, 15 ml. of alcohol and 15 ml. of chloroform. After shaking and separating, repeat the extraction twice with 8 ml. of alcohol and 15 ml. of chloroform, washing the solvent each time with the same portion of 15 ml. of a 1 : 2 mixture of alcohol and water. After evaporating the solvent, dissolve the residue in 75 ml. of N/1 hydrochloric acid and match 2 ml. against a standard morphine solution.—D. C. Garratt, *Quart. J. Pharm.*, 1937, 466.

OPIUM ALKALOIDS AND DERIVATIVES

Æthylmorphinæ Hydrochloridum (*B.P.C.*).

$C_{19}H_{23}O_3N \cdot HCl \cdot 2H_2O = 385.7$. Loss at 100° , not more than 10%. Ash, not more than 0.1%. A morphine limit equivalent to 0.1% of anhydrous morphine is included by matching against a standard solution the colour produced by 5 ml. of a 2% solution in N/10 hydrochloric acid on the addition of 2 ml. of 1% sodium nitrite solution and 3 ml. of dilute ammonia. **Æthylmorphinæ Hydrochloridum**, *U.S.P. XII*, loses not more than 10% at 100° .

Apomorphinæ Hydrochloridum (B.P.).

$C_{17}H_{17}O_2N \cdot HCl \cdot \frac{1}{2}H_2O = 312.6$. Loss at 100° , not more than 5%. Ash, not more than 0.1%. 0.1 g. shaken with 5 ml. of ether, should produce not more than a faint red colour (due to decomposition products). The *U.S.P. XII* salt complies with the test for decomposition products and is rejected if it produces immediately an emerald-green colour when shaken with 100 parts of water.

Tabellæ Apomorphinæ Hydrochloridi (N.F. VII). Contain 91 to 107% of the labelled amount of apomorphine hydrochloride, including all tolerances. The tablets must be rejected if an emerald green colour is produced immediately when they are dissolved in water in the proportion yielding a 1% solution of apomorphine hydrochloride. Assayed by dissolving a weighed quantity of powdered tablets in water, adding sodium bicarbonate, extracting with ether, washing the ether with water and extracting the aqueous washings with a further portion of ether. The combined ether extracts are extracted with N/20 sulphuric acid and the excess acid titrated with N/50 sodium hydroxide using methyl red indicator.

An official method for the determination of apomorphine in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 587)*. The apomorphine, extracted with peroxide-free ether from a solution made alkaline with sodium bicarbonate, is dissolved in excess standard sulphuric acid and back-titrated with standard sodium hydroxide solution, using methyl red as indicator.

Codeina (B.P.). $C_{18}H_{21}O_3N \cdot H_2O = 317.2$. M.p. of the dried substance, 155° to 156° . Loss at 100° , not more than 6%. Ash, not more than 0.1%. 5 ml. of the 2% w/v solution in N/10 hydrochloric acid, with 2 ml. of 1% sodium nitrite solution and 3 ml. of dilute ammonia solution, produces a yellow colour not deeper than 5 ml. of 0.002% w/v solution of anhydrous morphine in N/10 hydrochloric acid, similarly treated. Codeina, *U.S.P. XII*, loses not more than 6% at 80° ; a test for morphine with ferric chloride and potassium ferricyanide is included; 0.01 g. complies with the test for carbonisable substances.

An official method for the determination of codeine in tablets is described in *Methods of Analysis (A.O.A.C., 1940, 587)*. A solution of the sample in dilute hydrochloric acid is made slightly alkaline with sodium bicarbonate, and extracted with chloroform. The chloroform is removed, the residue dissolved in methyl alcohol and either titrated directly with standard sulphuric acid, or dissolved in excess standard sulphuric acid and back titrated with standard sodium hydroxide, using methyl red as indicator.

Codeinæ Phosphas (B.P.). $C_{18}H_{21}O_3N \cdot H_3PO_4 \cdot H_2O = 415.2$. Loss at 100° , 4 to 7%. Complies with the limit test for morphine. The *U.S.P. XII* substance is the salt with $1\frac{1}{2}$ molecules of water of crystallisation and contains not less than 70% of anhydrous codeine, by extraction from solution with sodium hydroxide by chloroform and titration with N/10 sulphuric acid to methyl red.

Tabellæ Codeinæ Phosphatis (U.S.P. XII). Contain 93 to 107% of the labelled amount of $C_{18}H_{21}O_3N \cdot H_3PO_4 \cdot 1\frac{1}{2}H_2O$, including all tolerances. Assayed by macerating overnight a weighed quantity of powdered tablets with water and N/2 sulphuric acid, filtering and extracting with chloroform the codeine from an aliquot of the filtrate, made alkaline with ammonia solution. After removal of nearly all the chloroform an excess of N/50 sulphuric acid is added, the remainder of the chloroform removed, the solution cooled and titrated with N/50 sodium hydroxide using methyl red indicator.

Codeinæ Sulfas (U.S.P. XII). $(C_{18}H_{21}O_3N)_2 \cdot H_2SO_4 \cdot 5H_2O = 786.5$. Loss at 100° , not more than 12%. Complies with tests for acidity, morphine and carbonisable impurities.

Tabellæ Codeinæ Sulfatis (*U.S.P. XII*). Contain 93 to 107% of the labelled amount of $(C_{18}H_{21}O_2N)_2 \cdot H_2SO_4 \cdot 5H_2O$, including all tolerances. Assayed by the process described for codeine phosphate tablets.

Dihydromorphinoni Hydrochloridum (*U.S.P. XII*). Loss at 100°, not more than 1.5%. Complies with tests for acidity and absence of ammonium salts and codeine.

Tabellæ Dihydromorphinoni Hydrochloridi (*U.S.P. XII*). Contain 90 to 110% of the labelled amount of $C_{17}H_{19}O_3N \cdot HCl$, including all tolerances. Assayed by extraction with chloroform from a weighed quantity of powdered tablets dissolved in saturated sodium bicarbonate solution. After filtration of the chloroform extracts, the chloroform is removed and the alkaloid determined by addition of excess N/50 sulphuric acid and back titration with N/50 sodium hydroxide, using methyl red indicator.

Diamorphinæ Hydrochloridum (*B.P.*).

$C_{21}H_{25}O_5N \cdot HCl \cdot H_2O = 423.7$. Ash, not more than 0.1%. A morphine limit, as indicated by the colour produced in N/10 hydrochloric acid solution with sodium nitrite and ammonia, is included and is equivalent to 1.5%.

An official method for the determination of diamorphine in tablets is described in *Methods of Analysis* (*A.O.A.C.*, 1940, 587). The diamorphine, extracted with chloroform from ammoniacal solution, is dissolved in methyl alcohol and either titrated directly with standard sulphuric acid, or dissolved in excess standard sulphuric acid and back-titrated with standard sodium hydroxide, using methyl red as indicator.

Determination of Diamorphine in Mixture with Procaine. Details are given of a method which depends on hydrolysing the mixture in acid solution, adding excess alcohol and shaking with chloroform and alcohol when only morphine and diethylaminoethanol are extracted and *p*-aminobenzoic acid remains in solution. The former may be separated by the solubility of morphine in lime water.—*Amer. J. Pharm.*, 1938, 362.

Morphina (*B.P.C.*). $C_{17}H_{19}O_3N \cdot H_2O = 303.2$. Loss at 110°, not more than 7%. Ash, not more than 0.1%. Complies with the limit test for other alkaloids in *Morphinæ Hydrochloridum*, using three-quarters the quantity of substance.

Identification. A description and discussion of 21 classified chemical tests for morphine.—*C. C. Fulton, Amer. J. Pharm.*, 1937, 219.

Colorimetric Determination. The reagent is prepared as follows:—Molybdic acid anhydride 14.4 g. is dissolved in 100 ml. of warm N/1 sodium hydroxide and sodium silicate solution is added to bring the SiO_2 content to 0.7 g. 10% hydrochloric acid is then added with stirring until the solution becomes green, and then water to 900 ml. The mixture is placed on a boiling water-bath which is allowed to cool slowly, precipitated silica is filtered off after 24 hours and the volume made up to 1 litre. To 10 ml. of the solution of the sample in 1% hydrochloric acid (containing 0.2 to 10 mg. of morphine) is added 2 ml. of the reagent followed by 5 ml. of 5% ammonium hydroxide solution, and the mixture is diluted to 25 ml. The blue colour produced is matched against that produced by treating similarly a standard solution of morphine in 1% hydrochloric acid. The colour should be compared after standing for 15 to 20 minutes. Reducing agents other than morphine must be removed. Narcotine, papaverine and narceine give only a very faint colour; codeine, thebaine and meconic acid give no reaction although the first two discharge the yellow colour of the reagent.—*C. G. Van Arkel, Pharm. Weekbl.*, 1937, 134.

Determination with 1:2:4-Chlorodinitrobenzene. The following method, a modification of that of Mannich, based on the precipitation of morphine as the 2:4-dinitrophenyl ether, gives accurate results. Dissolve a weighed quantity of morphine salt in alcohol 30% to form a solution not stronger than 0.1% w/v. To 100 ml. of the solution add 10 ml. of strong ammonia solution and 5 ml. of 2% solution of 1:2:4-chlorodinitrobenzene in alcohol 95%. Allow to stand 18 hours, filter through a tared Gooch crucible,

wash with alcohol 30% and finally with ether, dry at 100° and weigh. 1 g. of ppt. is equivalent to 0.632 g. of anhydrous morphine. Insoluble dinitrophenyl ethers are given by other phenolic alkaloids and the method is unsatisfactory for the determination of morphine in opium.—J. R. Nicholls, *Analyst*, 1937, 440.

An official method for the determination of morphine in tablets is described in *Methods of Analysis* (A.O.A.C., 1940, 588). The sample is moistened with water and dissolved in an alkaline salt solution (3% sodium hydroxide in saturated sodium chloride solution). The solution is acidified with hydrochloric acid, and alcohol and a slight excess of ammonia added. The morphine extracted from this solution with chloroform-alcohol (9:1) is dissolved in methyl alcohol, and either titrated directly with standard acid, or dissolved in excess standard acid and back-titrated with standard sodium hydroxide solution. If other alkaloids may be present the initial solution in alkaline salt solution is first extracted with chloroform to remove them. An official method for the determination of morphine in syrups is also described (*ibid.*, 589).

Quantitative methods for the determination of morphine, codeine and diamorphine in tablets are also described.

A colorimetric method for the determination of morphine in hypodermic tablets and injections is described. The method depends upon a modification of Radulescu's colour reaction and tables are given correlating the value of the yellow component of the colour obtained to the morphine content. Details are also given for the determination of diamorphine which may be estimated by the same method after preliminary hydrolysis by refluxing with dilute hydrochloric acid.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 239.

Spectrum lines characteristic for morphine are obtainable with 1/200 grain.—J. J. Dobbie, *Lancet*, i/1913, 1399.

Bromophenol blue recommended as indicator for titration of morphine. A 1% solution of morphine hydrochloride has a pH of 3.65.—N. Evers, *Yearb. Pharm.*, 1921, 325.

Morphine and other alkaloids in animal excreta. Detection in organs, urine, etc.—*Yearb. Pharm.*, 1922, 12.

The fate of morphine in the animal body, with a method of estimation in body fluids and tissues.—*J. Pharmacol.*, June, 1927, 177.

Distinction from Oxydimorphine. Alkaloid dissolved in a 4% alcoholic solution of *p*-dimethylaminobenzaldehyde and solution warmed on a water-bath. Morphine gives a currant-red and oxydimorphine a green colour.—M. M. Pesetz, *J. Pharm. Chim., Paris*, 1938, 27, 255.

Extraction of Alkaloids from Viscera. The following is a summary of the method recommended.—Freeze the material, mince into a tared casserole while still frozen, add one half its weight of water and warm until homogeneous. Add 50 g. of ammonium sulphate and 2 ml. of glacial acetic acid for every 100 g. of minced material and warm to about 65° until coagulated. Filter in a Buchner funnel, washing the residue with water. If quinine is present, extract the residue with successive portions of water acidified with acetic acid 1%, using 1 to 1½ litres. The washings are collected separately, washed with ether to remove fat and saturate the liquid, rendered alkaline with ammonia and extracted 5 times with 75 ml. portions of ether. The ether is extracted with successive portions of dilute sulphuric acid, the alkaloid transferred to chloroform, and the crude quinine purified by dissolving in ethyl acetate, precipitating as the tartrate, dissolving the latter in water and extracting the base with chloroform after addition of ammonia.

If morphine is present the residue on the filter is extracted with hot saturated ammonium sulphate solution containing 1% of acetic acid until 1½ to 2 litres of filtrate has been collected. The latter is defatted with light petroleum, the aqueous layer rendered ammoniacal, and 100 to 150 ml. of alcohol added carefully to form a small upper layer. The morphine is then extracted with five 100 ml. portions of a chloroform-alcohol mixture (1:1). The extracts are washed twice with small quantities of water and then with three portions of 5% sodium hydroxide, the aqueous and alkaline extracts being acidified, rendered ammoniacal, and extracted with the chloroform-alcohol mixture. The solvent is evaporated and the residue extracted with hot ethyl acetate. The solution is evaporated to dryness, and the residue dissolved in alcohol 30%, and determined by Mannich's method.—C. G. Daubney and L. C. Nickolls, *Analyst*, 1937, 351.

All the acyl compounds of morphine, e.g., diacetylmorphine and benzoylmorphine, are readily decomposed and morphine recovered from them, whereas

the alkyl derivatives, such as codeine and benzylmorphine, are intimate compounds from which the morphine cannot be recovered. The former are strong narcotics like morphine, and the latter only weak narcotics.—D. B. Dott, *Pharm. J.*, ii/1928, 250.

Morphinæ Acetas (B.P.C.). $C_{17}H_{19}O_3N, C_2H_4O_2, 3H_2O = 399.2$. Ash, not more than 0.1%. Complies with the limit test for other alkaloids.

Morphinæ Hydrochloridum (B.P.). $C_{17}H_{19}O_3N.HCl, 3H_2O = 375.7$. Loss at 120° , not more than 12.5% and the dried material is not more than faintly yellow in colour. Ash, not more than 0.1%. Limit of other alkaloids extracted with chloroform from sodium hydroxide solution, not more than 1.5%. Morphinæ Hydrochloridum, *N.F. VII*, should lose not more than 15% at 100° . A test for apomorphine is described; complies with tests for free acid, ammonium salts, meconate, and foreign alkaloids.

GREGORY'S SALT. An impure morphine hydrochloride, being a mixture of double salt of morphine hydrochloride and codeine hydrochloride occurring in the manufacture of morphine.

Assay of Morphine in Morphine Salts. The following process for the assay is recommended by the Sub-Committee on Alkaloidal Assays of the Committee on Pharmaceutical Chemistry:—Transfer about 0.5 g., accurately weighed, to a separator, add 15 ml. of water, 5 ml. of N/1 sodium hydroxide and 10 ml. of chloroform. Shake, allow to separate, and remove the chloroform to another separator. Repeat the extraction with two further quantities each of 10 ml. of chloroform. Wash the mixed chloroform solutions with 10 ml. of N/10 sodium hydroxide, reserve the chloroform, and add the alkaline solution to the first alkaline liquid. Add 20 ml. of alcohol (90%), 40 ml. of a mixture of three volumes of chloroform and one volume of alcohol (90%), and 1 g. of ammonium sulphate. Shake well, allow to separate, and remove the chloroform solution. Repeat the extraction with successive quantities of 30, 20, 20 and 20 ml. of the chloroform-alcohol mixture. Wash each chloroform solution successively with two quantities, each of 5 ml., of water, avoiding vigorous shaking. Filter the chloroform solutions through a plug of cotton-wool, previously moistened with chloroform. Remove the solvent. Add 20 ml. of N/10 sulphuric acid, boil, cool, and titrate the excess of acid with N/10 sodium hydroxide using tincture of cochineal or solution of methyl red as indicator. Each ml. of N/10 sulphuric acid is equivalent to 0.02852 g. of anhydrous morphine. —(*British Pharmacopœia Commission Report*, No. 12, May 1939.) *This method has been included in B.P. Add. IV for the assay of morphine in morphine sulphate.*

Liquor Morphinæ Hydrochloridi (B.P.). Contains 0.95 to 1.05% w/v of morphine hydrochloride. Assayed by extraction from the solution to which alcohol and sodium bicarbonate have been added with chloroform-alcohol (3 : 1), finally drying at 115° and weighing. Alcohol content, 21 to 24% v/v.

Assay. The following process for the assay is recommended by the Sub-Committee on Alkaloidal Assays of the Committee on Pharmaceutical Chemistry:—Transfer 25 ml. to a separator, add 7.5 ml. of alcohol (90%) and 0.5 g. of sodium bicarbonate, and extract the alkaloid by shaking with successive quantities of 40, 30, 20 and 20 ml. of a mixture of three volumes of chloroform and one volume of alcohol (90%). Wash each chloroform solution with the same 5 ml. of water, contained in a second separator. Mix the chloroform solutions, remove the solvent; add 10 ml. of N/10 sulphuric acid, boil, cool, and titrate the excess of acid with N/10 sodium hydroxide, using tincture of cochineal or solution of methyl red as indicator. Each ml. of N/10 sulphuric acid is equivalent to 0.02852 g. of anhydrous morphine. —(*British Pharmacopœia Commission Report*, No. 12, May 1939.)

Morphinæ Sulphas (B.P. Add. IV).
 $(C_{17}H_{19}O_3N)_2.H_2SO_4, 5H_2O = 758.5$. Contains 74.0 to 75.5% of

anhydrous morphine. Determined by the method described under morphine hydrochloride. Other alkaloids, not more than 1.5%. Loss on drying at 120°, not more than 12%. Ash, not more than 0.1%. *Morphinæ Sulfas*, *U.S.P. XII*, allows the same moisture limit, but dries at 130°. Tests for acidity, ammonium salt, meconate and foreign alkaloids are included. On exposure to air, loss of water of crystallisation may result.

Tabellæ Morphinæ Sulfatis (*U.S.P. XII*). Contain 93 to 107% of the labelled amount of $(C_{17}H_{19}O_3N)_2 \cdot H_2SO_4 \cdot 5H_2O$, including all tolerances. Assayed by transferring a weighed quantity of powdered tablets to a separator, using distilled water faintly acidified with hydrochloric acid, making alkaline with ammonia solution, completely extracting with chloroform-alcohol mixture (4:1), washing the combined extracts with water and extracting the aqueous washings with a further portion of chloroform-alcohol mixture. After filtration of the combined extracts, the organic solvent is removed, excess N/50 sulphuric acid added, and the excess acid titrated with N/50 sodium hydroxide, using methyl red indicator. The assay is applicable to hypodermic tablets, but for other tablets a suitable modification of the above method may be necessary.

Tabellæ Morphinæ et Atropinæ Sulfatum (*N.F. VII*). Contain 91 to 109% of the labelled amount of morphine sulphate, including all tolerances. Assayed for morphine sulphate by dissolving as completely as possible in 3% solution of sodium hydroxide saturated with sodium chloride, extracting with ether and rejecting the ether. The solution is neutralised with hydrochloric acid and 0.5 ml. of acid added in excess. Alcohol and a chloroform-alcohol mixture (9:1) are added and the mixture carefully rendered faintly alkaline with ammonia solution, and the alkaloid completely extracted with successive portions of solvent. The filtered and washed chloroform-alcohol solution is evaporated until nearly dry, excess N/20 sulphuric acid added, and the cooled solution titrated with N/50 sodium hydroxide, using methyl red indicator.

Morphinæ Tartras (*B.P.*). $(C_{17}H_{19}O_3N)_2 \cdot C_4H_6O_6 \cdot 3H_2O = 774.4$. Loss at 100°, not more than 7%. Ash, not more than 0.1%. Complies with the limit test for other alkaloids.

Papaveretum (*B.P.C.*). Contains from 47.5 to 52.5% of anhydrous morphine. Assayed by the *B.P.C.* process: extract 1 g. in 20 ml. of water and 5 ml. of N/1 sodium hydroxide with successive portions of 50 ml. and 25 ml. of ether; transfer the aqueous liquid (filtering if necessary) to a 50 ml. flask, and also washings of the ether layers with 2.5 ml. of N/1 sodium hydroxide with 5 ml. of water, and 5 ml. portions of water until 50 ml. has been collected; then transfer to a conical flask, add 5 ml. of alcohol and proceed as the *B.P.* assay for Opium, collecting the morphine on a small filter paper, and adding a correction of 0.025 g. of morphine to the amount indicated by the titration. Opium concentratum, *P.G. VI*, is a mixture of the hydrochlorides of opium alkaloids containing 48 to 50% of morphine.

Papaverina (*B.P.C.*). $C_{20}H_{21}O_4N = 339.2$. M.p., 146° to 147°. Ash, not more than 0.1%. *Papaverinæ Hydrochloridum*, *N.F. VII*, complies with tests for morphine and cryptopine, thebaine, or other inorganic impurities; ash, not more than 0.5%. *Papaverinum hydrochloridum* is official in the *P.G. VI* and in the *Fr. Cx.* 1937.

Thebaine Hydrochloride. Thebainum hydrochloridum is official in the *P. Helv. V*, and contains when dried not less than 99% of $C_{15}H_{21}O_2N \cdot HCl$; it should contain from 2 to 3% of water corresponding to approximately half a molecule of water.

VOLECITHINUM

Lecithin is a mono-aminophosphatide. Phosphatides are complex bodies of more or less fatty nature which can be extracted from tissues by alcohol, ether, etc., and which contain fatty acids, nitrogen and phosphorus. They are of unstable composition.

On hydrolysis lecithin yields stearic acid, glycerophosphoric acid and choline.

Ovolecithinum (B.P.C.) is the lecithin prepared from dried egg-yolk and is required to contain 3.5% of phosphorus.

Lecithins may be derivatives of either stearic, palmitic, or oleic acid, alone or mixed. Ovolecithin is generally assumed to be mainly stearyl, i.e., **choline-distearylglycerophosphate**, and plant lecithin to be mainly an oleic acid body, but the fatty acids are not determined with certainty.

Lecithin Content of Various Substances in percentages—

| | | | |
|----------------------------|------|-----------------------|------|
| Brain | 16.0 | Egg Yolk | 12.0 |
| Heart | 4.5 | Peas | 1.2 |
| Liver | 4.3 | Lupin Seeds | 2.0 |
| Kidneys | 8.5 | Ergot | 1.7 |
| Lung | 1.5 | Yeast (dry) | 2.0 |
| Spinal Cord | 11.0 | Barley | 0.7 |
| Nerve Tissue (dry) | 17.0 | Wheat and Rye | 0.6 |
| Blood Corpuscles | 0.46 | Green Peas | 0.15 |
| Mushrooms | 0.9 | | |

If the cadmium compound of "lecithin" is recrystallised from a mixture of ethyl acetate and 80% alcohol the true lecithin can be freed from kephalin and then liberated from its cadmium compound by means of ammonium carbonate.

Determination of Lecithin in Preparations. Extract 1 g. to 2 g. of a lecithin preparation, or 5 g. to 20 g. of a food stated to contain it, with 96% alcohol—first in the cold and then twice under a reflux condenser. Then extract the insoluble portion with boiling chloroform 2 hours. The combined alcohol and chloroform extractives are evaporated and the residues are digested for 2 hours with 100 ml. of chloroform to separate the lecithin from phosphoric acid, glycerophosphoric acid, etc. To estimate phosphorus pentoxide in the purified extractive, incinerate and oxidise with sulphuric and nitric acids or ignite with magnesium oxide, and bring to weight as pyrophosphate in the usual manner. The factor 11.36 is used to convert the amount found of P_2O_5 into lecithin.

Lecithin is used as an emulsifying agent, especially in the manufacture of chocolate and other confectionery.

C.I.S. Method for Determination of Phosphorus.

The second report of the Commission Internationale des Spécialités includes an agreed method for the determination of phosphorus in organic substances such as lecithin in which the phosphoric acid obtained by treatment with sulphuric and nitric acids is precipitated by means of ammonium molybdate. The washed precipitate, which has approximately the composition $(NH_4)_3PO_4 \cdot 12MoO_3 \cdot 2HNO_3$, is heated with excess of N/2 sodium hydroxide until all ammonia is removed, and the excess of alkali is titrated with N/2 acid using phenolphthalein as indicator. If theoretical equivalents are used the results are slightly low; correct results are obtained by regarding each ml. of N/2 sodium hydroxide as equivalent to 0.560 mg. of P or 1.28 mg. of P_2O_5 .—*Bull. Féd. int. Pharm.*, 1938, 34.

Lipoids are an essential in the food of animals. Among the lipoids there is a series of definite phosphatides, of which the molecule consists of glycerophosphoric acid and a fat acid with a nitrogenous base. Each organ of the body elaborates one or more specific lipoids. Organs or glands which are insufficient or impaired are found to lack lipoids, their power to elaborate them from the materials of the blood being diminished.

OXYGENIUM

Oxygenium (*B.P. Add. I*). $O = 16.000$. Contains not less than 98% *v/v* of O_2 , the residue consisting of argon with a trace of nitrogen, or of hydrogen. Assayed by absorption in one-fifth its volume of alkaline solution of pyrogallol. The turbidity produced in barium hydroxide solution should not exceed that produced by sodium bicarbonate solution equivalent to a limit of CO_2 of approximately 0.0002% *v/v*. Limit tests for halogens and oxidising substances are included. The colour of 100 ml. of water with litmus solution is not changed by 2 litres of gas, by the test for limit of acidity and alkalinity in Nitrogenii Monoxidum—a volume equivalent to 2 litres of the gas at N.T.P. is passed through 100 ml. of boiled water and methyl red solution with 0.2 ml. of N/100 acid; the colour is not more pink than a similar mixture and not more yellow than the water and methyl red with 0.1 ml. of N/100 acid. Oxygenium, *U.S.P. XII*, contains not less than 99% *v/v* of O_2 . The limit of carbon dioxide is one-quarter of that of the *B.P.*; it is assayed by measurement of the residual gas after interaction with ammonium chloride and ammonium hydroxide solution in contact with a copper spiral. The residual gas from approximately 1 litre after absorption in alkaline sodium hydrosulphite solution, shaken with diluted blood, and pyrogallol and tannic acid added shows no pink coloration and no more grey colour than that produced in a blank test using carbon monoxide-free oxygen. Tests for limit of acid, alkalis and halogens are included.

Nitrogenii Monoxidum (*B.P.*). Nitrous oxide drawn from a cylinder in the upright position, contains not less than 93% *v/v* of N_2O . Carbon monoxide limit, determined on the first portion of the gas drawn from an upright cylinder, 50 parts per million *v/v*. Complies with tests for absence of halides and sulphuretted hydrogen, arseniuretted hydrogen and phosphoretted hydrogen, and with limit tests for water vapour, carbon dioxide, uncondensable gases, acidity or alkalinity, reducing substances and oxidising substances. Oxidum Nitrosum, *U.S.P. XII*, complies with tests for carbon dioxide, halogens, reducing substances, and oxidising substances. A test for limit of acids or alkalis is included. The volume of uncondensable gas in the assay process is not more than 5%, indicating not less than 95% *v/v* of N_2O in the gas tested.

PANCREATINUM

Pancreatinum (*B.P.*). Possesses not less than a minimum activity in respect to trypsin, lipase and amylase. To determine the activity due to trypsin, 50 ml. portions of skimmed milk, standardised to protein content, are adjusted to pH 8.0 with N/20 sodium hydroxide using phenol red as external indicator; one portion is boiled and 10 ml. of a 0.5% boiled solution of the

substance added and to the second portion 10 ml. of a 0.5% solution is added, both are heated rapidly and maintained at 38° to 40° for 1½ hours, cooled rapidly and neutralised with N/20 sodium hydroxide to phenolphthalein. Add to each 5 ml. of neutralised solution of formaldehyde and titrate with N/20 sodium hydroxide to phenolphthalein; the boiled mixture requires 4.9 to 5.1 ml. and the other 9.0 to 13 ml. Activity due to lipase is determined by digestion of two 10 ml. portions of a suspension of separated cream in N/10 sodium carbonate containing 0.2% *v/v* of oleic acid and adjusted with acetic acid to pH 8.0, one with 1 ml. of a 1% solution of the pancreatin and the other with 1 ml. of the same solution previously boiled, at 38° to 40°, for 4 hours; after dilution with an equal volume of alcohol, the titration with N/20 sodium hydroxide to phenolphthalein should be not less than 1.0 ml. Amylase is determined by adding to 5 ml. portions of a 0.1% starch mucilage containing 0.5% salt, 0.35, 0.40, 0.45, 0.50, 0.55 and 0.60 ml. of a 0.02% solution of the pancreatin and maintaining at 40° for one hour; after cooling rapidly to 20° and adding one drop of N/10 iodine to each, the portions with addition of 0.5 ml. or more should show no blue colour.

Pancreatinum, *U.S.P. XII*, converts not less than 25 times its weight of starch into soluble carbohydrates and not less than 25 times its weight of casein into proteoses. Pancréatine, *Fr. Cx.* 1937, assayed for proteolytic action by digestion of pork fibrin and titration of the amino-acids produced, yields amino-acids calculated as aminoacetic acid equivalent to not less than 18% of the fibrin; assayed for lipolytic action by titration of the acids produced on reaction with monobutyryne, corresponds to not less than 20% of monobutyryne hydrolysed; and for amylolytic action by titration of the sugars produced on digestion of potato starch.

Assay of Proteolytic Activity. The *B.P.* method is lengthy, the end-point is difficult to observe and the pH should be adjusted before the addition of the formaldehyde. The following assay is based on a formol titration of digested casein.

Casein solution. Dissolve 4 g. of Hammarsten's casein in 90 ml. of water containing 3 ml. of N/1 sodium hydroxide, adjust to pH 8.7, using phenolphthalein as external indicator and dilute to 100 ml.

Neutral standard. To 10 ml. of the *B.P.* phosphate buffer solution at pH 7.0 add one drop of 0.1% solution of neutral red in alcohol (50%).

Alkaline standard. To 10 ml. of the *B.P.* boric acid-potassium chloride-sodium hydroxide buffer solution at pH 8.7 add one drop of 0.1% solution of neutral red in alcohol (50%) and 3 drops of 0.1% solution of phenolphthalein in alcohol (50%).

Preparation of the enzyme solution. Triturate the required weight of the sample with a little chloroform water in a small mortar, wash into a 100 ml. graduated flask and make up to volume with chloroform water. The liquid should not be filtered but should be used as a suspension if insoluble matter is present.

Digestion. Mix 30 ml. of the casein solution and a definite volume of the enzyme solution. Dilute with water to 100 ml., remove 50 ml. as a control and heat the remainder rapidly to 55° keeping at this temperature for 20 minutes. Cool rapidly to laboratory temperature. Add 5 drops of neutral red solution to both liquids and N/10 acid or alkali to both until each colour matches the neutral standard. (This is most easily done by pouring 10 ml. into a test-tube and comparing with the standard in a similar tube.) Add 15 drops of 0.1%

phenolphthalein solution and 10 ml. of formaldehyde solution (B.P.) to both liquids. Titrate with N/10 alkali until the colour matches the alkaline standard. The difference between the two titrations represents the amino-acids formed. The result is preferably expressed as a volume of standard alkali for a definite weight of the enzyme preparation. A convenient method of expression is as the number of ml. of N/1 sodium hydroxide for 1 g. of the sample. The quantity of sample used must be adjusted so that the final titration lies between 4.3 and 4.7 ml.

In the final titration the neutral red changes from pink to yellow before the pink of the phenolphthalein appears. Consequently there is a point in the first colour change at which the tint matches that of the alkaline standard. This must be disregarded. The end-point is reached during the change from yellow to pink.

A reasonable standard for pancreatin would be that 1 g. by the above method should require not less than 15 ml. of N/1 sodium hydroxide in the titration.—N. Evers and W. Smith, *Quart. J. Pharm.*, 1936, 393.

The following assay is recommended by the Sub-Committee on General Organic Chemicals of the Committee on General Chemistry:—Dissolve 4 g., accurately weighed, of purified casein in 90 ml. of water containing 3 ml. of N/1 sodium hydroxide, adjust the pH of the solution to 8.7 and make up the volume to 100 ml. with water. Triturate 0.5 g. of the pancreatin with chloroform water and make up the volume to 100 ml. with chloroform water. Mix 10 ml. of the unfiltered liquid with 30 ml. of the casein solution and make up to 100 ml. with chloroform water. Measure 50 ml. of the mixture into a small flask and heat rapidly to 55°, keeping at this temperature for twenty minutes. Cool rapidly to laboratory temperature. Add 5 drops of solution of neutral red both to the digested liquid and to the 50 ml. which remains undigested. Add to both liquids N/10 sodium hydroxide or N/10 hydrochloric acid until the colour matches the colour produced by mixing 10 ml. of solution of standard pH 7.0 and one drop of solution of neutral red. Add 15 drops of solution of phenolphthalein 0.1% and 10 ml. of solution of formaldehyde to each liquid. Titrate both liquids with N/10 sodium hydroxide until the colour matches the colour produced by mixing 10 ml. of solution of standard pH 8.7, 1 drop of solution of neutral red and 3 drops of solution of phenolphthalein 0.1%. The difference between the two titrations should be not less than 4.5 ml.—(*British Pharmacopœia Commission Report*, No. 14, September 1939.)

Determination of Lipase. A 1—1000 agar solution is adjusted to pH 7, autoclaved at 120° for 15 minutes and filtered while hot, and 20 ml. portions are sterilised in tubes by heating at 115° for 20 minutes. Into a 60 ml. glass-stoppered flask are placed in order glycine 0.6 g., N/1 sodium hydroxide 2 ml., distilled water at 40° 8 ml., and 40 mg. of 1% pancreatin in lactose. The mixture is shaken, 10 ml. of the agar solution (warmed to 40°) is added and 1.5 ml. of tributyrin. The liquid is shaken and maintained at 40° for 2 hours, being shaken for 30 seconds every 5 minutes for the first half-hour and then for 30 seconds every 10 minutes. The pH must remain greater than 8.4. At the end of the 2 hours the action of the enzyme is stopped by adding 1 ml. of 10% sodium metaphosphate and 5 ml. of N/1 sulphuric acid. The liquid is cooled and extracted four times with ether, using 50 ml. for the first extraction and 25 ml. subsequently. The ethereal extract is washed with two quantities of 2 ml. and 1 ml. respectively, of water, diluted with 50 ml. of dehydrated alcohol and 10 ml. of water, and titrated to bromophenol blue with N/10 sodium hydroxide. A blank test is made on an aqueous solution boiled for 2 minutes. The difference in the titration values should be not less than 10 ml.—H. Penau and J. Guilbert, *J. Pharm. Chim., Paris*, i/1937, 5.

Papainum (B.P.C. Supp. IV). Assayed by the B.P.C. '34 process: 0.2 g. in a few ml. of water is washed into 30 ml. of a neutral 4% casein solution, 10 ml. of N/10 sodium carbonate added and diluted to 50 ml.; a 20 ml. portion with 20 ml. of water and 20 ml. of neutral formaldehyde solution is titrated with N/10 hydrochloric acid to phenolphthalein; the remaining 30 ml. of the solution is maintained at 37° for 6 hours and a 20 ml. portion titrated as before; calculated from the difference between the titrations, the amino-acids produced by 1 g. of papain require for

TABLE OF THE COMMON ENZYMES AND FERMENTS

| ENZYME OR FERMENT | CHIEF SOURCE | SUBSTRATE AND PRODUCT(S) |
|--|---|--|
| Amylase and Diastase .. | Human saliva, malt and pancreas. | Hydrolyses starch, forming dextrin and maltose. |
| Catalase (<i>see also Peroxidase</i>) .. | Blood, most animal and plant juices. | Decomposes hydrogen peroxide and other peroxides. |
| Cellulase .. | Grass-eating animals. | Converts cellulose into sugar, as in the case of gramini-voracious feeders. |
| Emulsin .. | Almonds. | Hydrolyses glycosides, e.g., amygdalin. |
| Erepsin | Mucous membrane of small intestine. | Forms simple amino-acids from proteoses and peptones. |
| Fibrin Ferment (<i>see Thrombin</i>) | | |
| Inulase | Inula helenium and squill. | Decomposes inulin, forming fructose. |
| Invertase or Sucrase .. | Intestinal juice and yeast. | Can convert many times its own weight of cane sugar into glucose and fructose. |
| Lactase | Animal body. | Converts lactose into glucose and galactose. |
| Lactic Acid Ferment (organised) | Lactic acid bacteria, <i>q.v.</i> | Converts lactose into lactic acid. |
| Lipase | Pancreatic juice and seeds of plants. | Converts fat into fatty acids and glycerol. |
| Myrosin | Mustard seeds. | Hydrolyses the mustard glycoside in the presence of water. |
| Oxidases (<i>see Catalase and Peroxidase</i>) | | |
| Papain | The juice of <i>Carica Papaya</i> . | Digests proteins in acid or alkaline solution. |
| Pepsin | Stomach, e.g., pigs. | Converts proteins into meta-protein, proteoses and peptone, in acid solution only. |
| Peroxidase .. | Blood, milk and many plant tissues, e.g., potato and fungi. | Oxidiser. Sets free oxygen from H_2O_2 . When an organic peroxide is in the plant tissue the system is called oxidase. |
| Perhydridase .. | Ditto. | Reducing agent. |
| Ptyalin | Saliva of the mouth. | Converts cooked starch into dextrin and maltose. |
| Rennin or Chymosin .. | Stomach of sucking animals, e.g., calf. | Coagulates the casein in milk, effecting clotting. |
| Steapsin, or Lipolytic Ferment | <i>See Lipase.</i> | |
| Thrombin .. | Blood, after it is shed, in the presence of Ca salts. | Coagulates fibrinogen into fibrin, forming the clot. |
| Trypsin | Pancreas. | Converts proteins into amino-acids and a polypeptide in dilute alkali. |
| Urease | The soya bean and in urine, especially in catarrh of bladder. | Converts urea into ammonium carbonate. |
| Zymase | Yeast. | Converts sugars into alcohol and CO_2 . |

neutralisation not less than 20 ml. of N/10 sodium carbonate. Ash limit, 10%. The *Fr. Cx.* 1937 estimates the proteolytic action of papain by digesting a mixture of 0.015 g. with 2.5 g. dried pork fibrin and 50 ml. water at 70° for 2 hours; after filtering 10 ml. of the filtrate does not show any change with 20 drops of nitric acid; 10 ml. evaporated to dryness weighs not less than 0.3 g. and in a 2 decimetre tube has a rotation of not less than -2.4° ; loss at 102°, not more than 12%; ash not more than 12%.

Pepsinum (B.P.). Dissolves not less than 2500 times its weight of coagulated egg albumen. Assayed by digestion, at 40° to 41° for 6 hours, of a solution of pepsin and salt in water acidified with hydrochloric acid with a trituration of freshly prepared egg albumen in acidified water, when no granules should be visible and the liquid not more than faintly opalescent. Pepsinum, *N.F. VII*, should digest 3000 to 3500 times its weight of freshly coagulated and disintegrated egg albumen. The digestion is conducted at 52° during 2½ hours, and the volume of undigested albumen measured with comparison to a Reference Pepsin solution. The *Fr. Cx.* 1937 requires that pepsin shall convert 50 times its weight of dried fibrin, corresponding to a proteolytic value of 200:—digest 1% pepsin solution, 5 ml., N/1 hydrochloric acid; 4.3 ml., fibrin, 2.5 g., water, 60 ml., for 6 hours at 50°. The pH of the liquid should then be 3.4. Test the filtrate with nitric acid. Pepsine Amylacée and Pepsine Lactosée correspond to the above test using a solution containing 2.5 g. in 100 ml., which corresponds to a proteolytic value of 80. Pepsinum, *P. Helv. V*, is standardised against a known weight of casein and diluted if necessary with lactose; the moisture should not exceed 5% and the ash 3.5%.

The *B.P.* assay process, retained from the *B.P.* '14, is unsatisfactory, and should never be used except as an empirical limit test, since it does not measure the amount of egg albumen dissolved. Pepsin is only manufactured in two strengths, and dilution of the lower strength should not have been sanctioned.—*Pharm. J.*, ii/1932, 146.

After consideration of a number of methods proposed for the assay of pepsin, that described by Cole (*Practical Physiological Chemistry*, 9th Edn., p. 228) based on the clotting of calcified milk, is recommended.—A. C. Munro and R. Seifert, *Pharm. J.*, i/1933, 482.

For a method depending on the digestion of soluble casein see under *Ventriculus Desiccatus*, p. 204.

As the result of the examination of 13 different samples of pepsin, it is concluded that commercial pepsins on the English market to-day are of good quality. A discussion and comparison of the *B.P.*, *U.S.P.*, *P.G.*, and edestin methods of assay are given, and figures are deduced showing the comparative severity of the tests. Suggestions are made for an improved official assay process. The greatest obstacles in the way of obtaining comparable results in the testing of pepsins is shown to be the variability of the substrate. In the case of egg-white, two methods of overcoming this difficulty are:—(a) the setting-up of a standard pepsin with which other pepsins are to be compared in tests using the same egg-white for tests and standard, or preferably (b) the use of a method of averaging the results of several tests.—K. Bullock, *Quart. J. Pharm.*, 1935, 13.

Carminic Fibrin; prepared by washing blood fibrin with ammoniacal solution of carmine, is a dark-coloured mass, easily crumbled, which yields no colour to water or 0.1% hydrochloric acid until the fibrin contained in it has been dissolved by a ferment; hence its use as a simple quantitative test for pepsin by noting the time required to give a pink colour equal to that of a standard or control.

Pepsin Solution. Loss of activity on storage. A mixture containing pepsin in acidified chloroform water showed a reduction of 40% in activity after a fortnight. A concentrated solution, containing 4 g. per fluid ounce of chloroform water but no acid, was stable.—A. C. Munro and R. Seifert, *Pharm. J.*, i/1933, 432.

Peptonum. The *Fr. Cx.* 1937 requires Peptone Pancréatique to contain about 14.5% of total nitrogen. 0.5 g. in 50 ml. water titrated with N/10 soda to phenolphthalein, should require about 8 ml. and on the addition of 10 ml. of neutralised formaldehyde solution and further titration should require about 20 ml. for neutralisation of the amino-acids; the ratio of nitrogen of amino-acids to total nitrogen should be greater than 0.2. Peptone Pepsique, *Fr. Cx.* 1937, should contain about 14.5% of total nitrogen and the ratio of amino-acid nitrogen to total nitrogen should be less than 0.2.

Meat Extract.

Extractum Carnis (N.F. VII). Total solids, not less than 75%; ash, not more than 30% of the total solids; sodium chloride, determined on the ash, not more than 10% of the solids; alcohol-insoluble solids, dried at 110°, not more than 10% of the solids. Nitrogen content of alcohol-soluble solids determined on the alcoholic filtrate from the insoluble solids by the Kjeldahl method, not less than 6%; NH_3 , not more than 0.35% of the total solids determined by distillation of 100 ml. of the solution of the extract with 5 g. barium carbonate and 100 ml. water.

Methods for the determination of constituents of meat extracts are described in *Methods of Analysis (A.O.A.C., 1940, 384 et seq.)*. The tentative method for ammonia consists of aspirating a series of tubes so that the air passing through a sulphuric acid (1+9) wash bottle passes through a tube containing the extract with 1 ml. of saturated potassium oxalate solution, a few drops of kerosene and sufficient sodium carbonate solution to make just alkaline, and into a titration tube containing standard acid.

Tentative Methods for Amino Nitrogen.

Van Slyke Method: The filtrate from a water-extract boiled with 1 ml. of N/1 acetic acid is shaken with glacial acetic acid and sodium nitrite solution (3%), the nitrous oxide and nitrogen formed shaken with potassium permanganate, and potash solution and the unabsorbed nitrogen measured, correcting for a blank determination on the reagents.

Sorensen Method: To 20 ml. of the filtrate from which the coagulable and insoluble nitrogen have been removed as in the above process and neutralised to phenolphthalein, 10 ml. of neutralised formaldehyde is added and the mixture titrated with N/5 barium hydroxide, adding a slight excess and back titrating with N/5 hydrochloric acid. A blank determination is made and the nitrogen present as free ammonia subtracted.

Seriparium (B.P.C.). Rennet (rennin) should comply with the following test:—Mix 0.1 g. with 50 ml. of water, allow to stand for 15 minutes and add 1 ml. to 50 ml. of milk, of acidity to phenolphthalein equivalent to 0.14 to 0.15% of lactic acid, warmed to 43° in a beaker about 12 cm. high and 5 cm. in diameter; stir slowly for 10 seconds and maintain at 43°; thickening commences within 10 minutes, and a firm curd is produced within an additional 30 seconds, indicating coagulation of not less than 25,000 times its weight of fresh cows' milk. Renninum, *N.F. VII*, is standardised by addition of 1 ml. of rennin solution (0.2%) to 50 ml. of well-mixed cows' milk at 43°, stirring for 10 seconds and timing the period taken for thickening as shown by a convex surface when the vessel (12 cm. high and 4.5 cm. diameter) is tipped at an angle of 45°; it coagulates in 90 to 110% of the time

taken by a reference rennin solution. The reference solution is prepared from a powdered rennin, the stability and standards of which have been definitely established over a number of years, coagulating approximately and not less than 25,000 times its weight of fresh cows' milk.

Rennin differs considerably from pepsin. It is a decomposition product of protein, of acid albumin type, not precipitated by boiling the solution (*cf.* pepsin). It dialyses through parchment but is hydrolysed in the process (the main bulk in the case of pepsin its not dialysed). Rennin is precipitated on saturating the liquid with sodium chloride. Proteolytic activity does not seem to be a part of the true physiological characteristics of rennin.—*J. Amer. chem. Soc.*, 1923, 249, per *Chem. & Drugg.*, i/1923, 437.

PARAFFINUM

Paraffinum Durum (B.P.). M.p., 50° to 60°. Ash, not more than 0.05%. Paraffinum, *N.F. VII*, melts between 47° and 65°, and complies with a test for carbonisable substances.

Paraffinum Liquidum (B.P. Add. I). Sp. gr., 0.880 to 0.895. Kinematic viscosity, not less than 64 centistokes at 37.8°. In the sulphuric acid test, the acid layer is separated from the heated mixture and when viewed in a cell in a colorimeter is not deeper in colour, either in respect to red or yellow components, than the combination of colour glasses prescribed. Petrolatum Liquidum, *U.S.P. XII*, has a kinematic viscosity of not less than 38.1 centistokes at 37.8°. Sp. gr. at 25°, 0.860 to 0.905. Huile de Vaseline Fluide, *Fr. Cx.* 1937, should have a viscosity of 10 to 16 centistokes; water and alcohol boiled with it should be neutral to bromothymol blue.

The important test for impurities with sulphuric acid is now carried out with nitrogen-free sulphuric acid, the strength of which is 96%. Probably most chemists have used 98% acid for this test, and the reduction in strength makes a very great difference in the amount of impurity which the test will detect, and the change may lead to a lowering in the standard of purity. Probably the taste is the most important point about the oil, and it is unfortunate that no standard for this quality can be laid down.—*N. Evers, Pharm. J.*, i/1933, 195.

Deterioration of Liquid Paraffin during Storage.

Some samples of liquid paraffin develop objectionable odours on standing. The following test for the formation of peroxides during autoclaving indicates the degree of deterioration to be expected on long storage. Place 100 ml. of the sample in a wide-mouthed 8 oz. screw-capped jar (with lining removed from cap), loosely replace cap and autoclave at 20 lb. pressure for one hour. To 10 ml. of cooled autoclaved oil in a test-tube add 5 ml. of testing solution (*infra*); replace air in the test-tube by carbon dioxide or nitrogen, cork tightly and shake for 30 seconds. A pink or red colour in the aqueous layer denotes the presence of peroxides and indicates that the sample is liable to deteriorate on storage. The testing solution is made as follows:—*Solution A*.—10 g. of ferrous sulphate is dissolved in 500 ml. of water to which has been added 10 ml. of sulphuric acid and 1 g. of potassium thiocyanate. When solution is complete 1000 ml. of commercial acetone is added and the mixture refluxed in the presence of bright iron wire, a stream of carbon dioxide or nitrogen being simultaneously passed through it. The colourless solution is stored over bright iron wire in a bottle in which the air is replaced by an inert gas. *Solution B* is a 2% w/v solution of potassium thiocyanate. For use mix 3 volumes of solution A with 1 volume of solution B and store out of contact with air in a bottle containing bright iron wire. It is ready for use when it is colourless or has a slate-grey cast.—*P. L. Burrin, A. G. Worton, and F. E. Bibbins, J. Amer. pharm. Ass.*, 1936, 27.

FOR

able for thick

le as Oleum

s.

Paraffinum Liquidum Leve (*B.P. Add. IV*). Sp. gr., 0.835 to 0.875. Kinematic viscosity, not greater than 33.1 centistokes at 37.8°. Limits of sulphur compounds and of acidity are included. *Petrolatum Liquidum Leve, U.S.P. XII*, has a kinematic viscosity of not more than 37 centistokes at 37.8°. Sp. gr., 0.828 to 0.880.

Paraffinum Molle Album (*B.P.*). n_{D60}° , 1.453 to 1.460; m.p., 40° to 46°. Volatilises without acrid odour and complies with tests for acidity, fixed oils, soaps and resins. The *B.P. Add. VI* states that yellow soft paraffin may be used or supplied in place of white soft paraffin. *Petrolatum Album, U.S.P. XII*, complies with the tests for *Petrolatum, U.S.P. XII*.

Paraffinum Molle Flavum (*B.P.*). n_{D60}° , 1.460 to 1.474; m.p., 38° to 46°; ash limit, 0.05%. Volatilises without acrid odour and complies with tests for acidity, fixed oils, soaps and resin. *Petrolatum, U.S.P. XII*, melts between 38° and 60°; sp. gr. at 60°, 0.815 to 0.865; ash, not more than 0.05%.

The lower limit of melting-point of yellow soft paraffin has been lowered from 42° to 38°, and the latter now includes Vaseline.—N. Evers, *Pharm. J.*, i/1933, 195.

A simple test is prepared to distinguish between "natural" and "artificial" soft paraffin. The test consists in determining the deposition temperature or solution temperature of a solution of the soft paraffin in a mixture of glacial acetic acid and carbon tetrachloride. The volumes of crystalline deposit, if any, and of the upper oily layer which separates are also determined. Freedom from adulteration with liquid paraffin and hard paraffin is indicated by (1) a high solution temperature, (2) a low volume of crystalline deposit and (3) a considerable volume of separated upper oily layer.—H. Brindle, *Quart. J. Pharm.*, 1939, 361.

Iodine Value. A modification of the Wijs method giving fairly constant results is described. The *B.P.* method is unsuitable because soft paraffins are largely insoluble at ordinary temperatures in the reagents used, and the pyridine sulphate bromide method has no special advantages. Using the method described, 18 samples of yellow soft paraffin gave an average iodine value of 9.6, and 19 of white soft paraffin gave an average value of 5.1. As a rule there was a close relationship between the iodine values of soft paraffins and their tendency to become overheated in the preparation of bleach ointment, the higher the value, the greater the tendency towards over-heating.—H. Brindle, *Analyst*, 1940, 409.

Petroleum Leve (*B.P.C.*). Not less than 95% distils between 40° and 60°, the sp. gr. of which is 0.620 to 0.700. Residue on evaporation, not more than 0.002% *w/v*. *Benzinum Purificatum, U.S.P. XII*, has a sp. gr. at 25° of 0.634 to 0.660. Distils completely between 35° and 80°. Residue on evaporation not above 40°, not more than 0.002%.

Cera Alba (*B.P.*). Acid value, 18 to 24; the wax complies with the other constants and tests for *Cera Flava*. *Cera Alba, U.S.P. XII*, has an acid value of 17 to 24, an ester value of 72 to 79, and responds to the other tests for *Cera Flava, U.S.P. XII*.

Cera Flava (*B.P. Add. I*). Sp. gr., 0.958 to 0.970; m.p., 62° to 64°; n_{D60}° , 1.4380 to 1.4420. Acid value, by titration in absolute alcohol with N/2 alcoholic potassium hydroxide, 17 to 23. Ester value, 70 to 80. Ratio number of 3.3 to 4.2. *Cera*

Flava, *U.S.P. XII*, has an acid number of 18 to 24, and an ester number of 72 to 77.

Cetaceum (*B.P.C.*). M.p., 42° to 50°; $n_{D, 80^{\circ}}$, about 1.4330. Acid value, not more than 1.0. Saponification value, 120 to 136. Iodine value, 3 to 4.4. Cetaceum, *U.S.P. XII*, has a sp. gr. of about 0.94 at 25°. M.p., 42° to 50°. Tests for paraffin and free acids and for stearic acid are included.

PELLETIERINA

Pelletierinæ Tannas (*B.P.*). Residue on ignition, not more than 0.1%. An acidified solution yields no precipitate with platinic chloride solution. Pelletierinæ Tannas, *U.S.P. XII*, should yield not less than 20% of residue by extraction with chloroform from alkaline solution, evaporation with 0.1 ml. of hydrochloric acid, and drying for one hour at 60°.

Granati Radicis Cortex (*B.P.C.*). Contains not more than 2% of wood or other foreign organic matter. Écorce de Grenadier, *Fr. Cx.* 1937, contains not less than 0.25% of alkaloids by the following process:—Macerate 15 g. of the dried drug for 2 hours with 5 g. calcined magnesia and 10 ml. water, and then reflux with 150 ml. of chloroform for 1 hour. After readjustment, evaporate 100 ml. of the filtered chloroform to 40 ml., transfer to a separator with 40 ml. of ether and extract with 10 ml. of N/10 hydrochloric acid and 20 ml. water, followed by 2 portions of 20 ml. water; back titrate the acid liquids with N/10 potash using methyl red indicator; 1 ml. N/10 acid = 0.01475 g. alkaloid. Cortex Granati, *P.G. VI*, should yield not less than 0.4% of alkaloid. Cortex Granati, *P. Helv. V*, is standardised to yield not less than 0.5% of alkaloid.

It is shown that Ewer's Method (*Arch. Pharm.*, 1899, 237, 53, 56) for the estimation of the alkaloids of pomegranate bark gives fairly accurate results, that it is possible to remove the inactive pseudo-pelletierine from the total alkaloids and that commercial "pelletierine" salts are apt to be low in "pelletierine" content and therefore of doubtful value as tænicides.—H. J. A. Goodson, *Quart. J. Pharm.*, 1940, 56.

PHENACETINUM

Phenacetinum (*B.P.*). $C_{10}H_{13}O_2N = 179.1$. M.p., 134° to 136°. Ash, not more than 0.05%. Complies with tests for neutrality, readily carbonisable substances, acetanilide and *p*-phenetidine. Acetophenetidinum, *U.S.P. XII*, melts between 134° and 136°. Ash, not more than 0.05%.

Tabellæ Acetophenetidini (*U.S.P. XII*). Contain 94 to 106% of the labelled amount of $C_{10}H_{13}NO_2$, including all tolerances. Assayed by extraction of a weighed quantity of powdered tablets with chloroform after preliminary extraction with light petroleum, removal of the chloroform and weighing the residue, dried at 60°.

Tentative Method for the Determination of Phenacetin and Acetanilide in Mixtures. *Methods of Analysis* (A.O.A.C., 1940, 560). 0.2 g. of the mixture is heated with 2 ml. glacial acetic acid and diluted with 40 ml. of water at 70°. To the clear liquid 25 ml. of iodine solution (3% of purified iodine and 4% of potassium iodide, standardised to thiosulphate) and 3 ml. of hydrochloric acid are added. When crystallisation commences the mixture is allowed to cool and stand, and the crystals of periodide filtered off. The excess iodine in the filtrate is titrated with a standard thiosulphate solution or the iodine removed from the crystals with a little sodium thiosulphate and the phenacetin extracted with chloroform. Acetanilide is determined in the filtrate from the phenacetin periodide, decolourised with thiosulphate; a slight excess of sodium bicarbonate followed by 1 or 2 drops of acetic anhydride are added and the liquid extracted with chloroform. The chloroform is evaporated to low bulk and digested on a steam-bath with sulphuric acid (1+9), hydrochloric acid is added and the liquid titrated with N/10 bromine. Details for the removal of caffeine and antipyrine, if present, are given.

Tentative Method for the Determination of Phenacetin and Caffeine. *Methods of Analysis* (A.O.A.C., 1940). For caffeine the product obtained by the gross separation of the caffeine-phenacetin mixture in chloroform is treated with 10 ml. of sulphuric acid (1+9) and heated on the water-bath until the volume is reduced to 5 ml. This is treated with 10 ml. of water and the volume again reduced to 5 ml.; a further 10 ml. of water is added, the volume reduced to 8 to 10 ml. and the procedure repeated until there is no further odour of acetic acid. (Care must be taken that phenetidin sulphate is not formed by excessive concentration of the solution). The cooled mixture is diluted to about 20 ml. and the caffeine extracted with chloroform. For phenacetin the solution of phenetidin sulphate is made slightly alkaline with sodium bicarbonate, 50 ml. of chloroform and 5 drops of acetic anhydride for every 0.1 g. of phenacetin believed to be present are added, the mixture shaken vigorously and the chloroform washed with water. The extraction is repeated with 2 further portions of chloroform, the chloroform evaporated, excess acetic anhydride removed by repeated evaporations with 1 ml. of chloroform, and the residue of reformed phenacetin weighed after drying in air or in a vacuum desiccator over lime.

Method for the Determination of Phenacetin and Caffeine in Tablets. The second report of the Commission Internationale des Spécialités includes an agreed method for the determination of phenacetin and caffeine in tablets in which the phenacetin and caffeine are extracted with chloroform and the phenacetin hydrolysed by dilute sulphuric acid to phenetidin which remains in solution as the sulphate. The solution is diluted with water and the caffeine extracted with chloroform, and the residue on evaporation of the chloroform is dried and weighed. The aqueous solution of phenetidin sulphate is treated with a slight excess of sodium bicarbonate and chloroform and acetic anhydride added. After shaking, the chloroform layer is drawn off, washed, and filtered, and the chloroformic extraction is repeated twice. The mixed chloroform solutions are then evaporated and the residue of phenacetin dried and weighed.—*Bull. Féd. int. Pharm.*, 1938, 85.

Tabellæ Acetophenetidini et Phenylis Salicylatis (N.F. VII). Contain 90 to 110% of the labelled amounts of acetophenetidin and phenyl salicylate, including all tolerances. Assayed for phenacetin by extracting with chloroform, removing the chloroform, hydrolysing the salol by heating with 2.5% sodium hydroxide for 15 minutes over a steam-bath, extracting the phenacetin from the cooled alkaline liquid with chloroform, filtering the combined chloroform extracts, removing the chloroform, drying and weighing. Assayed for salol by treating the alkaline liquid from the preceding assay as described under salol tablets.

PHENAZONUM

Phenazonum (B.P.). $C_{11}H_{12}ON_2 = 188.1$. M.p., 111° to 113°. Ash, not more than 0.1%. Antipyrina, U.S.P. XII, leaves not more than 0.15% of ash. Phényldiméthylpyrazolone, Fr. Cx. 1937, contains not less than 99% of the pure substance:—Dissolve

0.1 g. in 10 ml. water, add 1 g. potassium carbonate and 20 ml. N/10 iodine; after 1 hour add 1 ml. acetic acid then 10 ml. of chloroform and back titrate with N/10 sodium thiosulphate; 1 ml. N/10 iodine = 0.0094 g. phenazone.

Determination. It may be precipitated as $(C_{11}H_{11}N_3O)_2 \cdot H_2Fe(CN)_6$ from an acid solution by means of potassium ferrocyanide. A weighed quantity of the sample, containing 0.2 to 0.3 g. of phenazone, dissolved in 30 ml. of 0.8 N HCl is treated with 20 ml. of M/2 potassium ferrocyanide added slowly with stirring. Allow to stand for 30 minutes, collect in a Gooch crucible, wash with saturated aqueous phenazone hydroferrocyanide and dry at 105° to 110° . Add a correction of 0.005 g. for solubility. The precipitate contains 63.53% of phenazone. A volumetric method for determining the precipitate is also described. Amidopyrine does not interfere with either result.—I. M. Kolthoff, *J. Amer. pharm. Ass.*, 1933, 947.

0.2 g. of the antipyrine and 2 g. of sodium acetate are dissolved in 20 ml. of water in a stoppered flask and 30 ml. of N/10 iodine solution added. The flask and contents are allowed to stand with occasional shaking for 20 minutes. The precipitate is then dissolved by adding 10 ml. of chloroform and shaking, and the excess of iodine titrated with N/10 sodium thiosulphate solution. The amount of iodine reacting with the reagents is determined by repeating the process, omitting the antipyrine, or preferably by using only 10 ml. of N/10 iodine for the blank determination. An allowance is made for the iodine which reacts with the reagents.—H. Brindle, *Quart. J. Pharm.*, 1934, 453.

An official method for the determination of mixtures of phenazone and caffeine is described in *Methods of Analysis (A.O.A.C.)*, 1940, 573).

To 10 to 15 ml. of solution containing about 0.1 to 0.2 g. of phenazone add sufficient hydrochloric acid to make the content of HCl 5%. Add 0.5 to 1.0 g. of potassium bromide and 1 drop of a 0.2% alcoholic solution of *p*-ethoxy-chrysoidine and titrate with N/10 or N/100 potassium bromate until the red colour disappears. Each ml. of N/100 potassium bromate is equivalent to 0.94055 g. of phenazone. Caffeine sodium benzoate, caffeine citrate, phenacetin, acetylsalicylic acid and glycerol do not interfere.—E. Schulek and J. Kovács, per *Chem. Abstr.*, 1940, 34, 7063.

Phenazoni Salicylas (B.P.C.). $C_{11}H_{12}ON_3 \cdot C_7H_6O_3 = 326.2$. Contains not less than 57% of phenazone, and not less than 42% of salicylic acid. M.p., 91° to 92° . Ash limit, 0.1%. Assayed for phenazone by extraction with chloroform from sodium hydroxide; the residue on evaporation responds to the identity tests for Phenazonum. Salicylic acid content is determined by titration in 60% alcohol solution with N/10 sodium hydroxide to phenol red.

Antipyrinum salicylicum, *P. Helv. V*, contains 42.0 to 42.3% of salicylic acid when a solution of 1 g. in 20 ml. of alcohol and 30 ml. of water is titrated with N/10 sodium hydroxide, using phenolphthalein as indicator.

Amidopyrina (B.P.). $C_{13}H_{17}ON_3 = 231.2$. M.p., 107° to 109° . Ash limit, 0.1%. Aminopyrina, *U.S.P. XII*, complies with a test for antipyrine, in which 0.1 g. should develop no more colour when heated to boiling with 0.1 g. of vanillin, 5 ml. of water and 2 ml. of sulphuric acid than a control omitting the aminopyrine.

An official method for the determination of amidopyrine is described in *Methods of Analysis (A.O.A.C.)*, 1940, 573). The amidopyrine, extracted with chloroform from a solution made alkaline with ammonia or sodium hydroxide solution, is dried and weighed. Melting point and identity tests are applied to the residue.

Detection of Phenazone in presence of Amidopyrine. Use is made of the reaction between phenazone and ammoniated mercury in warm aqueous solution: after cooling, potassium iodide is added to the filtrate and the solution titrated with 0.1N Iodine. Amidopyrin does not react under these conditions.—F. Monforte, per *Brit. chem. Phys. Abstr. B.*, 1938, 977.

Tabellæ Amidopyrinæ (N.F. VII). Contain 92.5 to 107.5% of the labelled amount of amidopyrine, including all tolerances. Assayed by extracting a weighed quantity of powdered tablets with N/1 hydrochloric acid, filtering and rendering alkaline with ammonia solution an aliquot of the filtrate, extracting with chloroform, washing the combined chloroform extracts with water, extracting the washings with a further portion of chloroform, filtering the combined chloroform extracts, removing the chloroform, drying and weighing the residue.

PHENOL

Phenol (B.P.). $C_6H_5O = 94.05$. Contains not less than 98% of the pure substance. Residue on volatilisation on a water-bath, not more than 0.05%. Assayed for bromine absorption by a modified Koppeschaar process (*vide infra*).

The following *British Standard Specifications* have been prepared by the British Standards Institution for different grades of phenol and carbolic acids. Each specification contains descriptions in detail of the tests which are applied and descriptions of the apparatus used.

B.S.S. No. 523—1933 relates to crystalline phenol and liquefied phenol or solutions of phenol.

B.S.S. No. 515A—1933 and *No. 515B—1933* refer to crude carbolic acids, 60's and 45's. Crude carbolic acid 60's contains not more than 15% of water, has a gravity not lower than 1.055 and shows not more than 6% of residue on distillation, whilst crude carbolic acid 45's contains not more than 12% of water, has a gravity not lower than 1.050 and shows also not more than 6% of residue on distillation.

Quantitative Estimation of Phenol, Koppeschaar Process. This depends upon converting it into tribromophenol, $C_6H_2Br_3OH$:—

Dissolve phenol, 1.5 g., in water sufficient to make 1000 ml. Place 25 ml. of the solution in a 200 ml. stoppered bottle, add 30 ml. of N/10 bromine solution (*Koppeschaar's Solution*) and shake repeatedly for half an hour; allow to stand 15 minutes, then add 5 ml. of 10% potassium iodide solution, shake well, add 1 ml. of chloroform and titrate excess of iodine with N/10 thiosulphate. Subtract the number of ml. required from thirty; the remainder equals the number of ml. of N/10 bromine used up. This multiplied by 4 gives the percentage of absolute phenol (i.e. 1 ml. N/10 Br = 0.001568 g. of phenol).

Koppeschaar's Bromine Solution is made as follows:—

Dissolve potassium bromate, 3.2 g., and potassium bromide, 50 g., in water, 900 ml. To standardise, place 20 ml. in a 250 ml. bottle with 75 ml. of water and 5 ml. of hydrochloric acid. Shake a few times, quickly introduce 5 ml. of 20% potassium iodide solution and titrate the iodine set free with N/10 sodium thiosulphate. Dilute the bromine solution so that equal volumes of it and the N/10 thiosulphate exactly correspond in the conditions of the test.—*cf. U.S.P. XII*, p. 749, and *B.P.*, p. 513.

Phenol Liquefactum (B.P.). Contains 78.5 to 81.5% *w/w* of phenol. The *B.P. Add. I* directs that Phenol Liquefactum be completely liquefied before use if congealed or if crystals have deposited through storing below 4°. The *U.S.P. XII* preparation contains not less than 88% *w/w* of C_6H_5OH ; b.p., not above 182°.

Trochiscus Phenolis. Assay. For the assay of phenol in preparations containing ingredients which react with bromine a known quantity of the preparation containing about 0.15 g. of phenol is placed in a flask with 125 ml. of water, acidified with hydrochloric acid, and 25 g. of anhydrous calcium chloride added. The mixture is distilled until about 100 ml. of distillate is collected. The volume of distillate is adjusted exactly to 100 ml. and the phenol determined in 30 to 40 ml. of the solution by the *B.P.* method. In the case of phenol lozenges, allowance should be made for loss of phenol during manufacture. The standard should be set on the percentage of phenol present and

not on the amount in each lozenge. The lozenges should be required to weigh not less than 1.10 and not more than 1.22 g., and contain not less than 1.75% of C_6H_5OH .—C. E. Corfield and L. M. Mundy, *Quart. J. Pharm.*, 1932, 504.

The following is an alternative process:—The lozenges are first weighed, and crushed. A convenient weight of the crushed material, usually about 3 to 4 g., is dissolved in water, and the solution adjusted to a volume of 100 ml. 25 ml. of this solution is placed in a 300 ml. flask, and diluted with water to a volume of 150 ml. The flask is fitted to a condenser, and the contents distilled until only about 5 ml. remain in the flask. An asbestos ring should be used to prevent overheating. Distillation may be rapid at first, but towards the end, caution is required to prevent overheating and possible charring of the residue. The distillate is collected in a 300 ml. stoppered bottle, and the temperature brought to about 20°. 30 ml. of N/10 iodine and 30 ml. of N/10 sodium carbonate are added, and the mixture allowed to stand for 5 minutes. The mixture is then acidified by the addition of 5 ml. of dilute sulphuric acid, and the excess iodine is titrated with N/10 sodium thiosulphate. Each millilitre of N/10 iodine is equivalent to 0.001567 g. of phenol.—C. A. Hill and A. D. Powell, *Quart. J. Pharm.*, 1934, 535.

Unguentum Phenolis. Assay. The phenol may be separated from the base in a form suitable for titration with bromine either by distillation from acid solution or by solution in N/1 sodium hydroxide and separation of the phenol solution by means of calcium chloride.—E. M. Smelt, *Quart. J. Pharm.*, 1932, 509.

Dissolve 0.5 g. in about 10 ml. of light petroleum, and extract with four 10 ml. portions of a solution of 7 ml. of hydrochloric acid and 33 ml. of water, shaking for two minutes on each occasion. Collect the extracts in a Wijs iodine flask, add 20 ml. of N/10 bromate-bromide, and complete the analysis in the usual way. Two analyses gave results of 99.6% and 100.8% of the theoretical amount of phenol.—R. M. Savage, *Quart. J. Pharm.*, 1939, 420.

Unguentum Phenolis, U.S.P. XII. is determined by titration, with N/10 bromine, of the liquid obtained by steam distillation. C_6H_5OH content, 1.8 to 2.2%.

Betanaphthol (B.P.). $C_{10}H_8O = 144.1$. M.p., 120° to 122°. Ash, not more than 0.05%. No violet colour should be produced when the precipitate produced by ferric chloride is heated.

Hexyl-Resorcinol (B.P.C.). $C_{12}H_{18}O_2 = 194.1$. M.p., not below 66°. Ash, not more than 0.1%. The U.S.P. XII substance, dried to constant weight over sulphuric acid, contains 98% of $C_{12}H_{18}O_2$.

A tentative method for the determination of hexyl-resorcinol is described in *Methods of Analysis (A.O.A.C., 1940, 609)*. Dissolve about 0.8 g., accurately weighed, in 10 ml. of methyl alcohol in a 150 ml. glass-stoppered flask. Add 30 ml. of N/10 bromide-bromate solution, and 5 ml. of hydrochloric acid. Stopper the flask and swirl under running cold water to cool to room temperature, and continue to shake for 5 minutes. Add 5 ml. of 20% potassium iodide solution, swirl gently, wash the stopper with water, add 1 ml. of chloroform, and titrate with N/10 sodium thiosulphate. Towards the end of the titration add starch paste. The end-point is reached when the blue colour does not return during 30 seconds vigorous shaking. 1 ml. of N/10 bromide-bromate = 0.00488 g. of hexyl-resorcinol.

Pyrogallol (B.P.C. Supp. IV). $C_6H_6O_3 = 126.0$. M.p., 129° to 135°. Ash limit, 0.1%. The aqueous solution is clear, not more than slightly yellow, and neutral to methyl orange. The N.F. VII substance melts between 130° and 133°, and leaves not more than 0.1% of ash.

Resorcinol (B.P.). $C_6H_6O_2 = 110.0$. M.p., 110° to 111°. Ash limit, 0.05%. A 5% solution produces no precipitate with lead acetate solution, indicating absence of catechol. Resorcinol, U.S.P. XII, after drying to constant weight over sulphuric acid,

contains not less than 99.5% of $C_6H_4(OH)_2$. Assayed by bromine absorption during 1 minute, interaction with potassium iodide and titration with N/10 sodium thiosulphate.

Estimation of resorcinol in Resorcinol Ointment, *B.P.C.*, and Compound Resorcin Ointment, *B.P.C.*, by bromate titration.—Garratt, *Quart. J. Pharm.*, 1935, 472.

Sodii Phenolsulphonas (*B.P.C.*). $C_6H_5O_4SNa, 2H_2O = 232.1$. Assayed on its power of bromine absorption it contains from 99% to the equivalent of 103% of the pure substance.

Zinci Phenolsulfonates (*N.F. VII*). Contains 73.7 to 77.4% of anhydrous zinc phenolsulfonate, corresponding to not less than 99.5% of the octahydrate; determined by precipitation as carbonate and ignition to oxide.

An official method for the determination of phenolsulphonates is described in *Methods of Analysis* (*A.O.A.C.*, 1940, 623).

Dinitrophenol. 2:4-Dinitrophenol may be detected by the following tests. Add sodium hydroxide solution to the suspected sample and extract with chloroform. Allow the chloroform to evaporate and to the residue add 2 ml. of 10% sulphuric acid and 0.2 g. of powdered zinc; a pink colour developing within 10 minutes indicates the presence of dinitrophenol. Confirm by adding 10 drops of 1% sodium nitrite solution, allowing to stand in the dark for 5 minutes and adding 10 ml. of ether; a pink or violet colour should develop in the ethereal layer.—J. S. Shupe, *J. Ass. off. Agric. Chem., Wash.*, 1935, 464.

Official methods for the determination of dinitrophenol or its sodium compound in the absence and presence of interfering substances are described in *Methods of Analysis* (*A.O.A.C.*, 1940, 608).

Trinitrophenol (*B.P.*). $C_6H_3O_7N_3 = 229.0$. Contains not less than 99% of $C_6H_3O_7N_3$. M.p., 121° to 123° (precautions being taken). Residue on extraction with benzene at 50° , not more than 0.1%. Determined by titration with sodium hydroxide to phenolphthalein. The *U.S.P. XII* allows 0.2% of matter insoluble in benzene at ordinary temperature and dried at 100° . Acidum picricum, *P. Helv. V*, is assayed by dissolving 0.29 g. in 30 ml. of water and adding 10 ml. of a solution containing 0.36% of potassium iodate and 1.5% of potassium iodide. When the potassium picrate formed has dissolved, titrate with N/10 sodium thiosulphate, using starch as indicator towards the end of the titration and making a blank on the iodate-iodide solution. 1 ml. of N/10 $Na_2S_2O_3, 5H_2O$ is equivalent to 0.022905 g. of $C_6H_3O_7N_3$.

Estimation of Picrates. The picrate is dissolved in water and titrated with 0.001N methylene blue solution. The methylene blue picrate, formed during the titration, is extracted with chloroform from the aqueous layer. Since methylene blue is practically unextractable with chloroform, the end-point is detected by the colour of the aqueous layer, the titration liquid acting as indicator. The method is also used for the estimation of picrolonates.—A. Bolliger, *Analyst*, 1939, 416.

Carbasus Trinitrophenolis (*B.P.C.*). By titration of the gauze shaken with water a content of from 1.5 to 2.5% *w/w* of $C_6H_3O_7N_3$ should be indicated.

"T.N.T." *Trinitrotoluene*. *Syn.* Trotyl. $C_6H_5CH_3(NO_2)_3 = 227.1$. Commercially it is seen as crumbs or granules of fine plate crystals. Melting about 80° . It is obtained by nitrating toluene. Soluble in acetone, ether, benzene, and xylol.

"T.N.T." is stable and does not attack metals. When absorbed, mainly through the skin, it is liable to cause dermatitis, digestive troubles, cyanosis and jaundice.

Amatol is T.N.T. mixed with 40 to 60% of ammonium nitrate. Mixed with 20% it is AMMONAL.

For further information on T.N.T. and other explosives see "High Explosives,"—E. de W. S. Colver, 1918; "T.N.T. and Mono- and Di-Nitrotoluene, their manufacture and properties."—G. Carlton Smith, 1918; and "Explosives," by E. de Barry Barnett, 1919.

Seven cases of T.N.T. jaundice in an ordnance filling factory, with two deaths, the jaundice appearing within six months of beginning work. The associated symptoms were nausea, anorexia and epigastric discomfort. Treatment was by glucose, insulin and vitamin C. Prophylactic measures include protection of the skin, washing, adequate ventilation, a healthy life and full diet.—R. M. Evans, *Lancet*, ii/1941, 552.

The T.N.T. health hazard.—H. M. Roberts, *Brit. med. J.*, ii/1941, 647.

Clinical manifestations of tetryl and trinitrotoluene.—J. Hilton and C. N. Swanson, *Brit. med. J.*, ii/1941, 509.

Trinitro-butyl-toluene, $C_8HCH_3C_6H_2(NO_2)_3$, is synthetic musk or tonquinol.

In artificial musks, it is possible to replace the nitro groups by CHO, OCH₃, COCH₃, halogens and CN, without altering the odour, but the tertiary butyl group, or the presence of tertiary carbon, is essential.—*Per um. essent. Oil Rec.*, 1924, 360.

PHENOLPHTHALEINUM

Phenolphthaleinum (*B.P. Add. I*). $C_{20}H_{14}O_4 = 318.1$. M.p., not below 258°. Sulphated ash, not more than 0.05%. The *U.S.P. XII* requires the m.p. to be not below 258°; ash, not more than 0.1%.

Determination in Tablets. A method for determination of phenolphthalein in tablets is given in the *N.F. VII*. A portion of powdered tablets is extracted with boiling alcohol, cooled, adjusted to volume, filtered, and an aliquot part evaporated to dryness. Four or more drops of potassium hydroxide solution and 5 ml. of water are added and the phenolphthalein dissolved completely. Maintaining the temperature at 0° to 5°, 4.5 ml. of an iodine solution (7 g. of iodine in 10 ml. of saturated potassium iodide solution, water to 60 ml. and potassium hydroxide solution to discharge the colour) is added, followed by hydrochloric acid to complete precipitation. The precipitate is dissolved in potassium hydroxide solution, the precipitation and resolution repeated twice and then sodium sulphite solution (15%) added and if necessary filtered. After acidifying with hydrochloric acid and heating on a water-bath for 30 minutes, the precipitate is collected, washed with cold water and petroleum ether and dried at 130° to 140°. 1 g. of residue = 0.3871 g. of phenolphthalein.

Determination in tablets may be accomplished by extraction in a Soxhlet apparatus with acetone, from which the phenolphthalein is removed by shaking with a known volume of N/10 sodium hydroxide. The latter is filtered, an aliquot portion is acidified and the phenolphthalein extracted with ether. The ethereal solution is washed with water and evaporated, and the residue dried and weighed.—G. Thomas, *J. Pharm. Belg.*, 1939, 21, 361.

An official quantitative ether-extraction method for the determination of phenolphthalein in tablets and a tentative method for chocolate preparations similar to the above *N.F. VII* process are described in *Methods of Analysis* (*A.O.A.C.*, 1940, 611). A tentative method for the determination of acetylsalicylic acid and phenolphthalein tablets is also described (*ibid.*, 571).

The second report of the Commission Internationale des Spécialités includes an agreed method for the determination of phenolphthalein in tablets in which the phenolphthalein extracted with hot alcohol 95% is dissolved in a little 50% potassium hydroxide solution and converted into tetraiodophenolphthalein by adding N/10 iodine solution in the presence of ice, the excess of iodine being titrated with sodium thiosulphate solution.—*Bull. Féd. int. Pharm.*, 1938, 87.

Determination in Paraffin Emulsions. A sufficient quantity of emulsion to yield 0.05 to 0.1 g. of phenolphthalein is accurately weighed into a glass-stoppered Erlenmeyer flask, a mixture of 75 ml. of ether and 25 ml. of alcohol is added, and the mixture is shaken vigorously and then set aside for 30 minutes.

It is then filtered into a separating funnel and the precipitated agar is washed with successive portions of the same ether-alcohol solvent mixture. The agar is redissolved in about 5 ml. of water and again precipitated with the solvent mixture, the liquid and washings being filtered into the separating funnel containing the filtrate previously obtained. The agar may be tested for phenolphthalein by addition of alkali to an aqueous solution of a small portion and is discarded if no phenolphthalein is present. The phenolphthalein is completely extracted from the solvent mixture by shaking with successive 10 ml. portions of N/25 sodium hydroxide, and precipitated by slowly adding N/10 sulphuric acid in slight excess. It is then extracted from the acid liquid by means of ether, re-transferred to N/25 sodium hydroxide, and again precipitated by means of a very small excess of N/10 acid. The liquid is allowed to stand overnight to allow large crystals to form and the phenolphthalein is collected on a tared Gooch crucible, washed with 4 portions, each of 5 ml. of water, dried at 100° and weighed. The filtrate and washings are transferred to a 250 ml. graduated flask, the beaker in which the phenolphthalein was precipitated is rinsed out with the N/25 alkali which was added to that in the flask, the contents of which are made up to volume. The phenolphthalein remaining in solution is now determined colorimetrically using as standard a solution of 0.03 g. in 250 ml. of N/25 sodium hydroxide, the weight so obtained being added to that previously obtained.—C. F. Bickford and R. E. Schoetzw, *J. Amer. pharm. Ass.*, 1936, 1128.

Fluoresceinum Solubile (B.P.). $C_{20}H_{10}O_5Na_2 = 376.1$. Soluble fluorescein loses at 105° not more than 5%.

Iodophthaleinum (B.P.). $C_{20}H_8O_4I_4Na_2 \cdot 3H_2O = 919.8$. Contains not less than 85% of phthalein, and the separated phthalein contains 61 to 62% of I. Assayed by precipitation of the phthalein from aqueous solution with dilute hydrochloric acid, washing with a mixture of equal volumes of acid and water, and drying at 110°; by fusion of a portion of the residue with sodium carbonate, extraction with hydrochloric acid and water, and titration with M/20 potassium iodate the iodine content is obtained. Iodophthaleinum Sodicum, *U.S.P. XII*, contains not less than 85% of tetraiodophenolphthalein and this contains 60 to 63% of I. The tetraiodophthalein obtained in the assay is tested for proportion of iodine by dissolving on the steam-bath in sodium hydroxide solution (5%) and, after the addition of potassium permanganate solution (1 in 15), heating on the steam-bath for three-quarters of an hour. After cooling, the mixture is diluted with water, diluted sulphuric acid and sodium bisulphite solution (20%) added, followed by potassium permanganate solution till a faint yellow colour appears and the colour finally discharged with sodium bisulphite solution. After addition of glacial acetic acid and then ammonium carbonate the mixture is titrated in diffuse light with N/10 silver nitrate using diiodofluorescein as indicator. The *Fr. Cx.* 1937 determines iodophthalein similarly; it should contain not less than 85%; iodine content not less than 52% determined by the process of the *Fr. Cx.* 1937 described under Thymol Iodide.

The use of this compound as a diagnostic test for cholecystic disease is described on p. 1040.

Assay. The following assay is recommended by the Sub-Committee on Synthetic Chemicals of the Committee on Pharmaceutical Chemistry:—Mix about 0.3 g., accurately weighed, of the phthalein, obtained in the assay for phthalein, with 2 g. of anhydrous sodium carbonate; place in a small crucible, and then fill the crucible completely with anhydrous sodium carbonate well

pressed down; invert the crucible and contents in a larger crucible, and add sufficient anhydrous sodium carbonate to seal the junction of the two crucibles. Heat rapidly and strongly over a Bunsen flame, and continue the heating for twenty minutes; allow to cool, and dissolve the residue in 100 ml. of hot water; filter, and wash the filter with a little water. To the cooled solution add hydrochloric acid until effervescence ceases, then add an additional 10 ml. of hydrochloric acid and 10 ml. of solution of potassium cyanide and titrate with M/20 potassium iodate until the dark brown solution which is formed becomes light brown, then add 5 ml. of mucilage of starch and continue the titration until the blue colour disappears. Each ml. of M/20 potassium iodate is equivalent to 0.01269 g. of I.—(*British Pharmacopœia Commission Report*, No. 12, May 1939.)

Sulfobromophthaleinum Sodicum (U.S.P. XII). $C_{20}H_8Br_4O_{10}S_2Na_2 = 838.04$. Loses at 100° not more than 5%. A test for sensitivity is included; 0.2 ml. of 0.1% solution diluted to 50 ml. with freshly boiled and cooled distilled water produces a strong violet colour upon addition of 0.2 ml. of N/50 sodium hydroxide, and the colour is discharged upon adding 0.2 ml. of N/50 sulphuric acid.

Phenol-Rubrum (B.P.C.). $C_{19}H_{14}O_5S = 345.2$. Phenol red loses at 110° not more than 1%. Sulphated ash, not more than 0.2%. The U.S.P. XII limit of moisture in Phenolsulfophthaleinum is the same, and the ash not more than 0.2%; a test for sensitiveness and a limit of matter insoluble in 2.5% sodium bicarbonate solution, dried at 110° , of not more than 0.2% are included.

For the use of phenol red as a renal function test see p. 663.

PHYSOSTIGMINA

Physostigminæ Salicylas (B.P.). $C_{15}H_{21}O_2N_3, C_7H_6O_3 = 413.2$. M.p. of the dry substance, 185° to 187° . Loses, when dried at 100° , not more than 1%; ash, not more than 0.1%. 0.1 g. complies with a limit test for readily carbonisable substances. The U.S.P. XII substance contains not more than 2% of moisture and complies with a test for sulphate.

Physostigminæ Sulphas (B.P.C.). $(C_{15}H_{21}O_2N_3)_2, H_2SO_4 = 648.5$. M.p., after drying at 100° , about 145° . When dried at 100° , loses not more than 1%. Ash, not more than 0.1%. Complies with tests for readily carbonisable substances and salicylate.

Neostigminæ Bromidum (U.S.P. XII). $C_{12}H_{19}BrN_2O_2 = 303.2$. Loses not more than 2% at 100° and then contains not less than 98% of $C_{12}H_{19}BrN_2O_2$. M.p. with decomposition, about 167° ; ash, not more than 0.15%. Assayed by hydrolysis with sodium hydroxide solution and distillation of the volatile amine into excess N/10 sulphuric acid followed by back titration of the excess acid, using methyl red indicator.

Tabellæ Neostigminæ Bromidi (U.S.P. XII). Contain 93 to 107% of the labelled amount of $C_{12}H_{19}N_2O_2Br$, including all tolerances. Assayed by macerating a weighed quantity of powdered tablets with 70% alcohol containing 1% of dilute hydrochloric acid, decanting through a filter and extracting the residue with two further portions of alcohol, removing most of the alcohol, transferring the residual solution to a Kjeldahl flask, adding water and sodium hydroxide solution and distilling into excess N/10 sulphuric acid, finally titrating the excess acid with N/10 sodium hydroxide, using methyl red indicator.

Neostigminæ Methylsulphas (*U.S.P. XII*). $C_{15}H_{22}N_2O_6S = 334.4$. Assayed by the *U.S.P. XII* method for neostigmine bromide and complies with the same standard. Loss at 100° , not more than 1%; m.p., 142° to 145° . (Neostigmine is known in this country under the trade name of Prostigmin—see Vol. I, p. 821.)

PILOCARPINA

Pilocarpinæ Hydrochloridum (*B.P.C.*). $C_{11}H_{16}O_2N_2.HCl = 244.6$. M.p., 204° to 205° , after drying to constant weight at 100° . Specific rotation, determined on a 10% w/v aqueous solution, $+90^\circ$ to $+92^\circ$. Ash, not more than 0.1%. Complies with tests for foreign alkaloids.

An official method for the determination of pilocarpine hydrochloride in tablets is described in *Methods of Analysis* (A.O.A.C., 1940, 588). The pilocarpine, extracted with chloroform from ammoniacal solution, is dissolved in an excess of standard sulphuric acid and back-titrated with standard sodium hydroxide, using methyl red as indicator.

Pilocarpinæ Nitras (*B.P.*). $C_{11}H_{16}O_2N_2.HNO_3 = 271.2$. M.p., 174° to 178° . Specific rotation of the 10% w/v aqueous solution, $+77^\circ$ to $+83^\circ$. Ash, not more than 0.1%. Complies with tests for certain other alkaloids. The *U.S.P. XII* requires the ash from 0.2 g. to be negligible, and the salt must comply with a test for various foreign alkaloids; 0.1 g. complies with a test for carbonisable substances.

A colorimetric method for the determination of pilocarpine in hypodermic tablets and injections, depending upon Shupe's modification of Helch's identity test, is described. Tables are given relating the value of the blue component of the colour obtained to the alkaloidal content.—N. L. Allport and N. R. Jones, *Quart. J. Pharm.*, 1942, 247.

Jaborandi (*B.P.C.*). Consists of the dried leaflets of *Pilocarpus microphyllus* Stapf, and contains not more than 5% of stalks, stems and other foreign organic matter.

P. microphyllus is largely used in making pilocarpine and was official in *U.S.P. IX* if yielding not less than 0.6% of alkaloids.

PIPER NIGRUM

Piper Nigrum (*B.P.C.*). Contains not more than 2% of foreign organic matter. Ash, not more than 6%. Acid-insoluble ash, not more than 1%.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined black pepper as the dried immature berry of *Piper nigrum* L., containing not less than 6.75% of non-volatile ether extract, not less than 30% of starch, not more than 7% of total ash and not more than 1.5% of ash insoluble in hydrochloric acid. **Ground black pepper**: the product made by grinding the entire berry of *Piper nigrum* L., containing the several parts of the berry in their normal proportions. **Long pepper**: the dried fruit of *Piper longum* L. **White pepper**: the dried mature berry of *Piper nigrum* L. less the outer, or outer and inner, coatings: containing not less than 7% of non-volatile ether extract, not less than 52% of starch, not more than 5% of crude fibre, not more than 3.5% of total ash, and not more than 0.3% of ash insoluble in hydrochloric acid.—S. R. A., F.D., No. 2, Rev. 5, Nov. 1936.

Cubeba (*B.P.C.*). Should contain not more than 7% of shrivelled immature fruits, rachis and stems, and not more than 2% of foreign organic matter. Ash limit, 8%. *Cubeba, N.F. VII*, should yield not less than 13% *v/w* of volatile oil; shrivelled fruits or stems, not more than 5%; foreign organic matter, not more than 2%; acid-insoluble ash, not more than 2%.

Genuine cubebes yield 6.44 to 8.47% of resin and 12.5 to 20% of essential oil. Adulteration can be detected by means of the physical characters of the oil. —J. F. Clevenger, *J. Ass. off. agric. Chem., Wash.*, 1937, 140.

Oleum Cubebæ (*B.P.C.*). Sp. gr., 0.910 to 0.930; α_D , -20° to -35° ; n_{D20° , 1.480 to 1.502. Not less than 60% distils between 250° and 280° .

PITUITARIUM

Pituitary (posterior lobe) Extract. This extract is controlled by the Therapeutic Substances Act 1925, and is official in the *B.P.* and as *Injectio Pituitarii Posterioris* in the *U.S.P. XII*.

Its potency can be determined by its stimulant action on the isolated uterus of the guinea-pig, which is known as its oxytocic property, by its pressor action on the blood pressure of the spinal cat, and also by its antidiuretic effect on rats. An international standard has been adopted consisting of a quantity of dry acetone-extracted posterior lobe material which is kept in the National Institute for Medical Research, Hampstead. The unit is the amount of activity present in 0.5 mg. of the standard powder.

Oxytocic Potency. The determination of the action on the uterus is made by excising one horn of the uterus of a virgin guinea-pig and suspending it in a bath of Ringer's solution which is oxygenated and maintained at 37° . The muscle is very thin and, when pituitary extract is added to the bath, quickly responds by contraction. The extent of the contraction is proportional to the dose, hence the potency of an unknown solution can be found by comparing the contraction which a given amount of it produces with the contraction produced by a given amount of the standard extract. In practice, difficulties arise because the muscle of the horn changes in sensitiveness and wrong conclusions may easily be drawn respecting the potency of an unknown solution. The test usually takes one or two days to complete.

Pressor Activity. The determination is made on the blood pressure of a spinal cat, prepared as described under Adrenaline (*q.v.*, p. 55). An intravenous injection of pituitary extract causes a rise of blood pressure not so rapid as that produced by adrenaline but lasting much longer. The height of the rise is proportional to the dose and an unknown preparation is examined to see what amount produces the same rise as that produced by a given amount of the standard extract. The test takes much time, as successive doses must be separated by an interval of 1 hour; this is necessary because successive injections of the same dose at shorter intervals produce a diminishing response.

Antidiuretic Activity. A reliable method of determining activity which is economical in skilled labour depends on the antidiuretic effect which may be observed in rats. If a group of four rats, kept without food overnight, is given water by stomach tube, in a dose of 5 ml. per 100 g. body weight, then a diuresis occurs which reaches a maximum in 60 to 90 minutes. If a dose of pituitary extract be given at the time the water is administered, the excretion of water is delayed and the maximum diuresis may not occur until 130 or 190 minutes according to the dose. To compare an unknown extract with the standard, sixteen rats receive water and eight of these are injected with standard extract and eight with the unknown extract. The time of maximum diuresis is determined for each group of eight rats. Two days later the experiment is repeated, reversing the groups, so that the eight rats which previously received the standard now receive the unknown and *vice versa*. The antidiuretic effect of the standard and of the unknown extract is now known for all of the sixteen rats. From these measurements the potency of the unknown extract can be expressed in terms of that of the standard by using a predetermined curve relating antidiuretic effect to dose. The antidiuretic potency of different commercial extracts expressed in units is almost always the same as the oxytocic potency expressed in units.

Gonadotrophic Hormone. The following assay methods are available. (1) *Increase in weight of seminal vesicles:* This is applicable to preparations of the gonadotropin in the urine of pregnant women and of that in pregnant mare's serum. It is completely objective; the sensitivity is moderate; and the process is simple. (2) *Increase in weight of ovaries:* Applicable to preparations of gonadotropins from all three sources and is completely objective. The sensitivity varies with the gonadotropin concerned, being low for that of pregnant mare's serum but higher with larger doses, and moderate for anterior pituitary gonadotropin. (3) *Increase in weight of uteri:* Applicable to all three types, is completely objective and about as easy as the previous ones. The sensitivity is great, a six-fold increase in weight being obtained on either pregnancy urine or pregnant mare's serum preparations, with doses which will only double the weight of the seminal vessels and hardly affect the ovarian weight at all. (4) *Vaginal cornification:* This method is the simplest and is applicable to all three types. It is reasonably objective provided one sets as his standard a full oestrus smear, i.e., the complete disappearance of leucocytes and their replacement by epithelial cells. The sensitivity is great and appears to parallel rather closely the uterine weight method. (5) *Luteinisation:* This method is unsatisfactory in practically every respect. Unless microscopic sections are prepared which takes time and labour, the degree of luteinisation is difficult to determine; macroscopic examination fails on the score of objectivity. The method is insensitive and individual variation is still rather great.

Of these methods vaginal cornification is simplest and reasonably objective with practice. Since both uterine weight and vaginal oestrus can be determined simultaneously, i.e., on the same animals, a combination of these two methods might be employed. It must be remembered, however, that both responses are also produced by oestrogens, and the absence of the latter from the material being assayed must be assured.—R. G. Gustavson and F. E. D'Amour (Council on Pharmacy and Chemistry, A.M.A.), *J. Amer. med. Ass.*, ii/1941, 188.

The interpretation of assays for gonadotropin in menstruating women is not, as yet, clear of confusing elements, though they are of some value in regard to non-pregnant women with amenorrhœa. It is well-established that in the complete absence of ovarian function in adult women there is an increased excretion of gonadotropin. Thus, in amenorrhœa due to ovarian failure, spontaneous menopause or surgical castration increased amounts of gonadotropin

are present in blood and urine. The increase in urinary gonadotropin may be detected within as little as three days following ovariectomy. Even in patients without ovaries, however, the excretion fluctuates significantly, necessitating repeated tests at times before conclusions can be drawn as to whether or not any particular patient has ovarian failure. Such tests are of some value, therefore, in determining whether the pituitary or the ovary is at fault in cases of amenorrhœa. If the absence of menstruation is due to failure of the pituitary little or no gonadotropin will be excreted; if the ovaries are at fault this substance will be found in most cases on thorough investigation.—S. C. Freed, *J. Amer. med. Ass.*, ii/1941, 104.

The luteinising hormone can be estimated by the method of Janssen and Loeser, *Arch. exp. Path. Pharmac.*, 1930, 151, 188, in which infantile rats are injected and the ovaries are examined for corpora lutea. Hill, Parkes and White (*J. Physiol.*, 1934, 81, 335) have proposed a method of estimating the ovulation-producing substance by means of this property of causing ovulation in the oestrous rabbit. The method depends on the fact that ovulation never occurs spontaneously in the rabbit but only after copulation or after injection with the hormone. In the adult female non-pregnant rabbit carefully segregated from the male, the ovaries always contain eggs waiting to be discharged. Full-grown female rabbits (3 to 4 kg.) may be used, which, when received from the dealer, must be kept for 5 weeks in order that pregnant animals may complete pregnancy and regain the oestrous condition. The extract to be tested is then injected into a batch of twenty rabbits, the dose being administered intravenously. On the following day the ovaries are examined by making incisions into the abdominal cavity under ether anaesthesia, using full aseptic precautions. The number of animals which have ovulated is thus determined. When this number is expressed as a percentage of the number of animals injected, the amount of extract containing 1 unit, which is the amount producing a 50% response, may be calculated from a curve relating dose to percentage of animals responding, which has been determined.

Thyrotrophic Hormone. The amount excreted is apparently increased following thyroidectomy. The use of thyrotrophic hormone assays in the clinic has been somewhat limited owing to the variability of the results of different investigators. In myxœdema an increased elimination has been observed. The blood of such patients is also claimed to be rich in this substance, while little, if any, is found in the opposite state of hyperthyroidism. With regard to acromegaly there is a difference of opinion as to whether there is increased excretion, while in Simmonds' disease it is claimed to be below normal. Practical use of this test is not very great, since considerable technical facilities are required. A further complication has arisen, since recent work indicates that the thyrotrophic principle may be separated into two factors, one which stimulates the growth of the thyroid gland and one which stimulates the secretion of the thyroid hormone.—S. C. Freed (Council on Pharmacy and Chemistry, A.M.A.), *J. Amer. med. Ass.*, ii/1941, 104.

PIX LIQUIDA

Pix Liquida (B.P.). Wood tar, known in commerce as Stockholm tar. *Pix Pini, U.S.P. XII*, leaves not more than 0.3% of ash. *Goudron Végétal, Fr. Cx.* 1937, by distillation with xylene, should yield not more than 2.5% of water, and loses not more than 18 to 19% at 100°. Acidity (expressed as acetic acid), not more than 0.1%. Saponification value, 115 to 120. Viscosity, 37.7 at 40° (Engler), 280° to 305° (Stokes).

Oleum Picis Rectificatum (U.S.P. XII). Sp. gr. at 25°, 0.960 to 0.990.

Pix Carbonis (B.P.C.). Ash, not more than 2%. Water shaken with it gives an alkaline reaction.

Pix Carbonis Præparata (B.P.). Coal tar heated at 50° for 1 hour.

Oleum Cadinum (B.P.). Sp. gr., 0.975 to 1.010; n_{D20}° , 1.510 to 1.530. The presence of pine tar oil is excluded by the absence of green colour in the resin test when a petroleum extract is shaken with copper acetate solution. Pix Juniperi, *U.S.P. XII*, complies with a similar test for rosin or rosin oils, but with addition of ether to the petroleum ether layer after separation, and has a sp. gr. at 25° of 0.950 to 1.055. The *Fr. Cx.* 1937 requires Goudron de Cade to comply with limits for distillation—not more than 2% below 150°, not less than 50% between 150° and 200°, not less than 30% between 200° and 250° and 18% above 250°. A minimum limit of substances insoluble in caustic soda solution of 60% is required, and the cadinine hydrochloride separated from this should melt at about 118°; a 10% solution of the essence in acetic ether should have rotation not less than -4° in a decimetre tube.

Oleum Rusci (B.P.C.). Sp. gr., 0.920 to 0.955. Unsaponifiable matter, not less than 70%. A test for absence of fir tar is described. Oleum Betulae Empyreumaticum Rectificatum, *N.F. VII*, has a sp. gr. at 25° of 0.886 to 0.950 and complies with a test for distinction from oil of cade.

PLUMBUM

Plumbi Acetas (B.P. Add. I). $C_4H_5O_4Pb \cdot 3H_2O = 379.3$. Contains from 99.5% to the equivalent of 104.5% of the pure substance. Assayed by precipitation as oxalate and titration with N/10 potassium permanganate. Plumbi Acetas, *U.S.P. XII*, contains 85.31 to 89.57% of the anhydrous salt, corresponding to not less than 99.5% of the trihydrate; in assaying, the lead is precipitated by addition of excess N/10 potassium dichromate, and, after filtering, the excess dichromate is determined in the filtrate iodometrically.

Liquor Plumbi Subacetatis Fortis (B.P.). Assayed for total lead by precipitation with oxalic acid, decomposition of the washed precipitate with sulphuric acid and titration with N/10 potassium permanganate, it contains 19 to 21.5% *w/w*. Alkalinity corresponding to 10.2 to 11.6% *w/w* of PbO , determined by addition of N/1 sulphuric acid, adjusting to volume, and titration of an aliquot of the clear liquid with N/1 sodium hydroxide, using phenolphthalein indicator.

Plumbi Carbonas (B.P.C.). Assayed for lead content by precipitation of the acetic acid solution with ammonium oxalate and titration of the precipitate, decomposed by sulphuric acid, with N/10 potassium permanganate, not less than 79% of Pb should be indicated. Matter insoluble in diluted nitric acid, not more than 1%.

Plumbi Iodidum (B.P.C. Supp. IV). $PbI_2 = 461.1$. Assayed for halogen content by addition of excess silver nitrate and nitric acid to a solution in sodium hydroxide solution and back titration

with N/10 ammonium thiocyanate; after allowance for the chloride in the sodium hydroxide solution, a purity of not less than 95% is required.

Plumbi Monoxidum (B.P.). $PbO = 223.2$. Loses not more than 4% on ignition and then contains not less than 99% of PbO . Assayed by precipitation as oxalate and titration with N/10 potassium permanganate. **Plumbi Monoxidum, N.F. VII,** is assayed by precipitation with excess N/10 oxalic acid, filtration and titration of the excess acid in an aliquot part with N/10 potassium permanganate; a purity of the freshly ignited substance of not less than 97% is required. Loss on ignition, not more than 4%.

The B.P. methods for the assay of lead preparations are inaccurate. Alternative methods of assay, which combine sufficient accuracy with easy and rapid manipulation, are suggested, and also assay processes for the suppository and plaster.—S. Wetherell, *Quart. J. Pharm.*, 1935, 453.

Determination of Lead in Organic Material. Lead in organic materials may be determined by using diphenylthiocarbazon (syn. dithizone), $C_6H_5 \cdot NH \cdot NH \cdot CS \cdot N : N \cdot C_6H_5$. The reagent is used as a 0.1% solution in chloroform; the solution should be freshly prepared. The organic material is oxidised by heating with sulphuric and nitric acids or with sulphuric acid and hydrogen peroxide and the excess oxidising agent is removed by evaporation. The cooled residue is diluted and 2 g. of citric acid is dissolved in the solution to prevent precipitation of iron. About 1 ml. of 10% potassium cyanide solution is added and the mixture made alkaline with ammonia. The lead is then extracted by shaking with three successive portions of the reagent (10, 5 and 5 ml.), each extract being washed once with 10 ml. of water. The mixed extracts are evaporated to dryness and the organic matter is destroyed by heating with 1 ml. of sulphuric acid until white fumes are evolved, then adding a few drops of nitric acid and continuing to heat until the liquid is almost colourless. The residue is dissolved in water and the lead determined colorimetrically in the usual manner by comparing the colour produced on adding sodium sulphide in the presence of ammonium acetate with that obtained with known amounts of lead.

Separation of lead from other metals, except bismuth, by extraction with diphenylthiocarbazon in chloroform, in the presence of potassium cyanide.—Allport and Skrimshire, *Analyst*, 1932, 440; also Roche Lynch, Slater and Osler, *Analyst*, 1934, 787. In presence of bismuth.—Hamence, *Analyst*, 1933, 46; 1934, 274.

LEAD POISONING

Lead Paint Regulations 1927 (S.R. & O., 1927, No. 847), under Lead Paint (Protection against Poisoning) Act 1926 (16 and 17 Geo. 5, c. 37).

Lead paint for buildings must be in paste form or paint ready for use (but red lead may be had raw or dry for stopping or filling). Must not be used in form of spray in interiors. Surfaces other than iron or steel must not be rubbed down or scraped by dry process, except if the surface contains no lead.

Spraying Paint or Lacquer. The practice of spraying paints or lacquer containing over 1% of lead should be discontinued, or carried out only where adequate air movement is provided. Similarly, the amount of benzol used in lacquers should be limited to 0.5%. Definite silicosis hazard from spraying of vitreous enamels.—*Lancet*, ii/1928, 177.

An improved method for determining the lead content of blood and excreta.—S. L. Tompsett and A. B. Anderson, *Lancet*, i/1939, 599.

A photometric method based upon the dithizone "mixed colour" method of Clifford and Wichman is proposed, which includes a three-stage extraction process, whereby the lead is obtained in a high state of purity.—D. M. Hubbard, *Industr. Engng Chem. (anal. Edn.)*, 1937, 29, 493.

The error in the above process decreases as the initial volume of material used decreases. This was found by comparison with the spectrographic method which also gives more accurate results with amounts of lead less than 1 microgramme. Both methods give good results for lead in fæces and mixed food

samples.—J. Cholak, D. M. Hubbard, R. R. McNary, and R. V. Storey, *Industr. Engng Chem. (anal. Edn.)*, 1937, 29, 488.

The determination of traces of lead in bone and biological materials can be made without ashing the organic material by the use of diphenylthiocarbazon to extract the lead. Fresh bone contains from 14.5 to 146 parts per million of lead; teeth from five normal persons contained 42.5 to 247.5 parts per million.—G. Roche Lynch, R. H. Slater and T. G. Osler, *Analyst*, 1934, 787.

Lead Tetraethyl is a liquid boiling at 150° with decomposition. It is manufactured by treating lead tetrachloride with methyl magnesium iodide. The products of combustion are: (1) with excess air—chiefly carbon dioxide and lead oxide, (2) with deficiency of air (e.g., in engine cylinder)—chiefly carbon monoxide and lead. It is not very volatile at ordinary temperatures.—*Pharm. J.*, i/1928, 268.

Lead poisoning due to the manufacture, etc., of tetraethyl lead. The condition bears little resemblance to clinical types of lead poisoning. The compound is not immediately corrosive, but causes necrosis after lengthy exposure. If allowed to remain on the skin for half an hour no sensation is produced but desquamation occurs after a day or two. Poisoning results from a combination of skin absorption and inhalation of vapour. The inhalation of dust has also caused illness.—R. A. Kehoe, *J. Amer. med. Ass.*, ii/1925, 108.

Determination in motor fuels of lead tetraethyl.—*Analyst*, 1926, 104.

Interim Report of Departmental Committee of Min. Health (Report issued July 27th, 1928). There is no evidence that the use of ethyl petrol involves more danger to health than the ordinary, but the precautions suggested by the U.S. Committee should be carried out, e.g., labelling of cans and pumps, leaflets, and dyeing of the substance red. Warning against use for purposes other than as motor fuel, e.g., cooking and cleaning. In no case does the amount of lead tetraethyl in commercial spirit exceed 1 in 1300 by volume or 1 in 650 by weight. The deaths in the U.S.A. not attributed to the diluted mixture (ethyl petrol). Drivers and garage employees in U.S.A. gave no definite signs of poisoning after exposure for 2 years.—*Brit. med. J.*, ii/1928, 219.

PODOPHYLLUM

Podophyllum (B.P.). Contains not more than 2% of other organic matter. Podophyllum, *N.F. VII*, contains not more than 2% of foreign organic matter, not more than 2% of acid-insoluble ash and yields not less than 5% of resin of podophyllum; it is assayed by continuous extraction, followed by percolation and adjustment to volume with alcohol; an aliquot part is shaken with equal volumes of chloroform and hydrochloric acid (0.6%) and the acid layer extracted with three further portions of 1½ volumes of alcohol-chloroform (1:2); after shaking the alcohol-chloroform liquids with a further volume of the hydrochloric acid and washing this with three 1½ volume portions of alcohol-chloroform, the combined extractions are evaporated to dryness, 1 ml. of dehydrated alcohol added and dried at 80°.

A tentative method for the determination of resin in podophyllum is described in *Methods of Analysis (A.O.A.C., 1940, 598)*.

Podophyllum Indicum (B.P.). Contains not more than 2% of foreign organic matter.

T. A. Henry found that the action of both podophyllum and Indian podophyllum is due to podophyllotoxin (purgative) and podophylloresin (purgative and cholagogue). The Indian is richer in the former.

The following histological features of Indian podophyllum serve to distinguish it from the American drug: (1) The complete absence of epidermal cells with brown contents. (2) The presence of cluster crystals of calcium oxalate, which are comparatively few in number and do not exceed 60 microns in

diameter. (3) The almost complete absence of pericyclic fibres. (4) The presence of a fairly large amount of thin-walled, isodiametric cork cells. (5) The sclerenchymatous cells, which are irregular or somewhat contorted in form, are more abundant than in American podophyllum. As in the American drug, there is much starch, individual granules not exceeding 35 microns in diameter.—T. E. Wallis and S. Goldberg, *Quart. J. Pharm.*, 1937, 311.

Podophylli Resina (B.P.). Loss at 100°, not more than 5%. Ash, not more than 1%. Matter insoluble in dilute solution of ammonia, not more than 10% for resin from podophyllum, and not more than 50% for resin from Indian podophyllum. Resina Podophylli, *N.F. VII*, is obtained from *Podophyllum peltatum* only; ash, not more than 1.5%. A test for distinction from resin obtained from *Podophyllum Emodi* is included:—0.4 g. is added to 3 ml. alcohol (60%) and then shaken gently with 0.5 ml. of potassium hydroxide solution; the mixture should not gelatinise. Résine de Podophylle, *Fr. Cx.* 1937, yields not less than 75% of ether-soluble resins and not less than 65% of chloroform-soluble resins. Podophyllum, *P. Helv. V*, is the mixture obtained by precipitation with water from an alcoholic extract of the rhizome of *Podophyllum peltatum* containing not less than 40% of podophyllotoxin. *Assay.* Shake frequently during 30 minutes 0.45 g. in fine powder with 15 ml. of chloroform; transfer 10 ml. of the filtered solution (=0.3 g. of the drug) to a tared flask with 50 g. of light petroleum, collect the precipitate on a tared filter and wash the flask and filter with 20 ml. of light petroleum. Dry the flask and filter with the precipitate for 1 hour at 70° and weigh. The dried residue should weigh not less than 0.12 g.

POTASSII HYDROXYQUINOLINI SULPHAS

Potassii Hydroxyquinolini Sulphas (B.P.C.) may be a mixture of 8-hydroxyquinoline sulphate and potassium sulphate or of 8-hydroxyquinoline and potassium acid sulphate. It partly liquefies at 172° to 178° and yields from 30 to 33% of sulphated ash.

Oxychinolinum sulfuricum, *P. Helv. V*, is oxyquinoline sulphate containing not less than 95% of $(C_9H_7ON)_2H_2SO_4$. It is assayed by dissolving 0.5 g. in 250 ml. of water, mixing 50 ml. of the solution in a closed flask with 25 ml. of dilute hydrochloric acid and 22 ml. of N/10 bromate-bromide solution, and adding 1 g. of potassium iodide after 1 minute. The liberated iodine is then titrated with N/10 sodium thiosulphate in the usual manner and starch is used as indicator. Each ml. of bromate-bromide solution is equivalent to 0.0048525 g. of $(C_9H_7ON)_2H_2SO_4$.

Chiniofonum (B.P. Add. I) is a mixture of approximately 4 parts by weight of 7-iodo-8-hydroxyquinoline-5-sulphonic acid and 1 part of sodium bicarbonate. Contains 28.2 to 29.6% of I and 18 to 22% of $NaHCO_3$. Assayed for iodine by ignition with sodium carbonate, solution in water, filtration and neutralisation with sulphuric acid to methyl orange, followed by oxidation with

bromine and sulphuric acid, removing oxidising substances remaining in solution after boiling for 10 minutes with phenol in glacial acetic acid, finally titrating the iodine liberated on the addition of potassium iodide with N/10 sodium thiosulphate; 1 ml. of N/10 sodium thiosulphate = 0.002116 g. of I. Sodium bicarbonate determined by the interaction in a closed vessel for at least 12 hours of N/10 barium hydroxide and the carbon dioxide produced by interaction of the substance and water and afterwards with dilute hydrochloric acid and water, followed by back titration of the N/10 barium hydroxide with N/10 oxalic acid to phenolphthalein. Chiniofonum, *U.S.P. XII*, contains 26.5 to 29% of I and complies with tests for free iodine and iodide.

Assay of Chiniofonum, U.S.P. XII. Heat on a steam-bath 0.4 g. with 15 ml. of aqueous sodium hydroxide solution (1 in 20), contained in a 500-ml. Erlenmeyer flask; when completely dissolved, add 25 ml. aqueous potassium permanganate solution (1 in 15) and several small pieces of porcelain. After rinsing the inner wall of the flask with a small quantity of distilled water, place a small short-stemmed funnel in the mouth of the flask and heat on a steam-bath for 1 hour, rotating the flask at 5-minute intervals. Allow to cool to room temperature, and add 75 ml. of distilled water, followed by 20 ml. of dilute sulphuric acid. Rotate the flask and add, all at once, 15 ml. of aqueous sodium bisulphite solution (1 in 5). When the solution has become colourless, add potassium permanganate solution, drop by drop, until the liquid is faintly yellow. Immediately add sodium bisulphite solution, drop by drop, to discharge the colour. Add 2 ml. of glacial acetic acid, 1 g. of dextrin, 1 g. of freshly powdered ammonium carbonate, and 0.5 ml. diiodofluorescein (0.5% in 75% alcohol). Titrate against N/10 silver nitrate in diffused light until the colour changes from pale yellow to pink; 1 ml. of N/10 silver nitrate = 0.01269 g. of I.

Tabellæ Chiniofoni (U.S.P. XII). Contain iodine equivalent to 26 to 29% of the labelled amount of chiniofon, including all tolerances. A test for inorganic iodine is included. A weighed quantity of powdered tablets is assayed by the process described for chiniofon.

POTASSIUM

Notes on other potassium salts are included under the corresponding acids (see Index).

Potassii Bicarbonas (B.P.). $\text{KHCO}_3 = 100.1$. Contains from 99% to the equivalent of 100.5% of KHCO_3 . The *B.P. Add. I* modifies the limit test for iron by dissolving the potassium bicarbonate in 20 ml. of dilute nitric acid FeT . The *U.S.P. XII* substance should contain not less than 99% of KHCO_3 , after drying over sulphuric acid.

Potassii Carbonas (B.P. Add. I). Loses from 14 to 18% when dried at 200° to 300° , and then contains not less than 99% of K_2CO_3 . Potassii Carbonas, *U.S.P. XII*, dried to constant weight at 180° , contains not less than 99% of K_2CO_3 . Loss at 180° , 10 to 16.5%. Carbonate Neutre de Potassium, *Fr. Cx.* 1937, loses not more than 5% at red heat and contains 95% of the anhydrous salt.

Potassii Chloras (B.P.). $\text{KClO}_3 = 122.6$. Contains not less than 99% of the pure salt. Assayed by digestion, for 20 minutes at 50° , of a solution with acid ferrous sulphate solution and potassium iodide, followed by dilution and titration of the liberated

iodine with N/10 sodium thiosulphate, a blank titration being made. The *N.F. VII* assays by reducing a solution with acid ferrous sulphate solution by boiling for 10 minutes, manganous sulphate solution being added and the excess ferrous sulphate titrated with N/10 potassium permanganate, a blank determination being performed; a purity of 99% is required.

The following assay is recommended by the Sub-Committee on Inorganic Chemicals of the Committee on General Chemistry:—Dissolve about 0.3 g., accurately weighed, in 10 ml. of water in a stoppered flask, add 0.5 g. of sodium nitrite dissolved in 10 ml. of water, followed by 20 ml. of nitric acid; stopper the flask and set aside for ten minutes; add 100 ml. of water and sufficient solution of potassium permanganate to produce a permanent pink colour; decolorise by the addition of a trace of ferrous sulphate; add 30 ml. of N/10 silver nitrate, filter, and titrate with N/10 ammonium thiocyanate, using solution of ferric ammonium sulphate as indicator. Each ml. of N/10 silver nitrate is equivalent to 0.01226 g. of KClO_3 .—(*British Pharmacopœia Commission Report*, No. 14, September 1939.)

Tabellæ Potassii Chloratis (*N.F. VII*). Contain 94 to 106% of the labelled amount of potassium chlorate, including all tolerances. Assayed by dissolving in water, treating with acid solution of ferrous sulphate and titrating the excess ferrous sulphate with N/10 potassium permanganate.

Schulze's Maceration Mixture. A mixture of potassium chlorate 10 (moistened with water), with nitric acid 40; or a solution of 0.06 g. potassium chlorate in water 100 ml. and 1 ml. of nitric acid. For separation of muscle fibre in animal, and ligneous tissue in vegetable, histology. Distinguish from the following:—

Schulze's Chlor-Zinc-Iodine Reagent for Cellulose. Dissolve 110 g. of zinc in 300 ml. of pure hydrochloric acid, and evaporate to 150 ml. (sp. gr., about 1.8). Dissolve separately 12 g. of potassium iodide in as little water as possible; add 0.15 g. of iodine. Mix the solutions, and filter if necessary through asbestos.—Bower and Wynne Vaughan.

Tabellæ Potassii Permanganatis (*N.F. VII*). Tablets of 0.3 g. or more contain 94 to 106%, and tablets of less than 0.3 g. contain 92.5 to 107.5%, of the labelled amount of potassium permanganate, including all tolerances. Assayed by heating at 80° with excess N/10 oxalic acid in acid solution and back titrating with N/10 potassium permanganate.

Potassii Hydroxidum (*B.P. Add. I*). $\text{KOH} = 56.10$. Contains total alkali, by titration with N/1 sulphuric acid to methyl orange, equivalent to not less than 85% of KOH , and not more than 4% of K_2CO_3 . Determined by addition of barium chloride solution and titration with standard hydrochloric acid using phenolphthalein indicator, followed by further titration of the same liquid to the end-point of bromphenol blue; the second titration is equivalent to the K_2CO_3 and the sum of the titrations is equivalent to the total alkali. Potassii Hydroxidum, *U.S.P. XII*, contains not less than 85% of total alkali as KOH , of which not more than 3.5% is K_2CO_3 . Assayed by titration with N/1 sulphuric acid to phenolphthalein, continuing the titration to methyl orange. The *Fr. Cx.* 1937 titrates the total alkali to phenolphthalein and the hydroxide after precipitation of the carbonate with barium chloride; contains not less than 85% of hydroxide and not more than 2% of carbonate.

Liquor Potassii Hydroxidi (*B.P.*). Contains from 4.75 to 5.25% w/v of total alkali, calculated as KOH . Liquor Potassii Hydroxidi, *N.F. VII*, contains from 4.5 to 5.5% w/v of total alkali, calculated as KOH , of which not more than 0.35% w/v is K_2CO_3 .

Detection and Determination of Potassium. Potassium may be detected and determined by means of sodium 6-chloro-5-nitrotoluene-3-sulphonate, $\text{CH}_3\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2\cdot\text{Cl}\cdot\text{SO}_3\text{Na}$. The reagent is used as a 10% aqueous solution and yields a white crystalline precipitate, either at once or on standing, with solutions of potassium compounds. To a solution containing about 0.1 to 0.2 g. of potassium in 10 ml. 50 to 100% excess of the reagent is added. The whole is heated to the boiling-point and the conditions should be such that the potassium salt is just dissolved, water being added or the solution evaporated as may be necessary. The liquid is allowed to stand overnight at a temperature not exceeding 5° , and then filtered through a tared, sintered glass crucible, washed with a saturated aqueous solution of the potassium derivative of the reagent and, finally, rinsed with a small quantity of water, dried at 120° and weighed. Each gramme of precipitate is equivalent to 0.135 g. of K. The test solution must be free from barium, and ammonia, if present, must be removed by boiling with sodium hydroxide.

Determination of Potassium as Potassium Silver Cobaltinitrite. 2 ml. of a potassium solution free from halogens and containing from 0.03 to 2 mg. of potassium is acidified in a centrifuge tube with 1 drop of glacial acetic acid. 1 ml. of 0.7% silver nitrate is added and the solutions well mixed with a glass rod; 1 ml. of 80% acetone is added gradually and the tube and glass rod are then placed in an ice-bath for 5 minutes. 1 ml. of freshly prepared 25% sodium cobaltinitrite solution, also cooled in the ice-bath for 5 minutes, is added drop by drop with stirring after each addition; after 0.9 ml. of reagent has been added, the glass rod is allowed to drain and is then rinsed with the remaining 0.1 ml. The tube is kept in the ice-bath for 2 hours, then centrifuged at 3000 r.p.m. for 3 minutes. The clear liquid is decanted, the tube inverted to drain, and its mouth and upper part wiped with filter paper. 3 ml. of 50% acetone is added gradually down the sides of the tube in small quantities at a time, the tube again centrifuged and drained as before and then 3 ml. of 80% acetone is run in and the precipitate stirred with a glass rod which is drained and rinsed with 2 ml. of 80% acetone. The tube is centrifuged and the washing with 80% acetone and centrifuging are repeated twice. The potassium is determined indirectly by means of the nitrite content of the potassium silver cobaltinitrite complex. An excess of N/50 ceric sulphate is added to the dry precipitate followed by 2 ml. of 2N sulphuric acid, the tube is placed in a boiling water bath to complete the decomposition, and the contents transferred to an Erlenmeyer flask using further quantities of 2N sulphuric acid for rinsing. The flask is then boiled and cooled, the solution is treated with excess of N/50 ferrous ammonium sulphate and is then titrated with N/50 ceric sulphate using 0.1% aqueous solution of erioglaucine as indicator. 1 ml. of N/50 ceric sulphate corresponds to 0.1087 mg. of potassium. The accuracy of the method is within 1% and is not affected by the presence of other metals.—A. M. Ismail and H. F. Harwood, *Analyst*, 1937, 443.

Modifications are described of the cobaltinitrite method of estimating potassium, which render it applicable to urine, serum, etc., containing small amounts of potassium.—G. B. West, *Quart. J. Pharm.*, 1941, 26.

PYRETHRUM

Pyrethri Flos (B.P.C.). Contains not less than 0.4% of pyrethrin I. Ash limit, 8%. Acid-insoluble ash limit, 1%. Assayed by the B.P.C. '34 process: continuously extract 10 g. (in 85 powder) with petroleum (b.p. 40° to 50°); reflux the solution (measuring about 50 ml.) with 5 ml. of N/1 sodium hydroxide in methyl alcohol, in a micro-Kjeldahl apparatus, on a water-bath for 2 hours; acidify the cooled mixture with N/1 sulphuric acid and steam distil till 150 ml. of aqueous distillate is collected below the light petroleum; extract the whole distillate in a separator with the addition of 10 g. of sodium chloride, with the light petroleum and two further portions; the petroleum liquids and alcohol and water rinsings of the separator are titrated with N/50 sodium hydroxide

till a distinct pink colour is produced to phenolphthalein after vigorous shaking; deduct the blank titration required for the light petroleum; 1 ml. of N/50 sodium hydroxide is equivalent to 0.0066 g. of pyrethrin I.

The *Fr. Cx.* 1937 describes an assay process for pyrethrins I and II in *Chrysanthème Insecticide*; dried flowers of good quality should contain 0.5 to 1.2%; the powder is subjected to continuous extraction with light petroleum ether during 6 hours, the solvent evaporated and the residue dissolved in ether; after shaking with normal potash the ether is evaporated, the residue refluxed with N/1 potash in methyl alcohol, the alcohol evaporated and the residue dissolved in water. The solution is shaken with ether and alcohol and the ethereal layers treated with sodium chloride solutions. The filtered aqueous liquids rendered just acid with dilute hydrochloric acid are exhausted with ether, finally titrating the evaporated ethereal solutions with N/5 methyl-alcoholic potash to phenolphthalein. A physiological test is also included. *Flos Pyrethri, P. Helv. V*, yields to ether by continuous extraction not less than 5% of extractive; ash, not more than 8.5%.

Kenya pyrethrum is sold on a guaranteed pyrethrin content of 1.3%, as opposed to 0.9% in Japanese pyrethrum. Moisture content of Kenya flowers runs from 5 to 7%; Japanese flowers to close on 15%. In Kenya the production is scientifically controlled, the flowers being kiln-dried under strictly controlled conditions.—per *Mfg. Chem.*, 1941, 236.

Determination of the Pyrethrins.

A number of methods have been published for the determination of the pyrethrins I and II. All suffer from some disadvantages and in each case concordant results can only be obtained by closely adhering to the details of the methods. Owing to the presence of substances such as free chrysanthemic acids, which interfere more or less with the process, results obtained by the different acid methods are not absolutely comparable. In all cases the pyrethrum flowers are extracted with petroleum ether. The assay of kerosene preparations, such as fly-sprays, which may contain perfumes, is never satisfactory due to interfering substances present as impurities or as components of the perfumes used.

The pyrethrins I and II may be determined either separately or combined. It is generally stated that pyrethrin I is more toxic to insects than pyrethrin II and that they are present in about equal proportions, but this is not always so. The process given as a standard in the *B.P.C.* 1934 determines the pyrethrin I only and is the best and simplest for this purpose.

Determination of Total Pyrethrins I and II. This process depends upon the reducing power of the pyrethrins on alkaline copper solution; it is a modification of the method of Folin. The temperatures and times given in the method must be very strictly adhered to and a bulb tube of the correct size must be used. Complete details of the process and a table showing the comparison between the reducing power of the pyrethrins and dextrose, which is used as a standard, are described.—C. B. Gnadinger and C. S. Corl, *J. Amer. chem. Soc.*, 1929, 3054.

Determination of Pyrethrins I and II Separately. The pyrethrins I and II are converted to the chrysanthemum acids by saponification and liberation with acid. The volatile monocarboxylic acid which is formed from the pyrethrin I is distilled off and estimated by titration. The residue from the distillation containing the dicarboxylic acid derived from the pyrethrin II is extracted and determined separately by titration.—H. A. Seil, *Soap*, 1934, 10, 89. A modification of this process.—Ripert, *Ann. Falsif.*, 1934, 25, 580 and 595.

Pyrethrins I and II may be determined quantitatively by hydrogenation with palladium as catalyst yielding hexahydropyrene and the acids of pyrethrins I and II. The carboxylic acid of I is separated by steam distillation and titrated with alkali, and the dicarboxylic acid of II is extracted from the residual filtrate

with ether and subsequently titrated.—F. B. La Forge and F. Aoree, *Soap and Sanitary Chemicals*, 1941, 17, No. 1, 95.

Determination of Pyrethrin II. Pyrethrin II being a methyl ester, yields methyl iodide on refluxing with hydriodic acid. The methyl iodide is estimated volumetrically by converting it into iodic acid, liberating the iodine by means of potassium iodide and titrating with sodium thiosulphate. This method gives results which are lower than those obtained by the acid method.—H. L. Haller and F. Acree, *Industr. Engng Chem., anal. Edn.*, 1935, 343.

Determination of Pyrethrin I in Insecticides. The Wilcoxon method has been adapted to the determination of pyrethrin I in sprays containing essential oils, derris resins, tobacco extract, etc.—D. A. Holaday, *Industr. Engng Chem., anal. Edn.*, 1938, 5.

Freshly-ground pyrethrum flowers, in containers of different kinds, lose from 30 to 43.6% of pyrethrins within a year. Powdered and ground flowers in closed tins continue to lose pyrethrins for more than 2 years but not so rapidly. Storage under suitable conditions is therefore important.—C. B. Gnadinger and C. S. Corl, *Industr. Engng Chem.*, 1932, 901.

Fly Sprays. An efficient fly spray should contain not less than 0.09% of total pyrethrin. Killing-power is increased by the use of a wetting-agent such as coconut oil soap or diglycololeate.—*Pharm. J.*, i/1933, 129.

Evaluation of the Toxicity of Pyrethrum Insecticides. Chemical analyses of pyrethrum extracts proving unreliable for this purpose biological methods are used. Generally they follow the same lines, viz. (1) spraying a definite amount of insecticide of a known concentration at a controlled pressure; (2) recording the time when the insects become paralysed; (3) ascertaining the number of recoveries by setting the insects aside for a definite time. It is preferable to adjust the concentrations so as to obtain a "kill" varying between 40 and 60%.

The National Association of Insecticide and Disinfectant Manufacturers in the U.S.A. have adopted an Official Control Insecticide for purposes of standardisation. Tests are conducted in the Peet and Grady method and the standard error of the mean difference between the average kill and the O.C.I. must be less than three. An example of the method of calculation is given. The mean difference is utilised for grading insecticides.—W. E. Edmonton, *Pharm. J.*, ii/1939, 289. See also F. P. Mackie and H. S. Crabtree, *Lancet*, ii/1938.

PYROXYLINUM

Pyroxylinum (B.P. Add. I). The substance dried at 100° for one hour contains 11.5 to 12.3% of nitrogen. To determine the nitrogen content, a weighed portion of the dried substance is transferred with nitrogen-free sulphuric acid to a mercury-filled nitrometer and shaken, and the liberated nitric oxide measured. Kinematic viscosity at 20° of a 3% w/v solution of the dry substance in acetone, not less than 370 centistokes. Pyroxylinum, *U.S.P. XII*, saturated with alcohol in a dish placed in cold water, ignited at the top and afterwards heated to redness, leaves not more than 0.3% of ash. Yields not more than 0.3% of water-soluble substances.

RHEUM

Rheum (B.P. Add. I). Rhubarb should contain not more than 2% of foreign organic matter. Alcohol (45%) soluble extractive, not less than 35%. Acid-insoluble ash, not more than 1%. A limit test for rhapontic rhubarb is included when on examination in screened ultra-violet radiation with a lens it shows no shining

violet points. Rheum, *U.S.P. XII*, yields not less than 30% of diluted alcohol-soluble extractive; Rheum rhaponticum is excluded.

Rhizoma Rhei, *P. Helv. V*, yields not more than 13% of total ash and not more than 1% of acid-insoluble ash; it contains from 4.23 to 6.56% of free and combined anthracene derivatives calculated as chrysophanic acid, and complies with the following test for the absence of rhapontic rhubarb:—Boil 10 g. of powdered rhubarb with 50 ml. of dilute alcohol for 15 minutes; filter and evaporate the filtrate to 10 ml.; allow to cool and treat with 15 ml. of ether; after 24 hours no crystals should be deposited which when dried and treated with concentrated sulphuric acid produce a purple-red colour.

The method of *P. Helv. V*, for the assay of rhubarb is based upon false assumptions and is totally unnecessary.—L. Rosenthaler, per *J. Amer. pharm. Ass. Abstr.*, 1936, 42.

Fluorescence Test for Rhapontic Rhubarb. On exposure to ultra-violet light rhapontic rhubarb exhibits a violet fluorescence, while genuine Chinese rhubarbs give a velvety brown fluorescence.

Using genuine Chinese rhubarb as a standard for comparison, one can easily detect as little as 1% of added rhapontic rhubarb, using paper strips soaked in a tincture made from the drug. The whole operation must be conducted in a dark room. The wide variation in the intensities of the fluorescence of different samples of rhapontic rhubarb makes it very difficult to carry out exact quantitative determinations by this method.—T. E. Wallis and E. R. Withell, *Quart. J. Pharm.*, 1934, 574.

The presence of the rhapontic variety in galenical preparations can be detected by the fluorescence test. A pledget of cotton or other form of cellulose is immersed in a tincture or other galenical containing rhapontic rhubarb, and then washed in water. It gives a bright blue fluorescence in screened ultra-violet light (wave-length 310—390 μ).—S. K. Crews, *Quart. J. Pharm.*, 1936, 434.

Evaluation on chrysophanic acid content, the results not being absolute, but well adapted for comparative purposes.—A. Tschirch and P. Schmitz, *Quart. J. Pharm.*, 1929, 463.

In the *B.P.* formulæ for pills, vegetable drugs such as aloes, ginger, etc., are taken in "fine powder," and it may be assumed therefore that Pulv. Asafoet. is not sanctioned in Pil. Aloes et Asafoet., or Pulv. Myrrh. in Pil. Rhei Co. Since both these powders are well known in commerce it would have been helpful if the monographs on these and other vegetable drugs had provided the user with information as to which drugs were official in powder form.—*Pharm. J.*, ii/1932, 147.

SACCHARINUM

Saccharinum (B.P.C.). $C_7H_5O_3NS = 183.1$. Determined by the *B.P.* method for Saccharinum Solubile, it contains not less than 97% of the pure substance. M.p., not below 225°. Saccharinum, *U.S.P. XII*, leaves not more than 0.2% of ash, and complies with tests for glucose and lactose, benzoic or salicylic acid and ammonium compounds; 0.2 g. complies with a test for carbonisable substances.

Official qualitative and quantitative methods for the determination of saccharin in foods are described in *Methods of Analysis (A.O.A.C., 1940, 458)*.

Detection in Foodstuffs. To 25 g. of the sample add sufficient boiling water to produce 75 ml. and after one hour, with occasional shaking, acidify with 3 ml. of glacial acetic acid, and add 5 ml. of 20% neutral lead acetate solution. Dilute the mixture to 100 ml., allow to stand for 20 minutes, filter and acidify an aliquot portion (60 ml.) with 5 ml. of hydrochloric acid. Extract the mixture with equal parts of ether and light petroleum (b.p. 30° to 60°), wash the ethereal solution with 5 ml. of water and allow the solvent to evaporate at room temperature. Heat the residue with 5 ml. of a solution of phenol in an equal weight of sulphuric acid at 135° to 140° for 2 hours, dissolve the product in a little hot water and pour into about 250 ml. of cold water. After 3 hours, filter, make alkaline with 10% sodium hydroxide solution and dilute to 500 ml. A magenta or reddish purple colour indicates the presence of saccharin in the original sample. Vanillin if present must be removed by repeated extraction of the ethereal extract with carbon tetrachloride.—W. F. Reindollar, *J. Ass. off. agric. Chem., Wash.*, 1940, 23, 288.

Saccharinum Solubile (B.P.). $C_7H_4O_3NSNa \cdot 2H_2O = 241 \cdot 1$. Contains not less than 98% of the pure substance. M.p. of the washed and dried separated saccharin, not lower than 226°. Complies with tests for absence of benzoate and salicylate and limit of *p*-sulphaminobenzoic acid. Assayed by the B.P. '32 process: boil 0.7 g. with 10 ml. of 30% sodium hydroxide solution for 2 minutes; cool and reflux with 15 ml. of hydrochloric acid for 50 minutes; cool, rinse condenser with 50 ml. of water, and remove acid vapours with a current of air; distil the ammonia liberated on addition of 20 ml. of 30% sodium hydroxide solution into excess N/10 sulphuric acid and back titrate with N/10 sodium hydroxide to methyl red. Saccharinum Sodicum, U.S.P. XII, complies with tests for neutrality, benzoate or salicylate, ammonium compounds, etc.

Tabellæ Saccharini Sodici (U.S.P. XII). Contain 95 to 110% of the labelled amount of $C_7H_4O_3NSNa \cdot 2H_2O$, including all tolerances. Complies with a limit test for ammonium salts. Assayed by refluxing for 1 hour a weighed quantity of powdered tablets with water-hydrochloric acid mixture (40 : 25), followed by an ammonia distillation.

The sweetness of canned fruits in syrup of 30° Brix may be increased to the equivalent of 38° Brix, or about eight degrees of a 38° syrup may be replaced by saccharin without producing foreign flavours. The apparent sweetness of soluble saccharin in syrup of 30° is about 300 to 400 times that of sucrose. Saccharin has little effect on the internal corrosion of cans.—per *Analyst*, 1941, 464.

Dulcin. Dulcin may be used to increase the sweetness of canned fruits from the equivalent of at least 30° to at least 40° syrup, or to replace about 10° of a 30° syrup. The addition of greater amounts produces foreign flavours. The apparent sweetness of dulcin in a syrup of about 30° Brix is about 300 times that of sucrose. On the whole, dulcin is probably less toxic and gives better results than saccharin in canned fruits.—per *Analyst*, 1941, 464.

Determination. About 0.4 g. of sample is rinsed into a Kjeldahl flask with 25 ml. of 18N sulphuric acid. A small quantity of pumice powder is added, and the mixture gently boiled for three hours under a reflux air condenser. When cool, water is carefully added and the contents of the flask made alkaline with 30% sodium hydroxide solution. The alkaline solution is steam-distilled, the ammonia evolved is collected in 40 ml. of N/10 sulphuric acid and the excess of acid estimated. A blank determination is done and the result calculated on the difference of the readings. Each ml. of N/10 sulphuric acid is equivalent to 0.018 g. of dulcin. Results obtained by this method were consistent but high, averaging $103.5 \pm 0.5\%$ and the authors are unable to explain this figure satisfactorily.—J. F. Hirst, F. Holmes, and G. W. G. MacLennan, *Analyst*, 1941, 450.

Colorimetric Determination. Dulcin can be hydrolysed quantitatively to *p*-phenetidine by boiling with 3N sulphuric acid for about 4 hours. By

diazotising the *p*-phenetidine and forming an azo dye with phenol in alkaline solution, dulcin can be estimated. The resulting colour is matched against similar solutions containing known amounts of *p*-phenetidine hydrochloride, and the result is converted to dulcin by multiplying by 1.037. Saccharin has no appreciable effect on the result, and neither has ammonia, which may be produced during the hydrolysis. Sugar and similar substances interfere with the process and composite articles containing these are first extracted with organic solvents to remove essential oils, etc., and then shaken with ethyl acetate to remove the dulcin.—J. Longwell and C. S. Bass, *Analyst*, 1942, 15.

Determination in Beverages. Twenty-five ml. of the sample, or of the corresponding extract after distillation of an alcoholic beverage, are extracted with light petroleum. The petroleum extract is washed with 5 ml. of water and rejected, and the washings are added to the main solution. The dulcin is extracted from this solution with three 30-ml. portions of ethyl acetate, and the united extracts washed with 10 ml. of water. The ethyl acetate is distilled off and the residual dulcin dissolved in 5 to 10 ml. of acetone and rinsed in a 10-ml. Kjeldahl flask. After evaporation of the acetone, 5 ml. of 18N sulphuric acid are added, and the solution is boiled under a reflux air condenser for three hours. It is then cooled, diluted, made alkaline with 15 ml. of 30% sodium hydroxide solution and steam-distilled. The ammonia evolved is trapped in 25 ml. of water and the distillation continued until about 180 ml. have been collected. The distillate is made up to 200 ml.; 40 ml. of this solution are Nesslerised in a 50-ml. tube, and the colour is compared with that developed in equal volumes of water containing 1.5, 2.0 and 2.5 ml. of standard ammonium chloride solution. A blank determination is made at the same time. The standard solution contains 0.2125 g. of ammonium chloride per litre (1 ml. is equivalent to 0.0007145 g. of dulcin).—J. F. Hirst, F. Holmes, and G. W. G. MacLennan, *Analyst*, 1941, 451.

Detection in Saccharin. 100 mg. of the sample and 100 mg. of resorcinol are heated for 1½ to 2 minutes at exactly 180° in 2 ml. of sulphuric acid. The red liquid is cooled, diluted with 5 ml. of water and made alkaline with sodium hydroxide; it then has an orange-red colour and green fluorescence due to saccharin. On oxidation (with an alcoholic solution of iodine, bromine or silver nitrate, etc.) and dilution with 100 ml. of water a violet colour is produced if dulcin is present in the saccharin to the extent of 1%.—H. J. Vlezenbeek, *Pharm. Weekbl.*, 1937, 127.

SANTONICA

Santonica (B.P.C.). Contains not less than 2% of santonin. Assayed by maceration with chloroform, filtration, recovering most of the chloroform from a portion of the filtrate, and with addition of 1.2% baryta, heating off the remaining chloroform; extraction of the filtered and washed acidified liquid is effected with chloroform; the residue after evaporation of the solvent is dissolved in dehydrated alcohol, diluted with hot water to 15% *w/w* of alcohol and filtered; after 24 hours the separated santonin is collected on a tared filter, washed with 15% *w/w* alcohol and dried; a correction for loss due to solubility is allowed.

Flores Cinæ, *P.G. VI*, by the process prescribed, yields not less than 2% of santonin. Flos Cinæ, *P. Helv. V*, is required to show a santonin content of not less than 1.8%. Assayed by the following process:—Shake 10 g. for ½ hour with 100 g. of benzene, and filter; recover the benzene from 81 g. of filtrate (= 8 g. of drug), removing the last traces in an oven at 103° to 105°, cool, dissolve the residue by refluxing for 15 minutes with 40 ml. of 15% (*w/w*) alcohol. Filter through cotton wool, warm and wash flask and funnel twice with 5 ml. of 15% alcohol. Again cool, add 0.1 g. of

kaolin and reflux a second time for 15 minutes and filter hot through a 6 cm. diam. filter, washing with 2 portions of 5 ml. of 15% alcohol. Set aside in the dark for 24 hours, weigh the solution and filter, washing three times with 2 ml. of water. Dry the filter for 1 hour at 103° to 105°, and dissolve the crystals with 2 portions of 5 ml. of chloroform. Evaporate, dry for 1 hour at 103° to 105° and weigh. For each g. of solution from which the santonin was crystallised add a correction of 0.0006 g. The assay process of the *P.G. VI* is similar.

Assay. Santonin in wormseed cannot be determined as the 2:4-dinitrophenylhydrazine since other constituents interfere, giving a high result. The following method may be used:—The powdered drug is moistened with ammonia, dried, and extracted with benzene. The residue, after evaporating the benzene, is digested on a water-bath with a saturated solution of barium hydroxide, and the liquid filtered, acidified with hydrochloric acid and set aside for 24 hours to allow the santonin to crystallise. The crystalline residue is collected on a sintered glass crucible, washed with a little water, dried at 100° and weighed.—M. M. Janot and M. Mouton, *Bull. Sci. pharm.*, 1936, 43, 708.

Santoninum (B.P.). $C_{18}H_{18}O_3 = 246.1$. M.p., 171° to 174°. Ash, not more than 0.1%. 0.1 g. with 2 ml. of sulphuric acid is not darker than pale brown, and on dissolving forms a clear solution not darker than yellow. The alcoholic solution should be neutral to litmus. Santoninum, *N.F. VII*, leaves not more than 0.1% of ash. 0.5 g. boiled with 20 ml. of water and 2 ml. of dilute sulphuric acid, cooled and filtered, produces no cloudiness with Mayer's reagent or with iodine solution, even after standing for 3 hours; 0.1 g. complies with the specified test for carbonisable substances. Santonine, *Fr. Cx.* 1937, melts at 170°, α_D (2% solution in chloroform) -172.26° .

Official methods for the determination of santonin in mixtures are described in *Methods of Analysis (A.O.A.C., 1940, 614)*. The methods are a modified Langer's method and the dinitrophenylhydrazine method. A tentative method for the determination of santonin in santonica is also described (*ibid.*, 615).

SAPONES

Sapo Animalis (B.P.). Curd soap loses at 110°, 20 to 30%. In powder, loss at 110°, not more than 5%. Solidifying-point of the fatty acids, not less than 42°. Limit tests for alkali hydroxide, and free fatty acids, alkali carbonate and free fat are described. The *B.P. Add. I* raises the limit of free fat to 0.8%, and does not require the previously stated amount of 20 g. to be used for preparation of the fatty acids for the solidifying-point. Sodii Stearas, *U.S.P. XII*, complies with tests for alcohol-insoluble substances and free fatty acids; solidifying-point of the free fatty acids, not below 54°; loss, on evaporating at 80° a mixture of the substance and dried sand with alcohol and drying at 110°, not more than 5%.

Sapo Durus (B.P. Add. III). The sodium soap of suitable oil or oils or of fatty acids derived therefrom, other than coconut oil or palm kernel oil or their fatty acids. After being reduced to

thin shavings, or powdered, it complies with tests for limits of alkali hydroxide, free fatty acid and total free alkali described for Sapo Mollis. Unsaponified neutral fat and unsaponifiable matter, not more than 1%; chloride and other alcohol-insoluble substances, not more than 1%. A test for absence of resin is included. The separated fatty acids have the following characters:—Solidifying-point, not less than 28° (unless made entirely from olive oil); acid value, not more than 205. Loss at 100°, 20 to 30%. *Hard soap in powder* of the following higher limits is allowed:—alkali hydroxide increased by 30%, free fatty acid by 25%, total free alkali by 30%, unsaponified neutral fat and unsaponifiable matter, and chloride and other alcohol-insoluble substances by 20%. Loss at 110°, not more than 5%. Sapo Durus, *U.S.P. XII*, dissolved in alcohol, evaporated with sand, and dried at 110°, loses not more than 36%, or 10% for powdered soap. The dried soap yields not more than 1% of alcohol-insoluble matter and not more than 0.15% of water-insoluble substances. The fatty acids have a solidifying-point of 18° to 23°, an acid value of 185 to 205, and an iodine value of 83 to 92.

The *B.P.* figure of 0.5% for free fat in soaps is too low. The limit for Sapo Durus should be raised to 1%, for Sapo Mollis to 0.7%, and for Sapo Animalis to 0.7 to 0.8%.—Report of Sub-Committee, *Analyst*, 1934, 104.

Castile Soap (Jabón Castilla). By a Spanish Royal Order (Dec. 14, 1927) the name must apply only to a soap prepared in Spain, in the manufacture of which no fats other than olive oil have been used: containing not more than 2% chlorides (as sodium chloride): maximum water content 25%; maximum free alkali content 0.3%. The soap must be white and must be soluble in water or alcohol without residue.—*Pharm. J.*, i/1928, 164.

A method of determining the detergent action of soaps depends on the quantity of carbon which the soap solution will carry through filter paper. The "**carbon number**" is the number of grammes carried by 1 kg. of solution under standard conditions.—J. W. McBain and co-workers, *J. Soc. chem. Ind., Lond.*, 1923, 273.

Sapo Kalinus (*B.P.C.*). Potash soap yields, by the *B.P.* method for Sapo Mollis, not less than 44% of fatty acids of linseed oil, having an iodine value of 179 to 210. Complies with limit tests for chlorides and other alcohol-insoluble substances, alkali hydroxide, alkali carbonate, and free fatty acid.

Sapo Mollis (*B.P. Add. III*). Includes sodium or potassium soaps of a suitable vegetable oil or oils or the fatty acids therefrom, other than coconut oil, palm kernel oil or their fatty acids. Contains not less than 44% of fatty acids. Alkali hydroxide in 10 g. determined by titration of a solution in neutral alcohol after the addition of barium chloride solution, equivalent to not more than 1 ml. of N/10 hydrochloric acid. Free fatty acid in 10 g., equivalent to not more than 0.2 ml. N/10 sodium hydroxide. Total alkali in 10 g., equivalent to not more than 1 ml. N/10 sulphuric acid. Unsaponified neutral fat and unsaponifiable matter, not more than 0.8%; chlorides and other alcohol insoluble substances, not more than 3%. The separated fatty acids have an acid value of not more than 205, iodine value of not less than 83 and solidifying-point not higher than 31°. A test for absence

of resin is included. Fatty acids are determined by extraction of an acid solution with ether, washing the ether extracts with water, removal of the ether and drying the residue at 80°. Sapo Mollis Medicinalis, *U.S.P. XII*, is made from vegetable oils excluding coconut oil and palm kernel oil. Contains not more than 52% of moisture, determined by the toluene distillation method. Alcohol-insoluble matter, not more than 3%. Free alcohol-soluble alkali, calculated as KOH, not more than 0.25%; the fatty acids have an acid value of not more than 205 and iodine value, not less than 85. Sapo kalinus, *P.G. VI*, contains not less than 40% of the fatty acids of linseed oil.

Spiritus Saponatus (*B.P.C. Supp. II*). Determined by the process for Sapo Mollis, *B.P. Add. III*, yields not less than 27% *w/v* of fatty acids, which comply with the requirements described for the fatty acids of Sapo Mollis. Alcohol content, 28 to 31% *v/v* of ethyl alcohol.

Soft Soaps for Insecticides. The specification of the Association of British Insecticide Manufacturers (Bulletin No. 82: Ministry of Agriculture and Fisheries) requires soft soap for spraying purposes to dissolve completely in distilled water to a clear solution, to contain not more than 1% of free caustic alkali (KOH) or 3% of free alkali carbonate (K_2CO_3); not less than 95% of the total alkali, expressed as K_2O , to be K_2O . Percentage of fatty and resin acids to be declared.

Analysis of Soap. Methods of soap analysis have been under investigation by the Sub-Committee on Methods of Soap Analysis of the Analytical Methods Committee of the Society of Public Analysts. Reports describing recommended processes for carrying out the following determinations on soap have been issued by the Sub-Committee as follows:—No. 2, Unsaponifiable Matter (*Analyst*, 1935, 537); No. 3, Free Alkali (*ibid.*, 1937, 36); No. 4, Free Alkali and Silica in Silicated Soaps (*ibid.*, 1937, 865); No. 5, Rosin (*ibid.*, 1937, 868).

Detection of Soap Stains. The iron hydronamate test for carboxylic acids is a sensitive test for stains from commercial soaps in cases of criminal abortion. The stains on fabrics may be compared qualitatively in ultra-violet light.—M. W. Partridge, *Quart. J. Pharm.*, 1942, 21.

Triethanolamine. **Determination in Emulsions.** Mix about 5 g. of emulsion with 20 ml. of water, heat on a water-bath for 5 minutes, add sulphuric acid until a blue colour is given with congo-red paper and heat for another minute adding acid if necessary. Cool and extract with two 25 ml. quantities of ether. Shake the ethereal extract with 20 ml. of approximately N/10 sulphuric acid and distil off the ether. Re-extract the aqueous layer with ether and add it to the aqueous residue from the previous extraction. Heat on a water-bath to free from ether and precipitate the sulphuric acid with barium hydroxide solution. Warm the mixture, centrifuge, pour off the clear liquid, wash the residue and precipitate the excess of barium from the boiling liquid with carbon dioxide. Cool, filter, concentrate under reduced pressure to 3 ml. and wash the residue into a 50 ml. beaker with 15 ml. of ethyl alcohol through a Hirsch funnel, evaporate the alcohol and add 3 ml. of hydrochloric acid. Evaporate the excess of acid, collect the hydrochloride, dry in a steam-oven for 30 minutes and cool in a desiccator. Wash on to a sintered glass crucible with 4 quantities each of 5 ml. of pure isopropyl alcohol. Dry to constant weight at 100°. Weight of triethanolamine hydrochloride $\times 0.803$ gives the weight of triethanolamine. To allow for the solubility of triethanolamine in isopropyl alcohol add 0.003 g. to the ascertained weight of hydrochloride. The method can be applied with minor modifications to emulsions containing sulphonated alcohols or various other substances.—C. J. Eastland, N. Evers and T. F. West, *Analyst*, 1937, 261.

Identification of some Amine Emulsifiers. Several of the commonly used amino compounds used to replace soaps in cosmetics and similar preparations may be identified by the melting points of their sulphonyl or oxalate derivatives. Triethanolamine and tripropanolamine do not give crystallisable derivatives with these reagents.—I. S. Shupe, *J. Ass. off. agric. Chem., Wash.*, 1942, 25, 227.

SCILLA

Scilla (*B.P.* and *B.P. Add. IV*). Ash, not more than 6%. No biological assay is included and no standard is recommended by the Permanent Commission on Biological Standardisation of the League of Nations, since the biological assay of squill estimates the cardiac glycosides present, which are not the constituents responsible for its expectorant effect for which it is chiefly used in medicine. The *B.P. Add. IV* allows the use of Indian squill. The *N.F. VII* allows the use of *Urginea maritima* (Linné) Baker or of Indian squill, and requires the drug to contain not more than 2% of foreign organic matter and not more than 2% of acid-insoluble ash.

The *U.S.P. X* included the following biological requirement:—“Tincture of Squill injected into the ventral lymph sac of a frog has a minimum systolic dose of not less than 0.0055 c.c. and not more than 0.0065 c.c.; equivalent to not less than 0.00000046 g. and not more than 0.00000054 g. of ouabain for each g. of body weight of frog.” Thus ouabain was prescribed as a standard for squill and 100 ml. of a tincture was required to be equivalent to 8.3 mg. of ouabain. Ouabain is, however, an unsuitable standard for squill if different methods of assay are to be permitted, since the relative potency of squill and ouabain differs according to the species (see Burn, *Pharm. J.*, i/1927, 328).

Acetum Scillæ *B.P. Add. VI*. Contains active constituents equivalent to 10% *w/v* of squill. Sp. gr., 1.02 to 1.035; acidity of 10 ml. equivalent to 9.0 to 10.5 ml. of *N/1* sodium hydroxide, using phenolphthalein indicator.

Oxymel Scillæ (*B.P.*). Sp. gr., about 1.27; α_D of 25% *w/v* aqueous solution, using decolourising charcoal if necessary, + 0.6° to + 1.9°. Acidity of 20 ml. diluted with 20 ml. water, 8.0 to 9.0 of *N/1* sodium hydroxide to phenolphthalein indicator.

Galenical preparations develop a levorotation on standing, possibly due to hydrolysis of the squill glycosides. The average rotation of the tincture (*B.P. '32*) is -2.0°, and of the vinegar, -3.5°. —L. McGraham, *Analyst*, 1937, 539.

Scillaren is a crystalline glycoside of squill which could be used as a standard for biological estimations of squill if it were not a proprietary preparation. The average potency of tincture of squill *B.P. '32*, is equivalent to that of a 0.013% solution of Scillaren.

SENNA

Sennæ Folium (*B.P.*). Contains not more than 1% of stalks and not more than 2% of other foreign organic matter. Ash limit, 12%. Acid-insoluble ash limit, 3%. Senna, *U.S.P. XII*, contains not more than 8% of stems and not more than 2% of pods or other foreign organic matter. Acid-insoluble ash, not more than 3%. **Folium Sennæ**, *P. Helv. V*, consists only of the leaflets of *Cassia angustifolia* (Tinnevely senna), and may give up to 12% of ash.

Sennæ Fructus (*B.P.*). Contains not more than 2% of foreign organic matter. **Fructus Sennæ**, *P. Helv. V*, is the dried fruit of *Cassia acutifolia* and of *Cassia angustifolia*, and should yield not more than 6% of ash.

The standard is expressed in a very exceptional manner, and allows the presence of 2% of any other pods or even of dirt. Many of these new standards for crude drugs appear to be based on the *U.S.P. X*, but are unsatisfactory because they do not discriminate between harmless admixture and dangerous foreign organic matter.—*Pharm. J.*, ii/1932, 186.

Ether shaken with a slightly acidified senna extract gives the Bornträger reaction—a pink or red colour with ammonia water. If the ether be shaken with a saturated solution of nickel acetate, the aqueous layer turns red, and if this be separated and potassium hydroxide added a violet precipitate forms, which is stated to be a characteristic test for senna.—*U.S.D.*, 1926.

SINAPIS

Black Mustard contains the glycoside sinigrin, i.e., potassium myronate, $C_{10}H_{15}KNS_2O_9$, with myrosin, which is similar to the ferment emulsin in bitter almonds. This glycoside splits up under the influence of water with evolution of allyl isothiocyanate— $C_3H_5NCS=99.112$, the principal constituent of the essential oil—potassium acid sulphate and glucose. *Sinapis Nigra*, *U.S.P. XII*, contains not more than 5% of other seeds or foreign organic matter; yields not less than 0.6% of allyl isothiocyanate; assayed by maceration with water for 2 hours at 37°, addition of alcohol and distillation into a mixture of solution of ammonia and N/10 silver nitrate; after allowing this mixture to stand overnight it is heated in a boiling water-bath, cooled, adjusted to volume and filtered; an aliquot part is then acidified with nitric acid and titrated with ammonium thiocyanate. *P.G. VI* and the *Fr. Cx.* 1937 require black mustard seeds to yield at least 0.7% of the allyl compound.

White Mustard Seeds (*Sinapis alba*) do not yield allyl mustard oil, but acrinyl isothiocyanate, $C_6H_4OH \cdot CH_2O \cdot NCS$. The **sinalbin** contained in the seeds under the influence of myrosin and water decomposes forming that oil, sinapin acid sulphate, and glucose. The oil in question has a sharp taste. It decomposes on heating. It is insoluble in water, but readily in alcohol or ether. As the black seeds contain an excess of their glycoside and the white an excess of the ferment the combination of the two produces the strongest effect.

Some work by Prof. Greenish, however (*Pharm. J.*, i/1912, 203), shows that in all the samples of black mustard seed examined—both old and new—there was sufficient myrosin to decompose all the sinigrin present, and that properly preserved black mustard seeds retain their myrosin unimpaired for many years. Two samples examined contained sufficient myrosin to decompose a much larger quantity of sinigrin than the seeds themselves contained.

J. Gadamer has made a close study of these various constituents—see Schmidt, *Pharm. Chem.*, Vol. II, Sections 1 and 2.

The following definitions were given by the Food and Drug Administration of the U.S. Dept. of Agriculture:—Mustard seed as the seed of *Sinapis alba* L. (white mustard), *Brassica nigra* (L.) Koch (black mustard), *B. juncea* (L.) Cosson, or varieties or related species of the two latter. *Sinapis alba* contains no appreciable amount of volatile oil: contains not more than 5% of total ash and not more than 1.5% of ash insoluble in hydrochloric acid. *Brassica nigra* and *B. juncea* yield 0.6% of volatile mustard oil (calculated as allyl isothiocyanate): varieties and species of these two yield not less than 0.6% of volatile mustard oil of similar character and composition. These mustard seeds yield

not more than 5% of total ash, nor more than 1.5% of ash insoluble in hydrochloric acid. GROUND MUSTARD SEED, mustard meal; unbolted ground mustard seed, conforming to standards for mustard seed. MUSTARD CAKE is ground mustard seed minus a portion of the fixed oil. MUSTARD FLOUR, ground mustard, "mustard": the powder made from mustard seed with the hulls largely removed and with or without removal of portion of fixed oil: contains not more than 1.5% of starch, nor more than 6% of total ash. PREPARED MUSTARD: a paste composed of a mixture of ground mustard seed and/or mustard flour and/or mustard cake, with salt, a vinegar, with or without sugar and/or dextrose, spices or other condiments. In the fat-, salt-, and sugar-free solids, it contains not more than 24% of carbohydrates, not more than 12% of crude fibre, nor less than 5.6% of nitrogen, the carbohydrates being calculated as starch.—S.R.A., F.D. No. 2 Rev. 5, Nov. 1936.

Oleum Sinapis Expressum. *Detection of Linseed Oil in Mustard-seed Oil.* A micro-bromide test is described as follows: A drop of oil (0.04 to 0.06 g.) is spread on a microscope slide (which must be free from grease) by drawing it out with the narrow edge of a second slide along the whole length of the first slide. The film so obtained is exposed for 20 to 25 minutes in an atmosphere of bromine and then left in the air for a short time to remove excess of bromine. Linseed oil yields a hard, colourless, gritty film with wrinkled surface. Mustard-seed oil gives a soft, opaque and glossy film without tendency to wrinkle. The slide is now placed horizontally on the edge of a small rectangular trough and covered with a mixture of equal parts of ether and petroleum ether and the film stirred with a very thin glass rod and examined for the formation of a flocculent precipitate. Mustard-seed, cottonseed, arachis, kapok and mowrah oils give no precipitate. Linseed oil 5% and upwards in mustard-seed oil gives a precipitate.—S. Neogi, *Analyst*, 1935, 91.

Detection and Determination of Adulteration. The method depends on the presence of erucic acid, the lead salt of which is sparingly soluble in cold alcohol and separates with the solid fraction of the fatty acids. The figure determined is the percentage of iodine absorption of the solid fraction separated under standard conditions and expressed in terms of erucic acid.

From 500 to 510 mg. of the oil is accurately weighed in an Erlenmeyer flask and saponified with 5 ml. of alcoholic potash (40 ml. of aqueous potassium hydroxide solution of sp. gr. 1.5, 40 ml. of water and alcohol 95% to 1 litre) for 1 hour. The saponified solution is treated with 20 ml. of lead acetate solution (lead acetate 50 g., 96% acetic acid 5 ml., alcohol (80% v/v) to 1 litre), and 3 ml. of water and 1 ml. of 96% acetic acid, and heated under a reflux condenser until the lead salts are dissolved. The solution is cooled slowly to room temperature, kept in an incubator at 20° for 14 hours and is then transferred to a 3G/10 sintered glass crucible with the aid of alcohol 70% (cooled to 20°). The precipitate is washed with 12 ml. (in small portions) of the cooled alcohol previously used for rinsing the flask, and then dissolved in 20 ml. of a hot mixture of equal parts of alcohol 95% and acetic acid 96% and the warm solution and the crucible are washed into a 350 ml. bottle of Jena glass with 10 ml. of alcohol and acetic acid mixture. The iodine value of the lead salt solution is then determined by adding 20 ml. of fresh N/5 alcoholic iodine solution and 200 ml. of water, shaking, and setting aside in the dark for 1 hour and then titrating with N/10 thiosulphate. The "value" calculated is the percentage of iodine absorption in terms of erucic acid. 1 ml. of N/10 thiosulphate corresponds to 16.9 mg. of erucic acid. Examination of a number of authentic oils from various species of *Brassica* and of mixtures of these oils gave results between 42.8 and 49.7. Linseed, sesame, niger-seed and arachis oils all gave results in the neighbourhood of 2, while with castor oil the value found was about 0.2. Figures are also given showing the values obtained with various mixtures of genuine mustard-seed oil and other vegetable oils thus providing a method for the determination of the proportion of adulterant.—Sukumar Neogi, *Analyst*, 1936, 597.

Oleum Sinapis Volatile (B.P.C.). Contains not less than 92% w/w of $C_9H_{17}NCS$. Sp. gr., 1.014 to 1.025; n_{D20} , 1.525 to 1.530. Assayed by heating an alcoholic dilution under a reflux condenser on a water-bath for 30 minutes with N/10 silver nitrate and strong solution of ammonia, followed by adjustment to volume, filtration and titration of an aliquot part with N/10

ammonium thiocyanate. Oleum Sinapis Volatile, *U.S.P. XI*, is renamed Allylis Isothiocyanas in the *U.S.P. XII* and may be the natural or synthetic product. It contains not less than 93% w/v of C_3H_5NCS . Sp. gr. at 25° , 1.013 to 1.020; n_{D20° , 1.5275 to 1.5310. Distills completely between 148° and 154° , the first and last 10% of the distillate having almost the same sp. gr. as the original oil.

Determination of essential oil of mustard in black mustard.—Miesemaeker and Boivin, *J. pharm. Chim., Paris*, 1930, 122, 478.

Determination of Essential Oil in Mustard Flour. The glycosides are hydrolysed under standard conditions, the phosphate present is precipitated with $MgCO_3$ and NH_3 and the sulphate precipitated in the filtrate with benzidine; the washed benzidine sulphate is then dissolved in NaOH and back titrated with H_2SO_4 .—R. C. Terry and J. W. Corran, *Analyst*, 1939, 164-172.

SODIUM

Notes on other sodium salts are included under the corresponding acids (see Index).

Sodii Bicarbonas (B.P.). $NaHCO_3 = 84.00$. Contains from 99% to the equivalent of 101% of $NaHCO_3$. The *U.S.P. XII* substance, after drying over sulphuric acid, contains not less than 99% of $NaHCO_3$. 1 g. in 20 ml. of distilled water not above 15° should not contain sufficient carbonate to produce a red tint on adding 2 ml. of N/10 hydrochloric acid and 2 drops of phenolphthalein solution. Carbonate Acide de Sodium, *Fr. Cx.* 1937, by ignition to carbonate; contains 99.5% of the pure substance.

The B.P. Limit Test for Carbonate. The test for carbonate in sodium bicarbonate is not sensitive to less than about 4%, but the assay would condemn a sample, if dry, containing 2% of sodium carbonate.—W. H. Linnell, *Pharm. J.*, ii/1932, 531.

The pH of 1% sodium bicarbonate solution is raised from 8.37 to 8.60 by the addition of 2.05% of normal carbonate. In practice, owing to the limited accuracy of the official method, a considerably higher percentage would escape notice. The following is a more sensitive test:—1 g. $NaHCO_3$ is dissolved in CO_2 -free water, exactly 10 ml. of 0.01% phenolphthalein solution is added, and the solution diluted to 100 ml. in a Nessler glass. A comparison solution is prepared by diluting 5 to 10 ml. N/10 NaOH and exactly 0.3 ml. of the same phenolphthalein solution to 100 ml. in a second Nessler glass. The test solution must not be deeper than the comparison solution.—C. Morton, *Pharm. J.*, i/1933, 3.

2 g. of sodium bicarbonate is added to 15 ml. of a saturated solution of sodium chloride and allowed to stand for 2 minutes. Undissolved bicarbonate is filtered off and the filtrate is made up with CO_2 -free water to 25 ml. and treated with 0.1 ml. of 1% phenolphthalein solution. The colour of the liquid is then observed against a white background. The presence of 0.5% of sodium carbonate is shown by a distinct pink colour.—T. Sabolitschka, per *Quart. J. Pharm.*, 1939, 121.

Tabellæ Sodii Bicarbonatis (N.F. VII). Contain 92.5 to 107.5% of labelled amount of sodium bicarbonate, including all tolerances.

Sodii Carbonas (B.P.). $Na_2CO_3 \cdot 10H_2O = 286.15$. Contains from 99% to the equivalent of 102% of the pure substance. The substance of the *Fr. Cx.* 1937 loses not more than 63% on ignition to red heat and, by titration in boiling solution to phenolphthalein, contains not less than 37% of the anhydrous salt.

Sodii Carbonas Exsiccatus (B.P.). $\text{Na}_2\text{CO}_3=106.0$. Loses not more than 2% at 110° , and then contains not less than 99.5% of Na_2CO_3 .

Sodii Carbonas Monohydratus (U.S.P. XII). When dried to constant weight at 110° loses 10–15% and contains not less than 99.5% of Na_2CO_3 .

Sodii Chloras (B.P.C.). $\text{NaClO}_3=106.5$. Contains not less than 99% of NaClO_3 .

Sodii Fluoridum (B.P.C.). $\text{NaF}=42.00$. Contains not less than 90% of NaF . Assayed by titration at 80° of a solution in carbonate-free alkali, in the presence of sufficient neutral sodium chloride to saturate at end of titration, with N/10 potassium aluminium sulphate, using methyl red as indicator.

Sodii Hydroxidum (B.P. Add. I). $\text{NaOH}=40.00$. Contains not less than 95% of total alkali, calculated as NaOH , and not more than 2.5% of Na_2CO_3 ; assayed similarly to the potassium compound. Limit test for chlorides and sulphates are included. The U.S.P. XII substance assayed similarly to the potassium-compound, contains not less than 95% of total alkali as NaOH , of which not more than 3% is Na_2CO_3 .

Liquor Sodii Hydroxidi (B.P. Add. IV). Contains 3.4 to 3.7% w/v of total alkali as NaOH .

British Standard Density-Composition Tables for Aqueous Solutions of Caustic Soda (B.S.S. No. 824—1938), designed for use in conjunction with British Standard Density Hydrometers, give the concentration in g. of NaOH per 100 g. and in g. of NaOH per 1000 ml. corresponding to densities of 1 to 1.530 for each 5° over the range of 10° to 40° .

Detection and Determination of Sodium. Sodium may be detected and determined by means of dihydroxytartaric acid, $[(\text{HO})_2\text{C}(\text{COOH})_2]$. The reagent is used as a freshly prepared solution of its potassium salt prepared by neutralising until slightly pink a solution of 1 g. of the acid in 20 ml. of water containing 1 drop of phenolphthalein solution and cooled in ice, with N/1 KOH , also cooled in ice. The solution should not be kept for more than 1 day. The solution to be tested is cooled below 5° and mixed with an equal volume of the reagent solution. The mixture is allowed to stand below 5° . In the presence of sodium a white crystalline precipitate forms in from 1 minute to several hours according to the proportion present. The test solution should be neutral and contain no other metals except magnesium and the alkali metals. For determining sodium the reagent is prepared by dissolving 1 g. of dihydroxytartaric acid in 5 ml. of water, adding 35 ml. of ice-cold water and 5.5 ml. of M/1 potassium carbonate solution. To 5 ml. of the sodium solution, containing 1.0 to 1.5% of sodium as the chloride, sulphate or nitrate, add the whole of the above quantity of reagent with stirring, maintaining a temperature of 5° . Allow to stand for 5 hours at this temperature, collect the precipitate, wash with 10 ml. of ice-cold water and place precipitate and paper in acidified permanganate solution consisting of 100 ml. of N/10 potassium permanganate, 100 ml. of 5N sulphuric acid, 100 ml. of 6.3N phosphoric acid and 2 ml. of a freshly prepared 0.05% solution of ammonium metavanadate in water acidified with dilute sulphuric acid. Allow to stand at room temperature for 20 minutes, heat to 50° and titrate with N/10 oxalic acid. Each ml. of permanganate used is equivalent to 0.000767 g. of Na. Add to the result 0.0051 g. of Na to correct for the slight solubility of sodium dihydroxytartrate. Alternatively the sodium may be determined gravimetrically by dissolving the precipitate in sulphuric acid, evaporating to dryness and igniting to Na_2SO_4 .

Sodium may be detected and determined by means of zinc uranyl acetate. The solution of the reagent is obtained by mixing a solution of 10 g. of uranyl acetate in 6 g. of acetic acid (30%) and 65 g. of hot water with a solution of 30 g.

of zinc acetate in 3 g. of acetic acid (30%) and 65 g. of hot water. The mixed liquids are maintained at 19° to 21° for several hours and any crystals of the triple salt, $\text{NaZn}(\text{UO}_2)_2 \cdot (\text{C}_2\text{H}_3\text{O}_2)_6 \cdot 6\text{H}_2\text{O}$, are removed by filtration. *Detection of sodium*.—The test solution is neutralised and mixed with an equal volume of the reagent. In the presence of sodium yellow crystals of sodium zinc uranyl acetate are produced. *Determination of sodium*.—To 10 ml. of the neutral solution containing not more than 0.08 g. of sodium is added 100 ml. of the reagent, and the mixture is allowed to stand at 19° to 21° for 30 to 45 minutes with occasional stirring. The crystals are collected, washed with five successive quantities each of 2 ml. of the reagent and then with five successive quantities each of 2 ml. of alcohol saturated at 20° with sodium zinc uranyl acetate. The precipitate is washed finally with ether, dried at 40° for 10 to 15 minutes and weighed. Each gramme of precipitate is equivalent to 0.01495 g. of Na.

STRAMONIUM

Stramonium (B.P.). Contains not more than 2% of foreign organic matter, not more than 20% of stems, not more than 1% of stems greater than 4 mm. in width, and not less than 0.25% of alkaloids of stramonium, calculated as hyoscyamine. Ash limit, 20%. Acid-insoluble ash limit, 4%. Assayed by the B.P. process for *Belladonnæ Folium*.

Stramonium, *U.S.P. XII*, yields not less than 0.25% of alkaloids, not more than 4% of acid-insoluble ash and contains not more than 3% of stems over 8 mm. in diameter. Assayed by the process described for *Hyoscyamus, U.S.P. XII*. *Folium Stramonii, P. Helv. V*, contains not less than 0.2% of alkaloid and may yield up to 21% of ash.

Tentative methods for the determination of alkaloids of stramonium leaf in ointments are described in *Methods of Analysis (A.O.A.C., 1940, 599)*.

STROPHANTHUS

Strophanthus (B.P.). From *Strophanthus kombé*. Foreign organic matter, not more than 2%. Ash, not more than 5%. *Strophanthus, N.F. VII*, assayed on a tincture prepared by the process for Tincture of *Strophanthus, N.F. VII*, in each gramme possesses a potency equivalent to not less than 55.0 mg. of standard ouabain. *Semen Strophanthi, P.G. VI*, consists of the seeds of *Strophanthus gratus* (Wallich and Hooker) Franchet, and contains not less than 4% of anhydrous *g-strophanthin*; assayed by the process given:—Reflux 7 g. of drug with 70 g. of absolute alcohol for 1 hour, adjust to weight and filter. Take 51.5 g. of filtrate (= 5 g. of drug) and distil until 1 or 2 g. remain, add absolute alcohol to 5 g. and then 30 g. of petroleum ether. If there is no deposit within 1 hour, shake forcibly with 2 or 3 drops of alcohol. Decant the alcohol-petroleum ether solution and wash twice with 5 g. of petroleum ether. Warm the precipitate on a water-bath with 10 ml. of water, add and warm with 5 or 6 drops of basic lead acetate solution, filter and wash four times with 5 g. of water. Pass hydrogen sulphide through the warm filtrate and after 2 hours filter, washing 3 times with 5 g. of water. Evaporate the filtrate

to 5 g.; transfer to a cylinder with 2 portions of 1 g. of water and evaporate to 2 to 2.5 g. Allow to crystallise for 24 hours and finally dry at 105° to 110°. Semen *Strophanthi*, *P. Helv. V*, is the seed of *Strophanthus kombé* Oliver.

The geographical range of *S. kombé* is limited. It might be well to order the use of *S. hispidus* instead—it is more easily obtained and is the only other species giving the green colour with sulphuric acid.—E. M. Holmes, *Pharm. J.*, i/1919, 33.

Recent specimens of *S. kombé* are much mixed with *S. Courmontii*, whilst samples of *S. hispidus* can no longer be found unadulterated in commerce, and are entirely, or in large proportion, seeds of *S. sarmentosus*. A useful table gives the characters of *Strophanthus* species found in commercial samples.—F. J. Mathieson, per *Quart. J. Pharm.*, 1928, 260, 262.

Four colour tests are recommended for the identification of the seeds of various species of *Strophanthus*.—E. M. Smelt, *Quart. J. Pharm.*, 1933, 467.

Tinctura Strophanthi (B.P.). Tincture of strophanthus is compared with a standard tincture of strophanthus by one of the biological methods described under *Digitalis Pulverata*, and is diluted to be of the same potency as the standard tincture. This standard is equivalent to a 0.42% solution of the international standard ouabain (crystalline strophanthin-g), or to a 0.33% solution of anhydrous ouabain as determined by a biological comparison made by the frog method. Tinctura *Strophanthi*, *P. Helv. V*, contains from 0.19 to 0.21% of strophanthin determined by conversion to strophanthidin and multiplying by the factor 2.158.

Seeds of *Strophanthus Eminii*. The results now accumulated indicate that the seeds of this species of strophanthus are similar in their pharmacological action to those of *S. kombé*, that the tincture made from them presents no difficulties in biological assay, and that the mixture of glycosidal principles obtained from them is similar in chemical composition and in therapeutic effects to the strophanthin obtained from the seeds of *S. kombé*.—British Pharmacopœia Commission, *Quart. J. Pharm.*, 1935, 61.

***Strophanthus dichotomus* DC.** contains a powerful cardiac poison. The tincture can be differentiated from tinctures prepared from the seven species of *Strophanthus* examined by Smelt (*supra*) by the following tests applied to 1 ml. portions of the residue obtained by evaporation on a water-bath. Sulphuric acid 75%—brownish violet in 10 to 15 minutes; phenol and hydrochloric acid—pink to cloudy bluish-green; resorcinol and hydrochloric acid—pink-brown to red-orange.—A. H. Millard, *Pharm. J.*, ii/1936, 147.

Preparation of *Strophanthin-E*. The crushed seeds of *S. Eminii* were freed from fat by light petroleum and extracted by percolation with alcohol (90%) at laboratory temperature. The percolate was concentrated under reduced pressure and treated with a slight excess of basic lead acetate. After filtration the solution was freed from lead by excess of hydrogen sulphide. The solution was saturated with ammonium sulphate, and the sticky precipitate which formed was extracted with alcohol. The alcoholic solution was either neutralised with a little sodium hydroxide and precipitated with ether or precipitated without neutralisation. The strophanthin was dried at 100° *in vacuo*. The yield is from 5 to 7% of the fat-free seeds, and is similar to that obtained from *S. kombé*.—I. D. Lamb and S. Smith, *Quart. J. Pharm.*, 1935, 71.

Chemical Assay. Haycock's Method. The powdered seeds (20 g.) are freed from oil with petroleum ether and exhausted with alcohol 70%. This tincture is evaporated at a low temperature, dissolved in 100 ml. of water, filtered, 3.2 ml. of sulphuric acid (25%) added, then shaken out thrice with 20 ml. of ether. The aqueous acid solution is warmed for 1 hour at not exceeding 75°. This decomposes the strophanthin present into strophanthidin and strophanthobiose methyl ether. It is then cooled and shaken out with 10 ml. of chloroform. This is evaporated to a low bulk, allowed to crystallise out and dried below 65°. The result divided by the factor 0.365 gives the amount of

strophanthin present. Various samples of the seed by this method gave 3.1 to 4.57% strophanthin. A standard of 0.1% w/v strophanthin is suggested.—J. Haycock, *Pharm. J.*, i/1911, 553.

FROMME'S 1910 ASSAY METHOD. Consists in first extracting with absolute alcohol under a reflux, evaporating and defatting the extract. This is boiled with water and a few drops of lead acetate solution and then filtered, using diatomite. The glycoside is next decomposed by heating with hydrochloric acid, and finally the strophanthidin is thoroughly extracted with chloroform and weighed. This multiplied by 2.187 gives the weight of strophanthin represented. A similar process is used for the tincture.—W. Kroseberg, *Pharm. J.*, i/1914, 590.

Strophanthinum (B.P.). Adjusted by admixture with lactose to possess an activity equal to 40% of that of anhydrous ouabain. Loss on drying in a vacuum desiccator over sulphuric acid, not more than 3%. Ash, not more than 1%. Samples are compared with a standard preparation of strophanthin the potency of which has been accurately determined in relation to anhydrous ouabain. The method used for assay is one of those described under *Digitalis Pulverata*. *Strophanthinum, U.S.P. XII*, possesses a potency per mg. equivalent to 0.5 mg. of *U.S.P.* ouabain reference standard. It is assayed by the cat method described for *Tinctura Digitalis, U.S.P. XII*.

Wokes (*Quart. J. Pharm.*, 1928, 513) examined a series of commercial samples, testing them in comparison with ouabain, and found them to vary from 25 to 60% of the potency of ouabain.

Distinction between Strophanthin and Ouabain. Strophanthin is soluble in water 1 in 40 to 43 at 15°. The aqueous solution of this glycoside, unlike that of ouabain, gives a persistent froth on agitation.

The following distinguishing colour test has been proposed: 5 ml. of conc. hydrochloric acid, a few crystals of resorcinol and a trace of the glycoside are warmed to 60° or 70°. Ouabain gives no coloration, while strophanthin gives a rose colour.—*J. chem. Soc. Abstr.*, ii/1921, 601.

Hispidus strophanthin, like *kombé* strophanthin, is a mixture of two glycosides.—*Brit. chem. Abstr.*, Dec., 1928, 1376.

Strophanthin-G (Ouabain). This is the official strophanthin of the German Pharmacopœia and is included in the *U.S.P. XII*. It is referred to in the *B.P.* as a standard for biological assays. It is not an official preparation in the Pharmacopœia because supplies for therapeutic use are believed to be insufficient. It is a crystalline substance of constant composition except that it may contain different amounts of water of crystallisation. The international standard ouabain contains 20% of water of crystallisation. On crystallisation at the ordinary temperature $C_{21}H_{44}O_{11} \cdot 9H_2O$ is obtained, whereas if the temperature is 30° or 60° the crystals contain four and three molecules of water respectively. Ouabainum, *U.S.P. XII*, has the formula, $C_{21}H_{44}O_{11} \cdot 8H_2O = 728.77$. M.p., 186° to 189°; α_D determined on a 1% w/v aqueous solution, -31° to -32.5°; loss on drying at 130°, 18 to 22%. Complies with tests for absence of alkaloids.

Spinal rather than anæsthetised cats should be used for the assay of cardiac glycosides. In the assay of strophanthin by the cat method, the grouping of the figures is improved if a non-volatile anæsthetic be used instead of ether, and still further improved by using spinal animals. The interval between the preparation of the cat and the infusion should be about 4 hours.—A. D. MacDonald, *Quart. J. Pharm.*, 1934, 182.

SULPHANILAMIDUM

Sulphanilamidum (B.P. Add. IV and VI). $C_6H_8O_2N_2S = 172.1$. Contains 99.0 to 100.5% of the pure compound, calculated with reference to the dried substance. Loss in *vacuo* at 100°, not

more than 1%. Dissolves completely in 10 parts of dilute hydrochloric acid, and in 5 parts of sodium hydroxide solution (10%). No ammonium salts should be detected on boiling with sodium hydroxide solution. Assayed by formation of the di-bromo substitution product by interaction with excess N/10 bromine solution in acid mixture during 15 minutes, interaction of the excess bromine with potassium iodide and back titration with N/10 sodium thiosulphate; 1 ml. of N/10 bromine is equivalent to 0.0043 g. $C_6H_8O_2N_2S$. Sulfanilamidum, *U.S.P. XII*, loses not more than 0.5% at 100°, and then contains not less than 99% of $C_6H_8O_2N_2S$. M.p., 164.5° to 166.5°. Assayed by dissolving in hydrochloric acid and water, cooling to 15°, adding crushed ice and slowly titrating with M/10 sodium nitrite whilst stirring vigorously, until the titration mixture after standing for 1 minute gives an immediate blue colour when streaked on a smear of starch iodide paste. Ash, not more than 0.1%.

Alternative Assay Methods.—The following methods are suggested:—

(a) As the di-bromo substitution product. 30 to 80 mg. is dissolved in acid in a flask, the stopper of which is surrounded by a cup, the solution is made alkaline with sodium hydroxide, diluted to 50 ml., treated with 0.5 g. of potassium bromide and then with N/10 potassium bromate run in from a burette until there is a 10 to 30% excess. 10 ml. of hydrochloric acid is added and the flask closed and placed in the dark for 5 minutes. It is then cooled, a solution of 3 g. of potassium iodide in 10 ml. of water is run in from the cup, the mixture is diluted to about 300 ml. and titrated with N/10 thiosulphate. 1 ml. of potassium bromate solution is equivalent to 4.304 mg. of sulphanilamide. Errors varied from +0.3 to +0.8%.

(b) *Direct titration.* Sulphanilamide in solution in 5-10% sulphuric acid may also be determined by direct titration with potassium bromate solution after adding 1 g. of potassium bromide. The end-point is indicated by the appearance of a yellow colour. The results are somewhat low.

(c) *Hydrolysis of the Sulphonamide Group.* 20 to 200 mg. is boiled for 1 hour with 5 ml. of 70% sulphuric acid beneath a reflux condenser with ground glass connections. The condenser is rinsed into the flask the contents of which are then diluted to 50 to 60 ml. A few drops of methyl red solution and a little pumice are added and the liquid distilled into a receiver containing a measured volume of N/50 to N/10 hydrochloric acid, according to the weight of sample being tested. When the air in the apparatus has been replaced by water vapour, 10% solution of sodium hydroxide (ammonia-free) is added from a tap funnel until there is an excess of 0.2 to 1 ml. over that required for neutralisation. When two-thirds of the liquid has been distilled, the condenser is rinsed into the receiver, the contents of the latter are boiled with pumice, cooled and titrated with N/50 or N/10 sodium hydroxide. 1 ml. of N/50 acid is equivalent to 8.4428 mg. of sulphanilamide. The error varies from 0 to +1.2%.—E. Schulek and I. Boldizsar, *Z. anal. Chem.*, 1937, 108, 396.

The sulphur may be determined by the following process:—Introduce a weighed quantity of the sample (about 0.15 g.) into a flask containing 2 g. of potassium permanganate, 0.5 g. of potassium hydroxide and 30 ml. of water, and boil the mixture under a reflux condenser for three hours. The contents of the flask are then carefully acidified with hydrochloric acid and boiled until a clear solution is obtained, then diluted with water and the sulphate determined in the usual way by precipitation with barium chloride.—N. L. Allport, *Quart. J. Pharm.*, 1936, 560.

Two rapid and accurate methods are described for the assay of sulphanilamide. The first is a determination of the crystallising point and the second, the diazotisation method performed potentiometrically.—R. W. Towne and R. M. Hitchens, *J. Amer. pharm. Ass.*, 1939, 585.

About 0.5 g. of sulphanilamide is treated with 20 ml. of concentrated hydrochloric acid in a beaker, and the mixture brought to the boil. While boiling gently, 5 ml. of hydrogen peroxide (30%) is dropped in during a period of ten

minutes. The solution is boiled for two minutes and filtered, and the sulphate in the filtrate determined by precipitation with barium chloride.—G. v. Mikó, *Pharm. Zentralh.*, 1939, 80, 198.

Microscopical Identification. Description of technique and appearance of crystals.—C. Van Zyp, per *Analyst*, 1938, 5, 511.

A table of the aqueous solubilities of sulphanilamide over a temperature range of 23° to 50° is given.—R. H. Keirle and J. M. Sayward, *J. Amer. chem. Soc.*, 1942, 2465.

Tabellæ Sulfanilamidi (U.S.P. XII). Contain 95 to 105% of the labelled amount of $C_6H_5N_2O_2S$, including all tolerances. A weighed quantity of powdered tablets is assayed by titration with M/10 sodium nitrite as described for sulphanilamide.

Determination in Tablets. Weigh 20 tablets, transfer them to a clean mortar, and powder. Weigh 0.4 g. of the powder and transfer it to a 25 ml. glass-stoppered graduated cylinder. Add 10 ml. of an ice-cold, filtered, saturated solution of sulphanilamide. Shake well. Filter through a Jena glass filter. Wash any residue in the cylinder and the material on the filter with a few drops of ice-cold distilled water to displace any sulphanilamide solution. Completely extract the residue in the cylinder and the material on the filter with 80 to 100 ml. of hot alcohol. Wash the funnel tip and any exposed edges with a few ml. of hot alcohol. Collect the alcohol and washings in a tared 250-ml. beaker. Carefully evaporate the alcohol on a steam-bath. Dry in the oven at 80° to constant weight.—W. E. Housinger and R. E. Schoetgow, *J. Amer. pharm. Ass., Sci. Edn.*, 1940, 133.

A tentative method for the determination of sulphanilamide is described in *Methods of Analysis (A.O.A.C., 1940, 614)*. The sample containing about 0.5 g. of sulphanilamide is placed on a filter and the soluble portion washed into a flask with about 25 ml. of acetone. The acetone is removed by warming to 70° and 10 to 12 ml. of 75% v/v sulphuric acid added. The solution is slowly refluxed for thirty minutes, the condenser washed down with water, the solution diluted to about 100 ml. with water, and an excess of 50% alkali added. The solution is distilled, the ammonia in the distillate collected in an excess of N/10 sulphuric acid and back titrated with N/10 sodium hydroxide, using methyl red as indicator. 1 ml. of N/10 sulphuric acid is equivalent to 0.01722 g. of sulphanilamide.

Sulphacetamidum (B.P.C. Supp. III). $C_8H_{10}O_3N_2S = 214.1$. Loses not more than 0.5% on drying at 100°, and then contains 99.5 to 100.5% of $C_8H_{10}O_3N_2S$. M.p., 181° to 183°. Ash, not more than 0.1%. Assayed by titration at a temperature below 5° of the acidified solution with M/10 sodium nitrite, using freshly prepared starch potassium iodide paper as external indicator. 1 ml. M/10 sodium nitrite is equivalent to 0.02141 g. of $C_8H_{10}O_3N_2S$.

Sulphapyridina (B.P.C. Supp. III). $C_{11}H_{11}O_2N_3S = 249.2$. Determined by titration with M/10 sodium nitrite at a low temperature, contains 99 to 100.6% of the pure substance calculated on the dried substance. Loss at 100°, not more than 0.5%. M.p., 191° to 193°. Sulfapyridinum, *U.S.P. XII*, when dried at 100°, contains not less than 99% $C_{11}H_{11}N_3O_2S$. Ash, not more than 0.1%; 1 g. forms a clear, colourless solution in approximately N/20 sodium hydroxide. Sulfapyridinum Sodicum Sterile, *U.S.P. XII*, loses not more than 7% at 105° and then contains not less than 99% $C_{11}H_{11}N_3O_2SNa$. Complies with the sterility tests for solids, *U.S.P. XII*.

Tabellæ Sulfapyridini (U.S.P. XII). Contain 95 to 105% of the labelled amount of $C_{11}H_{11}N_3O_2S$, including all tolerances. Assayed by titrating a weighed quantity of powdered tablets with M/10 sodium nitrite as described for sulphanilamide.

Test for Sensitivity of Pneumococci to Sulphapyridine. Pneumococci differ profoundly in their sensitivity to the sulphonamides; resistant strains occur in nature; sensitive strains may become resistant when they are exposed to the drug; resistant strains are probably permanently resistant. A rapid qualitative test is as follows: each of four mice is inoculated intraperitoneally with 0.2 ml. of 10% sulphapyridine suspended in 20% acacia. Fresh sputum (or empyema pus) obtained from the patient is made grossly homogeneous and liquid by mixing with a minimum necessary amount of sterile saline solution. Within the first two hours after treatment the four treated and in addition three untreated mice are alternately inoculated with the sputum mixture, as large a volume as possible (up to 1 ml.) being used for each mouse. At various intervals thereafter peritoneal exudate is removed from each mouse and examined rapidly to determine the number and morphology of the pneumococci. The test is read when growth of the pneumococci in the untreated mice has become unquestionable, and at no earlier time. If, at this time, the treated mice show no increase in the number of pneumococci, or if there has been scanty growth with a preponderance of atypical forms, the strain is called sensitive; if smears of treated and control mice are virtually indistinguishable, the strain is called resistant. The test requires an average of 18 hours for completion and has a sharp end-point.—F. J. Moore *et al.*, *J. Amer. med. Ass.*, ii/1941, 437.

Sulphathiazolum (B.P.C. Supp. III). $C_9H_9O_2N_3S_2 = 255.2$. Assayed similarly to sulphapyridine it contains 99.4 to 100.6% of $C_9H_9O_2N_3S_2$. M.p., 202° to 203° . Loss at 100° , not more than 0.5%. Ash, not more than 0.05%. Sulfathiazolum, *U.S.P. XII*, contains not less than 99% $C_9H_9N_3O_2S_2$ after drying at 100° . M.p., 200° to 204° ; ash, not more than 0.1%. Complies with tests for acidity and solution in sodium hydroxide solution. Assayed by titration with M/10 sodium nitrite.

The colorimetric method of estimation of sulphapyridine (Marshall, *Science*, 1938, 88, 85) is applicable to sulphathiazole. The following test distinguishes between sulphathiazole and sulphapyridine. To a solution of the sodium salt add a solution of cupric sulphate, when sulphathiazole produces a purple and sulphapyridine an apple-green precipitate.—W. A. Lott and F. H. Bergheim, *J. Amer. chem. Soc.*, 1939, 3593.

The method depends upon the production of a stable, easily soluble, violet component by coupling of sulphathiazole with 1-sulphomethylaminonaphthalein-8-sulphonic acid and the determination is carried out colorimetrically. Details are given of the application of the method to blood, urine and milk determinations.—J. Druey and G. Oesterheld, *Analyst*, 1942, 331.

Tabellæ Sulfathiazoli (U.S.P. XII). Contain 95 to 105% of the labelled amount of $C_9H_9N_3O_2S_2$, including all tolerances. Assayed by the process described for sulphanilamide using M/10 sodium nitrite.

Sulphadiazine, sulphapyrimidine or 2-sulphanil-aminopyrimidine, melts at 255° to 256° with decomposition. It is soluble in water at 37° , 12.3 mg. per cent. The acetyl derivative is approximately identical, with slightly higher m.p. and solubility.—*Amer. Prof. Pharm.*, 1941, 365.

Sulphaguanidine, sulphanilylguanidine, is a fine, white, tasteless powder, which crystallises in water as the monohydrate. It melts at 142.5° to 143.5° . The anhydrous drug softens at 168° to 178° and melts at 189° to 190° . Soluble in boiling water 10%, boiling alcohol (95%) 5%, in dilute mineral acids; insoluble in dilute alkalis. A saturated solution in water at 25° has pH 6.9. Chemically it has two possible formulas, thought to be resonance isomers:— α -sulphanilylguanidine is $NH_2 \cdot C_6H_4 \cdot SO_2 \cdot NH \cdot C : NH \cdot NH_2$, and β -sulphanilylguanidine is $NH_2 \cdot C_6H_4 \cdot SO_2 \cdot NH : C(NH_2)_2$.—*Amer. Prof. Pharm.*, 1941, 361.

Sulphathiophene, 2-sulphanilamido-thiophene, has been prepared as white needle-like crystals, m.p. 156.5° to 157.5° , soluble in hot water, methyl alcohol, ethyl alcohol, 1% aqueous sodium hydroxide, 1% aqueous hydrochloric acid and slightly in ether.—R. W. Bast and C. F. Starnes, *J. Amer. chem. Soc.*, 1941, 1885.

SULPHONAL

Sulphonal (B.P.). $(\text{CH}_3)_2\text{C}(\text{SO}_2\text{C}_2\text{H}_5)_2 = 228.2$. M.p., 125° to 127° ; ash, not more than 0.05%. A test for readily oxidisable substances is included. The *N.F. VII* substance melts between 124° and 126° and loses not more than 1% when dried over sulphuric acid. The *Fr. Cx.* limits the ash to 0.1% and includes tests for heavy metals, barium and chloride.

Methylsulphonal (B.P.). $(\text{CH}_3)(\text{C}_2\text{H}_5)\text{C}(\text{SO}_2\cdot\text{C}_2\text{H}_5)_2 = 242.3$. M.p., 76° to 78° ; ash, not more than 0.05%. Complies with a test for readily oxidisable substances. Sulfonethylmethanum, *N.F. VII*, melts between 74° and 76° .

A tentative method for the determination of sulphonal and methyl sulphonal is described in *Methods of Analysis (A.O.A.C., 1940, 581)*.

SULPHUR

Sulphur Præcipitatum (B.P.). S = 32.06. Residue on ignition, not more than 0.5%. Consists, when examined microscopically, of grouped amorphous globules without crystalline particles. The *U.S.P. XII* substance, dried over sulphuric acid, contains not less than 99.5% of S. Assayed by oxidation of a solution in potassium hydroxide with hydrogen peroxide, and precipitation as barium sulphate, subtracting the weight obtained in a blank determination on the reagents used. Residue on ignition, not more than 0.3%.

Sulphur Sublimatum (B.P.). Residue on ignition, not more than 0.25%. Consists, when examined microscopically, chiefly of almost opaque, rounded, amorphous particles or aggregates, occasionally associated with semi-crystalline masses. The *U.S.P. XII* substance, dried to constant weight over sulphuric acid and assayed by precipitation as barium sulphate, contains not less than 99.5% of S. Residue on ignition, not more than 0.5%.

Detection of Free Sulphur. Free sulphur can be detected by using benzylimido-di-(*p*-methoxyphenyl)-methane, $(\text{CH}_3\cdot\text{O}\cdot\text{C}_6\text{H}_4)_2\text{C}:\text{N}\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4$. The reagent is used as the solid. The substance to be tested is well ground with the reagent and a portion of the mixture is placed in a micro test-tube and heated for 5 minutes in an oil-bath at 210° . The tube is then removed from the bath and 2 to 3 drops of benzene are added. If sulphur was originally present the benzene is coloured blue owing to the formation of *pp'*-dianisylthioketone. On adding a small crystal of mercuric chloride, the blue colour slowly fades and the crystal acquires a red or orange colour.

Assay of Preparations. The sample to be assayed, containing 0.1 g. of S, is weighed accurately into a 175 ml. conical flask and 50 ml. of a solution containing 40 g. of potassium cyanide A.R., 90 ml. of triethanolamine and water to 1000 ml., is added together with 1 g. of soft paraffin. A little pumice is added to prevent superheating, and the mixture is vigorously boiled for $\frac{1}{2}$ hour under a reflux condenser. The liquid is cooled, treated with 10 ml. formaldehyde solution and acidified with dilute nitric acid, and 50 ml. of N/10 silver nitrate is added. The mixture is decolorised if necessary with charcoal, filtered, the residue washed, and the filtrate titrated with N/10 ammonium thiocyanate, using ferric alum as indicator. A blank is carried through on 10 ml. of the reagent. Each ml. of N/10 AgNO_3 is equivalent to 0.003206 g. of S.—N. L. Allport, *Quart. J. Pharm.*, 1933, 431.

Sulphur in flowers of sulphur, sulphur ointment, confection of sulphur, sulphur tablets and compound liquorice powder may be determined by boiling the material (equivalent to about 0.1 g. of sulphur) in a conical flask attached to a reflux condenser with 2 g. of crystalline sodium sulphite and 30 to 40 ml. of water until all the sulphur has dissolved. The addition of 1 g. of soft paraffin assists solution. Cool, pour off from the paraffin and wash the residue with water, add 10 ml. of solution of formaldehyde and 10 ml. of 20% acetic acid to remove the excess of sulphite, and titrate the thiosulphate formed in the solution with N/10 iodine, using starch as indicator; 1 ml. of N/10 iodine is equivalent to 3.206 mg. of sulphur.—H. R. Fleck and A. M. Ward, *Quart. J. Pharm.*, 1934, 179.

Sulphur Ointment. About 0.5 g. is weighed in a 50 ml. flask of resistant glass, 2 ml. of 20% w/v sodium hydroxide solution is added and the flask heated on a small hole of the water-bath. From time to time the flask is gently rotated so as to wash down any particles of sulphur from the sides which if necessary may be finally rinsed with a fine jet of hot water. After $\frac{1}{2}$ to 1 hour the sulphur dissolves completely, both oily and aqueous layers being clear. 5 ml. of 20 vol. hydrogen peroxide is added, and the flask again heated on the water-bath for 15 minutes, a small funnel being placed in the neck of the flask to avoid loss by effervescence. About 20 ml. of hot water is added, and the liquid cautiously acidified with dilute (1 : 3) hydrochloric acid, care being taken to avoid a large excess (4 to 5 ml. is required). The liquid is then filtered through a wet filter-paper into a beaker and the flask washed thoroughly with several quantities of hot water, the washings being passed through the same filter. Sulphate in the filtrate is determined in the usual way by precipitation with barium chloride. A blank test is made with the reagents and the results deducted. The method can be applied to confection of sulphur (using about 0.1 g.) and sulphur lozenge (about 0.15 g., previously powdered). It is also applicable to compound liquorice powder, but the sample after being weighed in the flask is preferably moistened with 1 ml. of water which is allowed to soak in before adding the alkali.—A. N. Leather, *Analyst*, 1936, 335.

The following assay is recommended by the Sub-Committee on the Assay of Galenicals of the Committee on Pharmaceutical Chemistry:—Boil about 1 g., accurately weighed, with a solution of 2 g. of crystalline sodium sulphite in 40 ml. of water in a 250-ml. conical flask under a reflux condenser until the sulphur is completely dissolved. Cool, decant the aqueous solution, wash the residue of fat with hot water; cool, decant and repeat the washing. Add the washings to the solution; add 10 ml. of solution of formaldehyde and 6 ml. of acetic acid; dilute to 150 ml. and titrate with N/10 iodine, using mucilage of starch as indicator. Each ml. of N/10 iodine is equivalent to 0.003206 g. of S. Limits of 9.5 to 10.5% of S are suggested.—(*British Pharmacopæia Commission Report*, No. 11, May 1939.)

Mustard Gas, dichlorodiethyl sulphide, $S(CH_2CH_2Cl)_2$, was first used at Armentières by the Germans in 1917 and is generally considered to be the most powerful nuisance gas on account of its prolonged delayed action and owing to its odour frequently passing unnoticed. It is a heavy oily liquid, colourless when pure, but when impure the colour varies from a pale yellow to a tarry black. The sp. gr. is 1.28 at 15°, so that it sinks in water, but on wet surfaces it spreads, forming an iridescent film, from which vapour is given off. It has a m.p. of 14.4° and readily supercools, and the freezing-point may be depressed, if necessary, by mixing with organic solvents. The b.p. is 217°, with decomposition. It is only slightly soluble in water, but is almost miscible with most organic solvents other than mineral oils, in which it is not so soluble. It is one of the most stable of war gases and is only slowly hydrolysed by cold water, though it is readily attacked by most oxidising agents, such as bleaching powder, potassium permanganate and chloramine-T, and these are employed for its destruction.

Detection. Mustard gas reacts with many alkaloidal reagents, yielding a turbidity of colloidal gold with 0.1% aqueous gold chloride solution, and precipitates with potassium tri-iodide, potassium mercury iodide and potassium bismuth iodide. It forms a di- β -naphthyl ether with a 1% solution of β -naphthol in N/10 50/50 aqueous alcoholic alkali forming a white turbidity, which becomes more obvious on warming. With sodium iodoplatinate solution iodine is liberated and this can be detected by the addition of starch solution, but the official method, which has now been adopted and which is known as the S.D. test, is dependent on the formation of acid which turns Congo red paper blue.

Sulphuretted Hydrogen in Industry.

This gas is formed when organic matter containing sulphur decomposes. It causes deaths in sewers, occurs in mines, and is a danger in certain chemical industries, especially gas, coke and tar works and petroleum refineries. It is colourless and has an odour of bad eggs by which it is readily detected, but the sense of smell is rapidly paralysed and lost after 2 to 15 minutes exposure at a concentration of 1 in 10,000. If concentrated it may resemble carbon monoxide in its rapidity of action, the subject appearing to drop almost instantaneously and it is considered one of the most toxic of gases. In concentrations of 1 in 1000 or higher it is nearly as toxic as hydrogen cyanide. 1 in 2000 is very dangerous if inhaled for 15 to 30 minutes and causes severe irritation of the eyes and respiratory tract with risk of pneumonia or serious injury to lungs which may prove fatal. 1 in 5000 is dangerous if inhaled for 1 hour, the eyes being affected after 6 to 8 minutes. 1 in 10,000 causes the eyes and respiratory tract to be affected after exposure for 1 hour.

Treatment. Prompt removal from the contaminated area, followed by artificial respiration, if necessary with administration of oxygen to which 5 to 7% of carbon dioxide has been added. The patient must be kept warm.

Detection and Determination. Hydrogen sulphide is most readily detected by means of lead acetate paper. Filter paper is impregnated with a 10% solution of lead acetate in 5% acetic acid and dried in a hydrogen sulphide-free atmosphere. The outer portions of the paper are discarded and a known volume of the suspected air is drawn through the filter paper by means of a pump or an aspirator, the colour varying from a yellowish-brown to a dark brown or black according to the quantity of gas present. The colour developed may be compared with those given in official standard charts. (*Toxic Gases in Industry*, No. 1, D.S.I.R.)

Sulphuris Chloridum (B.P.C.). S_2Cl_2 = 135.0. Sp. gr., about 1.70. B.pt., about 138°. Solidifying-point, about -80°.

Sulphuris Iodidum (B.P.C.). Contains not less than 70% of I. Assayed by titration of a triturate with potassium iodide solution, with N/10 sodium thiosulphate.

Calx Sulphurata (B.P.C.). Contains not less than 50% of CaS. Assayed by the *B.P.C.* process:—1 g. mixed with 10 ml. of water, 25 ml. of copper sulphate solution, and 10 ml. of dilute hydrochloric acid is warmed on a water-bath for 15 minutes, cooled and diluted to 100 ml. 25 ml. of the filtered mixture (the first 25 ml. is rejected) with 1 g. of potassium iodide is titrated with N/10 sodium thiosulphate, using starch mucilage as indicator; a blank experiment is performed.

Calcium sulfuraturn solutum, *P. Helv. V* (Soluté de Vlemingkx), contains 6% *w/v* of polysulphide sulphur. *Assay:* Boil for 2 minutes in a 100 ml. wide-mouthed flask 60 ml. of water with 1 g. of boric acid and a few pieces of porous pot. Add rapidly and cautiously 0.2 g. of potassium cyanide and then 1 ml. of the sulphur solution, and boil for 10 minutes. After cooling, transfer to a 100 ml. graduated flask, and add sufficient water to make 100 ml. Take 50 ml. of this solution, acidify with 1 or 2 ml. of concentrated hydrochloric acid and add bromine water until a yellow colour persists in the solution. Remove the excess of bromine by adding phenol solution and allow to stand for 10 minutes; add 1 g. of potassium iodide, and after 15 minutes titrate the liberated iodine with N/10 sodium thiosulphate, using starch as indicator towards the end of the titration. Each ml. of N/10 thiosulphate is equivalent to 0.001603 g. of polysulphide sulphur.

Lime-Sulphur Solution. The specification of the Association of British Insecticide Manufacturers (Bulletin No. 82; Ministry of Agriculture and Fisheries) for lime-sulphur solution requires it to be clear and free from sludge and of sp. gr. about 1.3, with not less than 18.5% *w/w* of polysulphide sulphur equivalent to about 24% *w/v*.

Potassa Sulphurata (B.P.). Contains 42 to 45% of total sulphur assayed by precipitation as sulphate from a solution in sodium hydroxide solution oxidised with bromine solution. Potassa Sulphurata, *U.S.P. XII*, contains not less than 12.8% of S in combination as sulphide; assayed by addition of a copper sulphate solution to a solution of the substance, filtering and adding hydrogen sulphide solution to the filtrate, acidified with acetic acid; no black precipitate should be produced.

Kalium sulfuraturn crudum, *P. Helv. V*, should contain not less than 18% of sulphur polysulphides by the given process. Dissolve 2 g. in water and adjust to 50 ml. Also mix separately 60 ml. of water, 1 g. of boric acid and a few fragments of pumice, boil and add first 0.15 g. of potassium cyanide and at once 5 ml. of the sulphurated potash solution and boil for 10 minutes. Cool and adjust to 100 ml. Acidify 50 ml. with 1 to 2 ml. of hydrochloric acid, add bromine water till just coloured, removing the excess with phenol solution. After 10 minutes add 1 g. of potassium iodide, stand for 15 minutes and titrate with N/10 sodium thiosulphate. 1 ml. of N/10 $\text{Na}_2\text{S}_2\text{O}_3 = 0.001603$ g. of polysulphides.

Mesulphenum (B.P.C. Supp. III). $\text{C}_{14}\text{H}_{18}\text{S}_2 = 244.2$. Contains 23.0 to 26.2% of S, determined by digestion with fuming

nitric acid in a sealed tube at 300° for six hours and weighing as barium sulphate. Sp. gr., 1.20 to 1.22. A test for chloride and inorganic sulphide is included.

THYMOL

Thymol (B.P.). $C_{10}H_{14}O=150.1$. M.p., 48° to 51°. Residue on evaporation from an open dish on a water-bath, not more than 0.05%. The solution in alcohol is neutral to litmus and optically inactive. Oily drops do not separate on standing from a 20% w/v solution in 10% w/v sodium hydroxide solution, which is clear and colourless or pale red. The *Fr. Cx.* 1937 determines the purity of thymol by precipitation as thymol iodide in alkaline solution. Thymolum, *P. Helv. V*, by treatment with N/10 bromide-bromate solution, hydrochloric acid and carbon tetrachloride during 30 minutes, addition of potassium iodide and titration with N/10 sodium thiosulphate, contains 99% of $C_{10}H_{14}O$.

An official method for the determination of thymol is described in *Methods of Analysis (A.O.A.C., 1940, 600)*. A solution of thymol in dilute alkali is warmed with hydrochloric acid and standard bromine solution, methyl orange indicator is added and the titration with bromine solution completed. Details are also given for the determination of thymol in antiseptics.

Thymolis Iodidum (B.P.C.). $C_{20}H_{24}O_2I_2=550.0$. By the B.P. method described under Iodophthaleinum, the substance dried over sulphuric acid contains not less than 40% of I. Loss over sulphuric acid, not more than 5%. Sulphated ash, not more than 3%. Thymolis Iodidum, *U.S.P. XII*, contains, after drying over sulphuric acid, not less than 43% of iodine. Assayed by igniting with potassium carbonate, oxidising the solution with potassium permanganate, decolorising with alcohol, filtering, adding potassium iodide to a portion, acidifying and titrating with sodium thiosulphate. Dithymol-di-iodé, *Fr. Cx.* 1937, assayed by the given process, contains not less than 99% of the pure substance. Dissolve, with gentle heat, 40 ml. of sulphuric acid, 1.5 g. of silver nitrate and 5 g. of potassium dichromate; after cooling again, add 0.25 g. of the thymol iodide and warm (not above 150°); after cooling, add 150 ml. of water and pass in sulphur dioxide, filter off the silver iodide, dry and weigh.

Oleum Thymi (B.P.C.). By the B.P. method for eugenol in Oleum Caryophylli, it contains not less than 40% w/v of phenols. Sp. gr., 0.905 to 0.960; $n_{D_{20}^{\circ}}$, 1.483 to 1.510. Soluble in 2 volumes of alcohol (80%). Oleum Thymi, *N.F. VII*, contains not less than 20% v/v of phenols. Sp. gr. at 25°, 0.894 to 0.930. Assayed by measurement of the volume of oil unabsorbed by potassium hydroxide solution. Oleum Thymi, *P. Helv. V*, contains 20 to 42% of phenols (thymol and carvacrol); assayed by interaction during 30 minutes of the portion soluble in sodium hydroxide solution, with N/10 bromide-bromate solution, carbon tetrachloride and hydrochloric acid; followed by titration of the iodine, liberated from

potassium iodide, with N/10 sodium thiosulphate. The *Fr. Cx.* 1937 requires Essence de Thym to contain not less than 25% of phenols, calculated as thymol, by an assay process similar to that of the *P. Helv. V* but without the addition of carbon tetrachloride.

Thyme. The Food and Drug Administration of the U.S. Dept. of Agriculture defined thyme as the dried leaves and flowering tops of *Thymus vulgaris* L., containing not more than 14% of total ash, nor more than 4% of ash insoluble in hydrochloric acid.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

Oleum Ajowan (B.P.C.). By the *B.P.* method for eugenol in Oleum Caryophylli, the unabsorbed oil measures not more than 6 ml., equivalent to not less than 40% *v/v* of thymol. Sp. gr., 0.910 to 0.930; α_D , 0° to +2°; n_{D20} , 1.485 to 1.510.

Sage. The Food and Drug Administration of the U.S. Dept. of Agriculture defined sage as the dried leaf of *Salvia officinalis* L., containing not more than 12% of stems (excluding petioles) and other foreign matter.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

THYROIDEUM

Thyroideum (B.P. Add. I). Contains 0.09 to 0.11% of iodine in combination as thyroxine. Assayed by precipitation during 18 to 24 hours of an N/1 sodium hydroxide extract with sufficient N/1 sulphuric acid to render the mixture slightly acid to congo red, followed by ignition with sodium carbonate of the precipitate previously dried with sodium carbonate at 110°; after extraction of the residue with water, neutralisation with sulphuric acid, oxidation with bromine, etc., as in the assay process for Thyroxinsodium, the liberated iodine is titrated with N/200 sodium thiosulphate. Thyroideum, *U.S.P. XII*, contains 0.17 to 0.23% of iodine in thyroid combination, and is free from iodine in inorganic or any other form of combination than that peculiar to thyroid gland. Thyroide, *Fr. Cx.* 1937, dried at 105°, contains not less than 0.2% of organic iodine. Moisten 1.1 g. in a nickel crucible with 1 ml. alcohol, add 5 ml. of 20% pure potash solution and after 3 to 4 hours, stirring occasionally, evaporate and ignite, at first gently and then more strongly till completely incinerated. After cooling, dissolve in water, and re-ignite. After dissolving in boiling water, filter and wash till 200 ml. are obtained. To the colourless solution add 10 ml. of 2% potassium permanganate, boil for 10 minutes, decolorise the excess with alcohol, cool, dilute to 220 ml. and filter. To 200 ml. of filtrate add 10 ml. of acetic acid and 1 g. ammonium chloride and boil for 10 minutes to destroy nitrites. To the cooled liquid, add 10 ml. of acetic acid and 1 g. potassium iodide and after 5 minutes titrate with N/100 sodium thiosulphate (recently prepared from N/10). Water-soluble ash, not more than 4%; insoluble ash, not more than 3.5%.

Glandulæ Thyreoidæ siccatae, *P.G. VI*, is standardised to contain not less than 0.18% of iodine. Thyreoides siccata, *P. Helv. V*, is prepared by drying the chopped glands below 50° and adjusting the defatted powder, if necessary, with lactose to contain

from 0.08 to 0.1% of thyroxine. The product should contain not more than 2% of fat, 8.5% of moisture, and yield not more than 5% of ash.

To avoid confusion, it should be borne in mind that thyroid *B.P.*, though standardised to 0.1% of iodine in combination as thyroxine, actually contains more than 0.2% of total iodine. Of the three iodines present in thyroid, only one, acid-insoluble thyroxine iodine, is recognised in the *B.P.* product, and it is on thyroxine iodine content solely that the *B.P.* standardisation is determined.—Armour & Co., *Brit. med. J.*, ii/1932, 780.

The use of a cold water extract of desiccated thyroid for the determination of the inorganic iodine as advocated in the *B.P.* '32 is inapplicable in the case of preparations which have been desiccated at low temperatures, since a considerable proportion of the thyroglobulin will not be denatured and will be extracted by the water.—H. G. Rees and A. H. Salway, *Quart. J. Pharm.*, 1932, 627.

A preparation obtained by low-temperature desiccation is most readily brought into line with the *B.P.* assay process by leaving in contact with alcohol for 17 hours and drying at 55° to 60°.—C. R. Harington and S. S. Randall, *ibid.*, 629.

Total iodine and acid-insoluble iodine determinations in thyroid gland are described. The standardisation of thyroid on a basis of acid-insoluble iodine content requires only one determination of iodine. It is unnecessary to fix a standard for total iodine content, and determinations of "inorganic" iodine no longer serve any useful purpose.—G. Middleton, *Analyst*, 1932, 603.

Inorganic iodides in dry thyroid may be determined by shaking 0.2 to 3 g. for 2½ hours in a stoppered tube with 20 ml. of cold methyl alcohol, filtering and washing with methyl alcohol; the extract is evaporated and the iodine in the residue determined.—W. Lawson, *Biochem. J.*, 1933, 112.

Recent experiments indicate that most of the iodine is bound to protein, but can be extracted from the protein by butyl alcohol. This extract, in turn, can be separated into "thyroxin-like" and "diiodotyrosine-like" fractions. Salter has suggested the following classifications of iodine fractions in the plasma: (1) "I" iodine, non-precipitable and presumably inorganic, and (2) "P" iodine, the maximum amount precipitated with the protein. The "P" fraction may then be separated into a "T" (thyroxin-like fraction) and a "D" (diiodotyrosine-like fraction).—T. Lerman, *J. Amer. med. Ass.*, ii/1941, 349.

The faults found with Hunter's method, as modified in the *U.S.P. X*, are loss of iodine on acidifying the solution of carbonates with phosphoric acid, and the introduction of oxychlorine compounds, including chloric acid, by the use of sodium hypochlorite solution. These compounds also liberate iodine from potassium iodide, and are not eliminated by boiling. With due care during neutralisation the first-mentioned source of error can be minimised, and where a fair proportion of iodine is present, error due to oxychlorine compounds is negligible. Where the iodine content is considerably less than 0.2%, a modification of Kendall's method is best. One gramme of the substance is gently heated with powdered caustic soda in a nickel crucible over an Argand burner. The crucible is heated more strongly until all the organic matter is oxidised, but no nitrate is added. The melt is extracted with water and filtered. Using bromophenol blue as indicator, the mixture is neutralised with phosphoric acid (sp. gr., 1.75). Excess bromine water is added, and an excess of 2 ml. of phosphoric acid. The liquid is boiled to half its volume to expel bromine, the remaining traces being eliminated by adding salicylic acid after cooling. The iodine is liberated from the iodate by the addition of potassium iodide solution and the iodine titrated with N/200 thiosulphate.—Wilfred Smith, *Quart. J. Pharm.*, 1928, 372.

The following method is stated to be preferable to fusion with alkali, as in *P. Ned. V*, and to alkaline oxidation methods. 200 mg. of sample is dissolved in 5 ml. of warm 4N sodium hydroxide and the solution shaken with 200 mg. of talc. 50 ml. of 4% potassium permanganate and 25 ml. of 4N sulphuric acid are added, and the solution heated in a 300 ml. Erlenmeyer flask, on which is a mark indicating 75 ml., until it begins to froth, after which it is boiled gently for 5 minutes. The mixture is cooled, about 3 g. of sodium bisulphite added to destroy the excess of permanganate, and the liquid boiled with 3 ml. of N/10 silver nitrate to remove SO_4 . The solution is boiled with 15 ml. of 50% nitric acid, filtered when cold, and the residue washed until free from acid. The precipitate

is washed back into the original flask, the liquid diluted to 75 ml., and 5 ml. of dilute sulphuric acid and 10 ml. of fresh bromine water added to convert silver iodide to the bromide and the iodine to iodate. The excess of bromine is boiled off and the liquid titrated with N/100 sodium thiosulphate. 1 ml. of N/100 thiosulphate solution is equivalent to 0.212 mg. of iodine.—J. C. de Jong, *Pharm. Weekbl.*, 1937, 1429.

The variation in the total iodine and thyroxine iodine contents of fresh gland and dried defatted glands is so great that there can be no satisfactory correlation between thyroid B.P. '32 and preparations expressed in terms of fresh gland or unstandardised dried defatted gland.

Biological Methods of Assay. There are three biological methods for estimating the activity of thyroid. An early method was that introduced by Reid Hunt, known as the acetonitrile test, which depends on the rise in resistance to acetonitrile produced in mice by the administration of thyroid. A dose of acetonitrile injected into each of a group of mice will kill a certain percentage. If the mice have previously received thyroid the same dose will kill a smaller percentage. Two samples of thyroid can thus be compared by observing what reduction in the percentage each causes. The relative potency of the two samples is, of course, not directly proportional to the respective reductions in percentage mortality, but can be determined from previous experiments in which the effect of different doses of the same sample of thyroid has been determined.

A second method of observing the physiological action of thyroid is to determine its effect on oxygen consumption, or on carbon dioxide production. The oxygen consumption of guinea-pigs, rabbits or rats can be estimated by placing the animal in a metal chamber immersed in water at constant temperature. The chamber contains a soda-lime tower to absorb carbon dioxide, and oxygen is admitted as required through a bubble trap. The passage of each bubble of oxygen is recorded on a smoked paper by a mechanical device, and the number of bubbles in a given period of time is a measure of the oxygen consumption. The volume of a bubble is previously determined when calibrating the instrument. The administration of thyroid raises the oxygen consumption, and different samples of thyroid can be compared by finding what doses produce the same rise in oxygen consumption.

A third method of estimating the potency of thyroid is by means of its effect in causing loss of body weight in guinea-pigs. Two groups of six guinea-pigs may be taken and their weights observed from day to day. One sample of thyroid is administered to one group, daily for six days, while a second sample, to be compared with the first, is administered to the second group. The mean loss of weight in each group can then be determined. The more potent sample produces the greater loss in weight; the relative potency of two samples is most rapidly found by finding a dose of one which produces an effect lying between the effects produced by two doses of the other.

Tabellæ Thyroidei (U.S.P. XII). Contain iodine equivalent to 0.17 to 0.23% of the labelled amount of thyroid, including all tolerances. Assayed by mixing a weighed quantity of powdered tablets with alcohol, sodium hydroxide solution and anhydrous sodium carbonate, drying and heating at 525° to 550° for 20 minutes, extracting the residue with water and filtering the extract. Bromine solution is added to the warm filtrate, the mixture allowed to stand 5 minutes, and then boiled to remove excess bromine. After cooling, phosphoric acid and potassium iodide solution are added and the liberated iodine titrated with N/10 sodium thiosulphate. A blank determination is carried out on the materials used.

Thyroxinsodium (B.P. Add. I). $C_{15}H_{10}O_4NI_4Na = 798.8$. Contains from 61 to 65% of I. The B.P. Add. I assays Thyroxinsodium by direct ignition with sodium carbonate, extraction of the residue with water, neutralisation with sulphuric acid (50% v/v) and oxidation by boiling for 10 minutes with 1 ml. of the sulphuric acid, 0.2 ml. bromine and adding a small piece of marble; after cooling, 0.2 ml. of phenol in glacial acetic acid (25% w/v) is added, followed by potassium iodide and titration with N/20 sodium thiosulphate, using starch mucilage as indicator; 1 ml. of N/20 sodium thiosulphate = 0.001058 g. of I. Thyroxinum,

U.S.P. XII, contains not less than 64% of iodine; it is assayed by igniting the substance, dried over sulphuric acid for 24 hours, with potassium carbonate, treating the water extractive with potassium permanganate, discharging the colour with alcohol, filtering, and titrating a portion of the filtrate, after adding potassium iodide and acid, with N/200 sodium thiosulphate.

Thyroxine (*Fr. Cx.* 1937). $C_{15}H_{11}NO_4I_4=776.8$. Assayed similarly to Thyroïde, *Fr. Cx.*, contains not less than 60% of iodine. Limit of diiodotyrosine, as matter insoluble in aqueous mixture adjusted with hydrochloric acid to pH 3.5, not more than 2%.

Parathyroid Extract.

Biological Method of Assay. The potency of parathyroid extract has been determined by injecting it subcutaneously into dogs to observe whether a rise in the amount of serum calcium occurs. This method suffers from the disadvantage that a given dose produces a different effect in different dogs, and the maximum rise occurs at a variable time. A more accurate method has been proposed by Dyer, who found that the injection of the extract into rats caused a rise in the amount of urinary calcium. Dyer (*Quart. J. Pharm.*, 1933, 426) uses ten rats which are placed in separate cages to allow collection of the urine. The output of calcium is determined, the urine of five rats being pooled, and the urine of the other five also being pooled. These observations are made for two or three days. The one group of rats is then injected with the extract which is used as standard, and the second group with the preparation which is being tested. The injections are given daily for two or three days. If the potency of the doses given is exactly equal, the rise in output of calcium in the two groups is the same.

If the potency of the doses is not exactly equal, the dose with the greater potency produces the greater rise in urinary calcium. But it is not possible to calculate the relative potency of doses which produce unequal rises in calcium output. When unequal rises occur, the experiment must be repeated until a dose of the unknown preparation is found which produces the same rise as a dose of the standard.

Injectio Parathyroidei (*U.S.P. XII*) replaces *Liquor Parathyroidei U.S.P. XI*. 1 ml. possesses a potency of not less than 100 *U.S.P.* parathyroid units; each unit representing 1/100 of the amount required to raise the calcium content of 100 ml. of normal dog blood serum by 1 mg. within 16 to 18 hours after administration.

TRAGACANTHA

Tragacantha (*B.P.*). Foreign organic matter, not more than 2%. The powder does not acquire a pink colour in ruthenium red solution. Ash limit, 4%. *Tragacantha, U.S.P. XII*, complies with a test for karaya gum.

The following tests for identity of tragacanth are recommended by the Subcommittee on Crude Drugs of the Committee on Pharmacy and Pharmacognosy:—To 4 ml. of a 0.5% *w/v* solution in water, add 0.5 ml. of hydrochloric acid and heat for thirty minutes in a water-bath. Divide the liquid into two parts. To one part add 1.5 ml. of solution of sodium hydroxide and 3 ml. of solution of potassium-cupric tartrate and warm in a water-bath; a red precipitate is produced. To the remainder of the liquid add solution of barium chloride; no precipitate is produced (distinction from agar). When powdered, it does not acquire a pink colour in solution of ruthenium red (distinction from sterculia gum and from agar). On the addition of N/10 iodine, it acquires an olive-green colour (distinction from acacia and from agar).—(*British Pharmacopæia Commission Report*, No. 13, September 1939.)

The following test provides a means of comparing specimens of tragacanth, but it is necessary that tests should be carried out at the same time and under exactly the same conditions if comparative results are to be obtained:—The tragacanth should be in the form of powder, or, if in flake form, should be

reduced to a powder which passes a No. 30 sieve and is retained by a No. 60 sieve. Prepare a mucilage of 1.25% strength as described in the *B.P.* for *Mucilago Tragacanthæ*; heat for 1 hour on a boiling water-bath, with occasional stirring, pour it into a 50 ml. Nessler cylinder and allow it to stand overnight. At the surface of this mucilage release a steel ball, $\frac{5}{32}$ in. in diameter, and take the time of fall from a point 1.5 in. to a point 4 in. below the upper surface; the time required is from 50 to 150 seconds for average specimens of tragacanth when freshly powdered. Occasional specimens give much higher results.

The comparison between samples of gum tragacanth should be made by comparison of the viscosities of 0.4% aqueous mucilages in poises at 20.0°. If a gum gives a mucilage with a viscosity above 1.3 poises it may be regarded as of good quality.—*L. A. Haddock, Quart. J. Pharm.*, 1934, 505.

Its most important character is its power to form a mucilage, yet no test, such as the falling ball method, is included in the *B.P.* for distinguishing different qualities.—*Pharm. J.*, ii/1932, 208.

The quantity of volatile (acetic) acidity developed in the acid hydrolysis of gum tragacanth affords a valuable index of the purity of this commodity when compared with results obtained from so-called "Indian gum." A tentative method for the determination of volatile acidity is described.—*Methods of Analysis (A.O.A.C. 1940, 601)*.

UREA

Urea (*B.P.C.*). Melts between 130° and 132°. Ash, not more than 0.1%. M.p. of the *U.S.P. XII* substance, 131° to 133°. Alcohol-insoluble matter, not more than 0.04%.

Urethanum (*B.P. Add. IV*). $\text{NH}_2\text{COOC}_2\text{H}_5 = 89.06$. M.p. of the substance dried over sulphuric acid, 48° to 50°. Ash, not more than 0.05%. *Æthylis Carbamas*, *U.S.P. XII*, melts between 48° and 50°. Loss on drying over sulphuric acid, not more than 2%; ash, not more than 0.1%. 1 g. in 5 ml. of alcohol forms a practically complete and colourless solution. Tests for nitrate and urea are included.

Carbromalum (*B.P.*). $\text{C}_7\text{H}_{13}\text{O}_2\text{N}_2\text{Br} = 237.0$. M.p., 116° to 118°. Complies with limit tests for carbonisable substances, chlorides and sulphates. Ash, not more than 0.05%.

Suraminum (*B.P. Add. IV*). $\text{C}_{51}\text{H}_{34}\text{O}_{23}\text{N}_6\text{S}_6\text{Na}_6 = 1428.6$. pH of a 1% solution in recently boiled and cooled water, 6.2 to 6.8, using bromothymol blue indicator. Contains in 5 g. free amine equivalent to not more than 0.4 ml. of N/10 sodium nitrite. Complies with tests for absence of undue toxicity, as indicated by intravenous injection of mice, and for therapeutic potency as indicated by intravenous injection of mice infected with a strain of *Trypanosoma equiperdum*.

VALERIANA

Valeriana (*B.P. Add. IV*). Foreign organic matter, not more than 5%. Ash, not more than 12%. The *B.P. Add. IV* allows the use of Indian valerian when valerian is prescribed or demanded. The *N.F. VII* requires a foreign matter limit of 4% and an acid-insoluble ash limit of 8%.

A water-soluble base possessing physiological activity is present in appreciable quantity in dried valerian root. The base is soluble in cold and hot water, and in alcohol, sparingly soluble in ethyl acetate, and insoluble in acetone, chloroform and ether. It is precipitated from a solution in amyl alcohol by ether. When distilled in high vacuum it decomposes at 200° . It has not yet been crystallised. The vapours evolved on heating the base with zinc dust did not give the characteristic red colour on pine wood of a pyrrole derivative. Physiologically it caused a fall in blood pressure in an urethane-anesthetised cat followed by a secondary effect on the heart; it also had an inhibiting effect on peristalsis. These effects require confirmation when the basis obtained is pure. Details are given for the separation of the base.—*Pharm. J.*, i/1939, 299.

Valeriana Indica (B.P. Add. IV). Contains not more than 2% of other foreign organic matter. Ash, not more than 12%.

Ammonii Valeras Acidus (N.F. VII). By distillation of the ammonia liberated with sodium hydroxide it yields the equivalent of from 33 to 38% of ammonium valerate, $C_4H_9 \cdot COONH_4$; and by titration with standard alkali to phenolphthalein, the acidity corresponds to 62 to 67% of free valeric acid, $C_4H_9 \cdot COOH$.

Ferri Valerianas (B.P.C.). Residue on ignition, not less than 24%.

Sodii Valerianas (B.P.C. Supp. IV). $C_5H_9O_2Na = 124.1$. Contains not less than 85% of the pure substance. Assayed by titration of a solution with N/2 sulphuric acid to bromophenol blue removing most of the acid produced with ether.

Zinci Valerianas (B.P.C.). $C_{10}H_{18}O_4Zn, 2H_2O = 303.6$. On treatment with nitric acid and gentle ignition, yields 25 to 28% of ZnO .

ZINCUM

Zinci Carbonas (B.P.C.). Residue on ignition, not less than 68%.

Determination of Zinc. A slightly acid solution containing zinc, free from metals other than the alkalis or alkaline earths, and from ammonium acetate, is made slightly alkaline with sodium hydroxide, then acidified with acetic acid and diluted so that above 0.1 g. of zinc is present in each 150 to 200 ml. Excess of sodium anthranilate solution is then added slowly with shaking, which is continued for 3 to 5 minutes. After standing for 20 minutes the zinc anthranilate is filtered off, washed with sodium anthranilate solution, then with alcohol and dried at 105° to 110° . 1 g. of precipitate corresponds to 0.2411 g. of zinc oxide or 0.1937 g. of Zn. The reagent is prepared by dissolving 3 g. of anthranilic acid in dilute sodium hydroxide solution in amount just insufficient to neutralise and diluting to 100 ml. The zinc solution is best prepared by precipitating the zinc as sulphide, igniting the precipitate to oxide and dissolving the latter in the minimum quantity of hydrochloric acid.—E. A. Ostroumow, per *Analyst*, 1937, 690.

Zinc can be determined by means of 8-hydroxyquinoline, (*syn.* Oxine), $C_8H_7N \cdot OH$. To the test solution, which should be slightly acid and should contain about 0.05 g. of Zn in 50 ml., is added 3 g. to 5 g. of sodium acetate. After warming to 60° to 70° , the zinc is precipitated by the addition of excess of the alcoholic 8-hydroxyquinoline solution. The precipitate is collected, washed and dried. If dried at 100° , the composition is $Zn(C_8H_6ON)_2, 1\frac{1}{2}H_2O$ and the Zn content is 17.18%; at 120° to 130° the crystals become anhydrous, and then contain 18.50% of Zn. The precipitate may also be determined volumetrically as described for magnesium. Each millilitre of N/5 bromine is equivalent to 0.001635 g. of Zn.

The oxine complex can be weighed as the dihydrate after drying at 98°. After drying at 160° the weight of the precipitate corresponds to the crystalline anhydrous form. The slightly high results at 110° are therefore associated with residual dihydrate, and at 140° presumably with the retention of water by the anhydrous form in the amorphous condition. The practical point emerging is that instructions need to be more precise than, say, "dry at 100°"; the hydrated form may possibly be retained by drying in a steam oven, but the more certain procedure is to dry the anhydrous form at 160°.—R. C. Chirnside, C. F. Pritchard and H. P. Rooksby, *Analyst*, 1941, 399.

Zinc in Food. Determination of zinc in foods using diphenylthiocarbazone. Results are given for a variety of food materials.—N. D. Sylvester and E. B. Hughes, *Analyst*, 1936, 734.

Zinci Oxidum (B.P.). $\text{ZnO} = 81.38$. Loses not more than 1% on ignition, and then contains not less than 99% of ZnO . Assayed by dissolving the substance and ammonium chloride in excess N/1 sulphuric acid and back titrating with N/1 sodium hydroxide to methyl orange. The *U.S.P. XII* omits the ammonium chloride in the titration to methyl red indicator, and requires a purity of 99% in the freshly ignited substance.

Emplastrum Zinci Oxidi (B.P.C.). Weight per sq. yd. not less than 8 oz., and of the base cloth $3\frac{1}{2}$ oz., and the difference between these weights not less than $3\frac{1}{2}$ oz. The cotton cloth complies with the standard for the cotton cloth of *Emplastrum Adhesivum*. Tensile strength of the warp, not less than 45 lbs. per inch width.

Unguentum Zinci Oxidi (U.S.P. XII) is assayed by ignition and weighing the greyish-white residue of oxides. 18.5 to 21.5% of ZnO should be indicated.

Calamina (B.P.C. Supp. IV). Residue on ignition, 68 to 90%. Matter insoluble in hydrochloric acid, not more than 1%. The filtrate from 2 g. shaken with 20 ml. of water and 5 ml. of glacial acetic acid remains clear on addition of 5 drops of potassium chromate solution (limit of lead) and the filtrate from 0.5 g. shaken with 5 ml. of water and 1.5 ml. glacial acetic acid, made ammoniacal and precipitated with hydrogen sulphide, on acidification with acetic acid and addition of ammonium oxalate solution produces no turbidity (limit of calcium and barium salts). *Calamina Præparata, N.F. VII*, loses on ignition not more than 1% and then, by titration of the filtrate from solution in excess standard sulphuric acid with standard sodium hydroxide to methyl orange, contains not less than 98% of ZnO .

The following tests for purity are recommended by the Sub-Committee on Inorganic Chemicals of the Committee on General Chemistry:—Dissolve 1 g. in 20 ml. of warm dilute hydrochloric acid, filter, and wash with water; the residue after being dried at 100° weighs not more than 0.01 g. (limit of matter insoluble in hydrochloric acid). Shake 1 g. with 10 ml. of water and filter; the filtrate is colourless (absence of water-soluble dyes). Shake 1 g. with 10 ml. of alcohol (90%) and filter; the filtrate is colourless (absence of alcohol-soluble dyes). Dissolve 2 g. in a mixture of 20 ml. of water and 5 ml. of glacial acetic acid, filter, and add 5 drops of solution of potassium chromate; the solution remains clear (limit of lead). Dissolve 1 g. in a mixture of 10 ml. of water and 2.5 ml. of glacial acetic acid, filter, make alkaline by the addition of solution of ammonia, and add 2 ml. of solution of ammonium oxalate; no turbidity is produced (limit of calcium and soluble barium salts). 0.5 g. dissolved in water by the addition of 3 ml. of nitric acid, complies with the limit tests for chlorides. 0.2 g. dissolved in water by the addition of 2 ml. of hydrochloric acid, complies

with the limit test for sulphates. Leaves, on ignition, not less than 68%, and not more than 72%, of residue.—(*British Pharmacopœia Commission Report*, No. 14, September 1939.)

Nebcalamina Præparata (N.F. VII). Contains, after ignition, not less than 92% ZnO. In the assay, iron is removed by precipitation with excess ammonium hydroxide, and the filtrate, after addition of slight excess HCl, is titrated against N/10 potassium ferrocyanide, using ferrous ammonium sulphate as indicator.

Zinci Oleostearas (B.P.C.). By the B.P. method for Zinci Stearas, it contains 12 to 14% of zinc, calculated as ZnO.

Zinc (Peroxyde de) (Fr. C.x. 1937) by titration with potassium permanganate contains not less than 35% ZnO₂.

Zinci Stearas (B.P.). Contains zinc equivalent to from 13 to 15.5% of ZnO. Assayed by boiling in excess of N/10 sulphuric acid for 10 minutes, filtering and titrating the filtrate and washings with N/10 sodium hydroxide to methyl orange. The U.S.P. XII substance, assayed similarly, is of the same strength.

Titanic Chloride, TiCl₄, is kept in sealed tubes. It reacts violently with water and forms a white precipitate. On adding ammonia complete precipitation of the hydroxide occurs.

Titanous Chloride, TiCl₃, is supplied in 15% solution which is used as a reducing agent and employed in volumetric analysis for the determination of iron and of organic nitro-compounds. N/10 solution is prepared by diluting approximately 1 volume with 1 volume of concentrated hydrochloric acid and 8 volumes of water and standardising immediately before use with N/10 ferric ammonium sulphate. It should be freshly prepared, or preserved in an atmosphere of hydrogen or carbon dioxide.

Titanic Oxide, TiO₂. A white powder, extremely insoluble in ordinary solvents. It does not dissolve in boiling nitric acid or aqua regia. Used as an ingredient of toilet powders and as a white pigment in place of "White Lead." RUTILE is the ore titanium dioxide used in leather dyeing.

Titanous Sulphate, Ti₂(SO₄)₃, usually supplied in 15% solution, is employed as a reducing agent.

Detection of Tin. Small amounts of tin may be detected by means of diazine green (*syn.* Janus green). The reagent is used as a 0.01% aqueous solution and the test is especially useful for the detection of tin in the presence of antimony in the sulphides obtained in systematic qualitative analysis. The sulphides are dissolved in strong hydrochloric acid and reduced with metallic iron. One drop of the solution is added to 1 ml. of the reagent. In the presence of tin there is a colour change from the blue to violet or red.

Tin may be detected by using α -dinitrophenylaminesulphoxide, NH(C₆H₄.NO₂)₂SO. The reagent is used as a 0.2% solution in N/10 sodium hydroxide. The tin is precipitated from the test solution by means of hydrogen sulphide and the liquid filtered. The precipitate and filter are boiled with concentrated hydrochloric acid, the solution filtered and to the filtrate is added a piece of zinc foil. While the zinc is dissolving, a stream of carbon dioxide is passed through the liquid. When the metal has dissolved, 2 ml. of reagent is added and the mixture heated for 2 minutes, carbon dioxide still being passed through it. The liquid is diluted with water, 1 to 2 drops of ferric chloride solution added and the liquid filtered. If tin is present, the filtrate is coloured violet. For the detection of tin in, for example, canned foods the organic matter must first be destroyed by boiling with sulphuric acid and potassium bisulphate.

Determination of Tin in Foods. A distillation method for quantitative separation and estimation of tin in foodstuffs is described:—Incinerate 5 to 20 g. material, according to the amount of tin suspected, in a silica dish. Transfer the charred mass to a distillation flask and transfer any residue in the dish by digestion with sulphuric acid A.R. Make up volume in flask to 30 ml. with sulphuric acid A.R. Connect the flask to a water-cooled condenser attached to three small wash bottles, each containing 5 ml. of water. Heat the distillation flask in an oil bath to 220° and drop hydrobromic acid (sp. gr., 1.46–1.49) on to the contents of the distillation flask, at the rate of 1–2 drops per second. Meanwhile, maintain a steady current of dry CO₂ through the absorption flasks. Continue the distillation for 30 to 45 minutes. Rinse the condenser and dilute the distillates to 50 to 100 ml., according to amount of tin suspected.

Colorimetric Determination.—Take an aliquot portion of distillate containing 20–25 μ g. of tin and add just sufficient phenol (25% in glacial acetic acid) to render it free from bromine. Determine the acidity by titration with N sodium hydroxide using methyl orange indicator. For the test, take a further aliquot portion, and add phenol reagent and the calculated amount of 30% sodium hydroxide solution. Add 4 drops of thioglycollic acid (0.04% aqueous solution) to reduce stannic tin, 3 to 4 drops of a fairly stiff agar agar mucilage and 1 ml. of 0.1% solution of toluene-3:4-dithiol in 1% *w/v* solution of sodium hydroxide. Make up the total volume to 10 ml. Heat the solution in boiling water for 1 minute and compare the resulting colour with those given by standard tin solutions, similarly treated.—H. N. Law, *Analyst*, 1942, 283.

Detection of Molybdenum and Tungsten. To 10 ml. of the solution to be examined, containing between 1 and 0.02 mg. of molybdenum or tungsten, add sodium hydroxide or hydrochloric acid until the mixture is neutral to litmus, and then 10 drops of hydrochloric acid and 3 drops of thioglycollic acid. Molybdenum gives a bright yellow solution, tungsten a colourless solution. Mix this solution with 1 ml. of dimercaptobenzene (dithiol) reagent, and boil for 3 to 4 minutes. Molybdenum gives a dark green precipitate and tungsten a light greenish-blue precipitate. Finally, cool the mixture and add an excess of ammonia (0.880). A bright blue colour indicates molybdenum, a colourless solution tungsten. Iron interferes with the test and if present should first be precipitated by sodium hydroxide and filtered off.—J. H. Hamence, *Analyst*, 1940, 152.

ZINGIBER

Zingiber (B.P.). Alcohol (90%)-soluble extractive, not less than 4.5%. Water-soluble extractive, not less than 10%. Ash limit, 6%. Water-soluble ash, not less than 1.7%. Zingiber, *U.S.P. XII*, yields not less than 4.5% of ether-soluble extractive and not less than 12% of cold-water extractive.

The Food and Drug Administration of the U.S. Dept. of Agriculture defined ginger as the washed and dried, or decorticated and dried, rhizome of *Zingiber officinale* Roscoe. Required to contain not less than 42% of starch, not more than 8% of crude fibre, not more than 1% of lime, not less than 12% of cold-water extract, not more than 7% of total ash, not more than 2% of ash insoluble in hydrochloric acid, nor less than 2% of ash insoluble in cold water. *Jamaica Ginger*: Ginger grown in Jamaica, containing not less than 15% of cold-water extract and otherwise as ginger. *Limed Ginger*, bleached ginger: whole ginger coated with calcium carbonate, containing not more than 4% of calcium carbonate nor more than 10% of total ash, and otherwise as ginger.—*S.R.A., F.D., No. 2, Rev. 5, Nov. 1936.*

Proportion of Extractive. The darker outer layers of ginger yield much higher proportions of extractive to alcohol and to ether than are yielded by the inner portions. Four samples of (scraped) Jamaica ginger gave the following ranges of percentage yields for the outer and inner portions respectively:—Alcohol, 4.4–5.0, and 2.4–2.8; ether, 5.5–6.7 and 3.0–3.5. With African ginger (5 samples) the figures were:—Alcohol, 6.5–9.1 and 3.4–4.0; ether, 9.2–13.0, and 4.2–4.9. With Cochin ginger (5 samples) the figures were:—Alcohol, 6.0–8.2 and 2.5–3.2; ether, 8.4–11.2 and 2.8–4.0. Only 3 out of 13 samples of exhausted ginger showed gelatinised starch granules and since low values for the extractive may be due to the removal of the outer layers, it is not possible to detect the presence of small admixtures of exhausted ginger with certainty. It may be assumed that a sample with an alcoholic extract of less than 3.0% is adulterated. One with an alcoholic extract of 3.0–4.5% may be genuine but the fibre should be less than about 3.0% and the aqueous extract not less than about 12%.—G. D. Elsdon and C. Mayne, *Analyst*, 1937, 836.

PROPRIETARY MEDICINES

An early attempt to control the advertising and sale of proprietary medicines for which extravagant therapeutic claims were made was the publication by the British Medical Association of *Secret Remedies: What they cost and what they contain* (1909), followed by *More Secret Remedies* (1912). In 1912 the House of Commons appointed a Select Committee to inquire into the conditions prevailing in the United Kingdom regarding the sale and advertising of proprietary medicines, medical preparations and appliances. The Report of the Committee was issued in 1914 and was reprinted as a supplement to the *Lancet*, January 10, 1925 ("Sale of Patent Medicines.") It was found that this country differed from the Dominions and most foreign countries in having no Government Department or official charged with the duty of controlling the advertising and sale of proprietary remedies, and that the existing law offered no check to gross abuse of the public. It was recommended that the administration of the law governing the advertising and sale of patent, secret and proprietary medicines be part of the functions of the Ministry of Health. The Committee considered that the exhibition of formulæ was not a "proper, practical or effective measure." The reasons given for taking this view were, firstly, that such a procedure would inflict grave hardship, sometimes amounting to ruin, upon proprietors of secret remedies and losses of their investments upon shareholders. Secondly, that the disclosure of composition would be meaningless to most purchasers. Thirdly, that it was the duty of the State to protect subjects against injury and fraud. Experience during recent years of the practice of "de-stamping" (*vide infra*) has shown that the fear that disclosure of formulæ might involve the proprietors of secret remedies in ruin was completely groundless. The Committee further suggested that pure drugs, vended entire under fancy names, should no longer be exempt from duty, that the distinction between the name of an ailment and the name of an organ, the seat of that ailment, should be abandoned, and that the exemption should not apply to medicines generating carbonic acid gas. It was also recommended that reference to the patent medicine stamp in advertising matter should be prohibited and that no name of a proprietor or firm should be printed on the stamp. The report also dealt with the law relating to proprietary medicines in the British Dominions, Germany, Austria, Hungary, France and Italy.

Proprietary Medicine Bills

In July, 1920, a Bill based on the recommendations of the Select Committee was introduced into the House of Lords. Among the proposals were the prohibition of the sale or advertising of remedies purporting to treat or cure certain diseases and the registration of proprietary medicines and their owners. The

proprietary medicine register was to be in two parts, one of which was to be used exclusively for recording the composition of the medicines. Authority was to be given to the Minister to require the disclosure on the label of any poisonous or dangerous ingredient, but apart from this no disclosure was to be required. Powers were to be given to remove a medicine from the register if it was considered injurious to health.

A Proprietary Medicine was defined as any medicine held out by advertisement, label, or otherwise in writing, as efficacious for the prevention, cure or relief of any malady, ailment, infirmity or disorder affecting human beings and

- (a) which is sold under a trade name or trade mark to the use of which any person has or claims or purports to have an exclusive right; or
- (b) of which any person has or claims or purports to have the exclusive right of manufacture or for the making of which any person has or claims or purports to have any secret.

For an analysis of the provisions of the Bill as amended in the Committee of the House of Lords, see *Chem. & Drugg.*, ii/1920, 1472; see also *ibid.*, ii/1920, 1503 and i/1921, 49.

After reaching the Report stage in the House of Lords the Bill was not proceeded with on account of the dissolution of Parliament. A further Bill, with essentially the same provisions, was drawn up by the Health Advisory Committee of the Labour Party and introduced in the House of Commons in May 1931, but was afterwards withdrawn.

Throughout the discussions on the Bill exception was taken to the disclosure of formulæ of proprietary medicines, but the position in this respect was altered completely by "de-stamping" (see below).

At the request of the Standing Committee on Scientific Research of the Economic Advisory Council, the Council of the Royal College of Surgeons gave their views on patent medicine legislation, the following being abstracted from a statement appearing in the 1934 Annual Report of the College.

"In the opinion of the Council the problem can only be adequately dealt with on the lines of the Select Committee of 1914 by bringing the sale of proprietary medicines and appliances under the control of the Ministry of Health. Such control should ensure: (1) that the article is not injurious; (2) that the description of its therapeutic action is not fraudulent; (3) that the sale of the article and the method of its advertisement are not against the public interest; (4) that no medicine or appliance is advertised as a cure for any of the following diseases and conditions:— blindness, Bright's disease, cancer, consumption, diabetes, epilepsy, fits, locomotor ataxy, lupus, paralysis."—per *Brit. med. J.*, ii/1934, 822.

In Canada a proprietary or patent medicine is defined by the Proprietary or Patent Medicines Act as "any artificial remedy or prescription manufactured for the internal or external use of man, the main composition or definition of which is not to be found in

the *British Pharmacopæia* . . . or other recognised and approved pharmacopœias or formularies . . . or upon which is not printed in a conspicuous manner the true formula or list of medicinal ingredients contained in it."—*Pharm. J.*, ii/1934, 590.

Medicine and Surgical Appliances (Advertisement) Bill

In 1936 a Bill with the above title was introduced into the House of Commons as a private member's Bill. The following were the principal provisions of this measure:—

- (1) Prohibition of holding out a medicine or appliance, whether directly or by implication (a) as a cure of Bright's disease, cancer, consumption, diabetes, epilepsy, fits, locomotor ataxy, lupus, or paralysis; (b) as a cure of amenorrhœa, hernia, blindness, or any structural or organic ailment of the auditory system; (c) for procuring miscarriage; (d) for the cure of habits associated with sexual excess, or for the promotion of sexual virility in men or of sexual desire in women.
- (2) Prohibition of publication of invitations to diagnosis by correspondence or to treatment of the above ailments by correspondence.
- (3) Provision was made to permit of advertisements of medicines for the above ailments being sent to medical practitioners and others.

When the Bill came up for second reading in March 1936, opponents suggested that it would unduly restrict the activities of the unorthodox practitioner, and that it was designed to safeguard the business of qualified doctors and chemists far more than to safeguard the public. Eventually, it was found that a quorum could not be obtained, and the House was "counted out." The British Advertising Association, which includes the proprietors of many of the most extensively advertised remedies has, however, adopted the criteria contained in this Bill and all advertisements of members of the Association must now conform to them.

Proprietary Medicines and Revenue

The immense increase in the sale of patent medicines since the Select Committee of 1912 was appointed is indicated by the fact that in 1928-9 the *revenue alone* from Medicine Stamp Duty reached a maximum of £1,333,512, whereas Dr. Cox, before the Select Committee (1912), made the statement (*Chem. & Drugg.*, i/1912, 923) that £2,500,000 had been *spent by the public* on patent medicines since 1908. The Report (1937) of the Select Committee on Medicine Stamp Duties suggested that, at a conservative estimate, the annual (retail) turnover in proprietary medicines was not less than £20,000,000. The number of patent medicine licence holders had increased from 29,000 in 1903 to 190,000 in 1934. Since 1929 the yield from the duty had rapidly decreased owing to the practice of de-stamping, and amounted only to £747,930 in 1935-6.

"De-stamping"

The Schedule to the Medicine Stamp Act, 1812, exempted from duty, when sold by chemists or doctors, any preparation containing ingredients of which the "different denominations, properties, qualities, virtues and efficacies . . . are known, admitted, and approved of in the preservation, cure, or relief of any disorder . . . in anywise affecting the human body," provided that no claims were made by manufacturer or vendor to the possession of a special right to prepare the medicine or of special skill in compounding the ingredients. A further condition of this exemption was that the medicine must not be and must never have been held out by the owner, compounder or first vendor as a cure for a disease. Once a medicine was liable to duty it was always liable, but this rule was easily evaded by making some slight alteration in the formula.

In order to take advantage of these exemptions, the majority of proprietary medicine manufacturers supplied, for sale by chemists, unstamped articles the formulæ of which were printed on the label; such preparations were vended as, say, "—Brand Cough Mixture." The brand name was registered as a trade-mark, which conferred proprietary rights on the *name*, although the label bore some statement such as "Proprietary rights are not claimed in the formula or method of preparation of this article except in the registered trade-mark." The majority of extensively advertised proprietary medicines were sold unstamped under brand names, the formulæ being disclosed.

Prior to 1930 the Commissioners of Customs and Excise had always regarded the exemption of known, admitted and approved remedies as applying to preparations of which the formula was published in a recognised work of reference (such as the *B.P.*, *B.P.C.*, or the *Extra Pharmacopœia*), provided the label bore an indication of the source of the formula. In 1930, they issued a notice requiring a "definite and complete statement of the actual ingredients (i.e., the full formula with proportions), and a statement that no proprietary rights are claimed in the medicine" to be printed on labels, cartons, etc. In 1932 an attempt to enforce this ruling in the Courts was unsuccessful (*Attorney-General v. Lewis and Burrows*), and exemption could be successfully claimed if the label indicated where the formula might be found in a well-known book of reference and proprietary rights were disclaimed.

Select Committee on Medicine Stamp Duties

The decline in revenue due to de-stamping led in 1936 to the appointment of a Select Committee "to consider the duties of excise chargeable under the Medicine Stamp Acts, and to make recommendations for the alteration of those duties, if thought fit, with a view to reforming the law relating thereto." The Committee, which reported in 1937, found that the existing law was quite inappropriate to modern requirements and that wholesale evasion of duty was practised. They considered that the trade in

medicinal articles was suitable for taxation, that the same product should not be sold by different vendors stamped and unstamped, and that a far larger range of preparations should be made liable to duty. The Committee proposed that duty should be chargeable on practically every type of preparation, whether a medicine, toilet requisite, cosmetic, article of confectionery, or medicated wine, which was recommended, held out or advertised in any way whatsoever for the prevention, cure or relief of any human ailment, etc., or for the protection or maintenance of bodily health. They proposed that exemption be granted to medicines recommended and sold to doctors and dentists, to medicines supplied to doctors and dentists for professional use and to all preparations supplied to doctors, dentists or pharmacists for dispensing purposes. They further urged that consideration should be given to the propriety of taxing foods and certain appliances (such as deaf aids), beverages and other preparations advertised as possessing properties beneficial for health. It was suggested that if difficulty was experienced in distinguishing between cosmetics which claim to be remedial and those which do not, consideration should be given to the taxation of all cosmetics. The rate of duty proposed was $\frac{1}{2}$ d. for articles retailing at $\frac{3}{4}$ d., exclusive of duty, rising to 1d. for those retailing from 3d. to 6d., and 1d. for every 6d. thereafter.

The sweeping character of these proposals evoked vigorous opposition from the interests affected. Among the objections raised to the suggestions were the necessity of stamping medicines dispensed in accordance with doctors' prescriptions and the fact that simple remedies such as Epsom salts would be dutiable if, at the time of sale, any recommendation was made as to their therapeutic effect.

Pharmacy and Medicines Act, 1941.

In April 1939 the Chancellor of the Exchequer, in opening the Budget, announced that the troublesome question of the Medicine Stamp Duties was to be settled finally by their abolition as from September 2nd, 1939, a date chosen to enable the existing licences to expire as they normally did on September 1st and also to give time to allow sufficient opportunity for the disposal of existing stocks. The cost to the Exchequer was estimated as £770,000 in a full year. Considerable opposition was aroused on a number of grounds. The proposal destroyed the long established pharmacists' privilege in respect of "known, admitted, and approved remedies" as no alternative was proposed and, if the duty was removed without some form of control, there would be no inducement to disclose the composition of any preparation. About two hundred Members of Parliament signified their intention to support an amendment to the Finance Bill with the object of postponing the repeal of the duties for five years. In the subsequent debate the Chancellor yielded to the wishes of the House and agreed to the postponement of the repeal for twelve months. At the same time he invited the House to assist him in

devising a workable measure to replace the obsolete enactments. The parliamentary discussion is reported in the *Pharmaceutical Journal* for July 1st, 1939. The Chancellor of the Exchequer, in the following August, announced that he and the Minister of Health jointly would appoint a Committee to consider the control and taxation side of the question. For the year ending March 31st, 1939, the total net receipts were £725,640, a figure £7000 lower than 1938 and the lowest since 1934-5. The number of licences issued had increased by about 3500 to a total of 167,371. It was, however, not until the introduction of the Budget in April 1941 that the Chancellor of the Exchequer was able to announce that he proposed to repeal the medicine stamp duties as from September 2nd, 1941. Sir Kingsley Wood said:

"The Committee will also remember that when the Finance Bill of July was being debated the question was raised of the application of the Purchase Tax to medicines subject to medicine stamp duty. It was pointed out that this involved a tax upon a tax, and comments were made upon the medicine stamp duties themselves which, as my predecessor told the House in 1939, had become administratively unworkable, and which it was highly desirable to repeal on that ground. I undertook before the introduction of the next Finance Bill to see whether the parties could be got together to hammer out some reasonable solution of the position.

"I am glad to be able to inform the Committee that the various interests concerned with the duties, assisted by my hon. and gallant Friend the Member for the Lonsdale Division of Lancashire (Sir Ian Fraser), have come together and have reached an agreement. I have consulted my right hon. Friend the Minister of Health on the matter, and as a result I am in a position to announce that the medicine stamp duties will be repealed and that my right hon. Friend, in accordance with the understanding which has been reached, will as soon as possible introduce legislation, the object of which will be to maintain a fair balance between the interests of the pharmacists and of other vendors. The repeal will come into operation from September 2nd so as to allow reasonable time for disposal of stamped stocks. We shall part therefore with the Act of 1802 and other Acts on this matter which in process of time have become a museum piece of administrative complexity. The cost of this repeal will be £640,000 this year and £840,000 in a full year."

Earlier in the year the Proprietary Association of Great Britain had presented a Memorandum dealing with the problem to the Chancellor which indicated the basis of an agreement between the interested parties in the following terms:—

The Pharmaceutical Society of Great Britain, the National Pharmaceutical Union, the Scottish Pharmaceutical Federation, the Company Chemists' Association and the Wholesale Drug Trade Association will raise no objection to the repeal of the Medicine Stamp Acts if at the same time there is inserted in the Finance Act repealing these duties a provision which gives the pharmacist equivalent privileges in exchange for that which he now enjoys, and this has been embodied in a draft Bill which is Annexure No. 2 hereto. The Proprietary Association of Great Britain and some of the other parties concerned in these negotiations have agreed that the acceptance of Annexure No. 2 shall be coupled with an undertaking by the Proprietary Association of Great Britain to support a Bill to control the industry, which Bill has been prepared and agreed in principle. The Proprietary Association of Great Britain undertakes to support this Bill accordingly, and it is hoped that the appropriate Government Department will, when opportunity arises, also support this Bill and introduce it as a legislative measure.

On June 26th, 1941, the Government Bill was introduced. The Lord President of the Council, the Chancellor of the Exchequer, the Secretary of State for Scotland, the Attorney-General and

Mr. Peake, Under-Secretary, Home Office, supported the Bill which, in addition to repealing the stamp and licence duties, proposed to regulate the sale of medicines, to prohibit advertisements relating to certain medical matters and at the same time effect some minor amendments to the Pharmacy and Poisons Act, 1933. During the Committee stage of the Bill the following additional clauses were proposed, but the first was withdrawn and the second negatived on a vote:—

(a) No person shall sell or advertise under a fancy proprietary name any preparation having essentially the same composition as preparations listed in the current editions of the British Pharmacopœia or of the British Pharmaceutical Codex.

(b) No person other than a person authorised under sub-section (1) of section seven (section 12 of the Act) shall sell any article comprising a substance recommended as a medicine under a proprietary designation unless it was, at the time of the passing of this Act, being sold under that designation.

Royal Assent was given to the Bill on August 7th, 1941. The essential provisions as they affect the sale of medicines are:—

Advertisements. Advertisements relating to Bright's disease, cataract, diabetes, epilepsy or fits, glaucoma, locomotor ataxy, paralysis or tuberculosis in terms which are calculated to lead to the use of the articles for the purpose of the treatment of human beings are prohibited (Section 8). Advertisements published by certain public bodies and by voluntary hospitals are excluded from the prohibition. A defence is provided to allow publication of such advertisements to a restricted group of persons which includes registered medical practitioners, registered pharmacists, authorised sellers of poisons and nurses and those undergoing training for such registration. Permission has since been given by the Minister of Health, under powers conferred on him, "permitting the publication of any advertisement referring to insulin in terms which are calculated to lead to its use for the purpose of the treatment of human beings for diabetes, but not otherwise referring to any article, or articles of any description, in such terms as are mentioned in subsection 1, section 8, of the Pharmacy and Medicines Act, 1941." Advertisements referring to articles in terms which are calculated to lead to the use of the articles for procuring the miscarriage of women are prohibited by Section 9 of the Act, which does not contain the defence provided for the preceding section, although Section 10 provides a defence restricted to advertisements in technical publications.

Disclosure of Composition. Any substance which is referred to in terms which are calculated to lead to the use of the substance for the prevention or treatment of any ailment, infirmity or injury affecting the human body must have a quantitative disclosure of composition.

An exception is provided in the case of an article prepared for a particular person if it is prescribed for the needs of that person. This provision allows the supply of counter-prescribed medicines complying with the stated terms of exemption and consequently disclosure is not necessary in such cases.

Selection of Name. Misleading and unscientific terms must not be used. The Act requires the Poisons Rules procedure to be followed for those ingredients which are poisons. If not a poison the British Pharmacopœia or British Pharmaceutical Codex titles must be used where applicable. Either the English, full Latin, precise abbreviated form or synonym may be used, but not chemical formulæ.

Where the preceding methods cannot be applied the recognised and accepted scientific name or other name which gives a true description of the ingredient must be used.

Statement of Quantities. No quantity need be stated where the substance as a whole has an appropriate description as indicated above. The amount of an ingredient is to be stated as the approximate percentage or the approximate quantity in each container. An alternative is provided, e.g., in the case of tablets and powders, where the amount in each portion may be stated. Unless the article is a poison it is not necessary to state the number of "portions" in each package. The disclosure must be placed on the immediate container, e.g., bottle, box or each individual wrapper where single powders are supplied from bulk packings. An exception to the disclosure requirement is made if the substance is referred to in terms which are not "terms which give a definite indication that the substance is intended to be used as, or as part of, a food or drink, and not as, or as part of, a medicine."

Restriction on Sales. All retail sales of recommended medicines must be made from a shop and are restricted to certain classes of persons. The seller may be a doctor, dentist or authorised seller of poisons or, if not a member of one of these classes, one who has served a regular apprenticeship and on August 7th, 1941, was carrying on the retail sale of drugs on his own account with the business, so far as it concerns the sale of drugs, under his personal control. Sales by an authorised seller of poisons are restricted to premises registered under Part 1 of the Pharmacy and Poisons Act 1933. Sales of a dried, crushed or comminuted plant or a mixture of such plant or plants with water, also natural, or artificial imitations of natural mineral waters can be made by all traders provided the sale is made from a shop. A person not authorised as described above may sell proprietary medicines subject to certain limitations, the effect of which practically restricts the sale of non-proprietary recommended *B.P.* and *B.P.C.* preparations to the authorised class of sellers. The Act defines "proprietary designation" in terms which, in effect, bring the article within the scope of the Act if the seller describes it, or if the article is labelled, in such a way as to indicate the goods of a particular person.

FORMULÆ OF PROPRIETARY MEDICINES

Owing to the legislation which now makes compulsory the disclosure of formulæ on all preparations sold for medicinal use,

we are able to provide fuller information on the composition of so-called "patent medicines." The following list is composed of a representative selection of nationally advertised remedies supplied through the normal wholesale channels as being those in most frequent demand. In most cases, the name of the manufacturer is given together with the principal claims and uses of each preparation. *All information relating to both formulæ and uses is stated precisely in the manner in which it appears on the label of the container or in accompanying literature.* An indication of the recommended dosage is also given.

The disclosure of formulæ has abolished the principal criterion by which ethical remedies were formerly distinguished. Although the disclosure is frequently vague and sometimes misleading, to a degree sufficient to prevent the production of an exact imitation, secret remedies are to-day non-existent. For this reason the question as to whether a product is ethical or non-ethical, whether it should be described in Volume I or Volume II of the *Extra Pharmacopœia*, can no longer be determined by reference to the amount of information available as to its composition. A more practical discrimination is made possible by considering the method of distribution, i.e., whether a preparation is sold to the public by advertisement and without reference to the requirements of the individual patient or whether it is a product recommended or prescribed by doctors or pharmacists for the treatment of individual patients.

Adrax Tablets (*W. B. Cartwright Ltd., Rawdon*). "A scientifically devised double treatment restoring to the kidneys and bladder their normal functions. A cure for backache, bladder weakness, lumbago, rheumatism, acidity, bladder irritation." *Formula*:—*White tablets*:—Pot. Bicarb. gr. 14, Sod. Acet. gr. 11, Pot. Cit. gr. 11, Acid. Citric. gr. 0.7. *Brown tablets*:—Aloes gr. 1, Potas. Nitrates gr. 1, Asafoetida gr. 1, Methylthionin Hydroch. gr. $\frac{1}{2}$, Ol. Juniper min. $\frac{1}{2}$, Capsicum gr. $\frac{1}{2}$, Excipient q.s.

[P2] **Aero-Cotarol** (*Maw, Son & Sons, Barnet*). "A scientific germ-destroying vaporant of remarkable potency. For the treatment and prevention of influenza, bronchitis, asthma, catarrh, whooping cough and all respiratory disorders." *Formula*:—Contains 44.5% w/w of cresols.

Agarol Compound (*William R. Warner & Co. Ltd., London*). "A perfectly homogenised emulsion. Indicated in constipation." *Formula*: Active constituents: Paraff. Liq. 25% v/v, Phenolphthal. 1.3% w/v, Agar 0.2% w/v. *Dose*: $\frac{1}{2}$ to 1 tablespoonful. Children, $\frac{1}{2}$ to 2 teaspoonfuls.

Agocholine Soluble Granules (*Bengué & Co. Ltd., Wembley*). "A valuable remedy in jaundice, congestion of the liver and gall bladder, and subacute and chronic cholecystitis whether stones are present or not. Relieves the local and general symptoms of hepatic origin, such as nausea, vertigo, migraine, urticaria, anorexia and constipation due to biliary insufficiency." *Formula*:—Approx. Percentages, Peptone 6.2, Mag. Sulph. 31.4, Saccharum Alb. 62.4. *Dose*: 1 to 3 teaspoonfuls.

Agonsair (*Agonsair Co. Ltd., London*). "For destroying nits and vermin. Harmless in nature." *Formula*:—Active Ingredients: Quassia Lignum 7.0%, Ol. Rosmarini 0.5%, Sod. Borate 1.5%, Spt. Meth. Indust. 15.0%, Ext. Quassia 0.5%.

Alasil Brand (*A. Wander Ltd., London*). "For rheumatism, influenza, colds, headache, neuralgia, toothache and for relieving pain generally." *Formula*:—5 grs. Acetyl-Salicylic Acid, 6 grs. Alocol (Colloidal Hydroxide of Aluminium) and $1\frac{1}{2}$ grs. of Calcium Phosphate Bibasic.

Alka-Zane (*W. R. Warner & Co. Ltd., London*). "Alkalizer, antacid, diuretic. Alka-Zane promotes the elimination of those acid products of metabolism, the excessive formation and retention of which in the body may

lead to acidosis, acidæmia and similar conditions." *Formula*:—Sod. Bicarb. 48%, Pot. Bicarb. 7%, Ac. Cit. 24%, Soda Cit. 12%, Calc. Phosph. 3.5%, Mag. Phosph. 3.5%, Calc. Glycerophosph. 1.6%. *Dose*: 1 heaped teaspoonful.

Alkia Saltrates (*Saltrates Ltd., London*). "A positive and natural corrective for stomach, blood, liver, kidney, bladder and intestinal disorders. Unrivalled as a specific for rheumatism, catarrhal affections, dyspepsia, gout, etc." *Formula*:—Magnes. Sulph. Exsicc. 27.57%, Sodii Sulph. Exsicc. 25.73%, Sodii Chlorid. 1.38%, Lithii Carbonas. 0.69%, Saccharin 0.06%, Effervescent base to 100.00%. *Dose*: 1 to 3 teaspoonfuls.

Allcock Brand Porous Plaster (made in U.S.A.; European agency:—*The Allcock Manufacturing Company, Birkenhead*). [P1] **Wright's Coal Tar Vaporizing Liquid** (*Wright, Layman & Umney Ltd., London*). "Specially prepared for use in Wright's Coal Tar Inhaler." *Formula*:—Pix Carbonis B.P.C. 0.25, Olea Essentialia 10.0, Naphthalenum 1.5, Cresol ad 100.0.

Wyamin Brand Capsules (*John Wyeth & Brother Ltd., London*). "Containing vitamins A, B, C, D and nicotinic acid. Biologically standardised." *Formula*:—Vitamin A 6000 Int. Units, Vitamin D 900 Int. Units, Vitamin B 100 Int. Units, Vitamin B₂ Complex containing Lactoflavin 50 gamma, Vitamin C 100 Int. Units, Nicotinic Acid 5 mg. *Dose*: 1 to 2 capsules.

Yadil Antiseptic (*Yadil (1935) Ltd., London*). "The internal antiseptic. It disinfects the human system internally and externally, and being highly diffusive it is of great value in obscure infections where other antiseptics fail." *Formula*:—Glycerol 3.75%, Paraformaldehyde 1.25%, Thymol 0.0625%, Oleum Allii Essentiale 0.008%, Aqua Thymolis (Sat. Sol.) 60.00%.

Yadil Antiseptic Ointment (*Yadil (1935) Ltd., London*). "Containing 5% of Yadil Antiseptic. It is ideal for all conditions where a healing and soothing unguent is needed." *Formula*:—Active ingredients: Glycerol 0.20%

Paraformaldehyde 0.06%, Thymol 0.006%, Oleum Allii Essentiale 0.004%, Adeps. Lanæ, Paraffin Mollæ equal parts up to 100.00%.

Yadil Antiseptic Pills (*Yadil* (1935) *Ltd., London*). *Formula*:—Glycerol 11.25%, Paraformaldehyde 3.75%, Thymol 0.36%, Oleum Allii Essentiale 0.024%, Amylum 40.00%, Kaolinum up to 100.00%. *Dose*: Infants, 1 pill; Children, 2 pills; Adults, 3 pills.

Yadil Pastilles (*Yadil* (1935) *Ltd., London*). "Cleanse the throat and mouth of bacillary infection; invaluable to speakers." *Formula*:—Active ingredients: Paraformaldehyde 0.153%, Thymol 0.002%, Ol. Allii Essentiale 0.001%, Glycerol 0.457%, Ol. Limonis 0.167%, Acid. Citric. 1.785%, Pastille Base ad 100.0%.

Yadlets (*Yadil* (1935) *Ltd., London*). "Yadil antiseptic tablets." *Formula*:—Glycerol 15.00%, Paraformaldehyde 5.00%, Thymol 0.50%, Oleum Allii Essentiale 0.032%, Amylum 40.00%, Kaolinum up to 100.00%.

Yeast-Vite Tablets (*Yeast-Vite Laboratories, Watford*). "The lightning pick-me-up. The safe and wonderful treatment of medicinal yeast." *Formula*:—Cerevis. Ferment. B.P.C. 44.34%, Caffein 2.82%, Acetphenetidin 16.52%, Pot. Brom. 4.13%, Sod. Bicarb. B.P. 12.17%, Mag. Carb. Pond. 17.48%, Caryoph. 2.54%. *Dose*: 2 tablets.

Yestamin (*English Grains Co. Ltd., Burton-on-Trent*). "A pure food product containing the valuable vitamin B₁ and B₂."

Yestamin Pure Yeast Tablets (*English Grains Co. Ltd., Burton-on-Trent*). "Extremely rich in vitamin B. Guaranteed free from drugs." *Formula*:—These tablets are pure dried yeast with a fractional amount of innocuous gum for binding. Pure yeast tablets 5.5 gr. *Dose*: 2 or 3 tablets.

Zam-Buk Brand Ointment (*Zam-Buk Mfg. Co., Leeds*). "For cuts, bruises, scratches, burns, scalds, sprains, eczema, ulcers, bad legs, rashes, pimples, piles, chafings, chapped hands, chilblains, cold sores, cold-on-the-chest, insect-bites." *Formula*:—Resin Pini Palust. 14.40%, Paraffin Dur. 21.50%, Paraffin Mollæ 53.40%, Flor Camphoræ 1.85%, Ol. Eucalypt. Globul 7.56%, Ol. Thymi Vulgar 0.93%, Ext. Chlorophylli 0.03%, Ol. Sassaf. Officin 0.33%.

Zam-Buk Brand Suppositories (*Zam-Buk Mfg. Co., Leeds*). "For the direct application to internal hæmorrhoids (or piles)." *Formula*:—Thymol 0.2, Camphor 1.0, Menthol 0.5, Chlorophyll 0.5, Ol. Eucalyptus 1.0, Ol. Theobrom. 82.45, Paraffin. Dur. 9.22, Resina 5.13, per cent.

Zee-Kol Brand Blood Tonic Pills (*The Shavex Zee-Kol Co. Ltd., London*). *Formula*:—P. Aloes Barb. gr. 50, P. Saponis gr. 0.18, P. Zingib. gr. 0.55, Sacch. Alb. gr. 0.27. *Dose*: 3 to 4 pills.

Zee-Kol Brand Ointment (*The Shavex Zee-Kol Co. Ltd., London*). "For ulcers, piles, rheumatism, bad legs, sores, burns, cuts, bruises, eczema, chilblains, and all forms of skin diseases." *Formula*:—Adeps Lanæ Hydrosus 77.00, Acid Boric 5.40, Zinci Oxidi 8.20, Sulphur 2.50, Colophonium 2.50, Ol. Eucalypt Glob. 3.40.

[P1] **Zom Brand Pile Ointment** (*Arthur H. Cox & Co. Ltd., Brighton*). *Formula*:—Ext. Hamam. Liq. 5.60%, Gall. 13.28%, Acid Boric. 2.07%, Opium Pulverat B.P. w/w 1.87%, Adeps Lan. 26.56%, Paraff. Moll. Flav. 49.79%, Ol. Thym. Alb. 0.83%.

Zotal Brand Liniment (*Burgoyne Burbidges & Co. Ltd., London*). "Relieves rheumatism, lumbago, sciatica, muscular pains, stiffness of the joints, neuralgia, colds, sore throat, chilblains, sprains, cramp, neuritis, bronchitis, cough, asthma." *Formula*:—Capsici Fruct. 1.25, Ol. Camph. Essent. ad 100. Colour, Scarlet Red and Oil Brown q.s.

Zox (*Zox Mfg. Co., London*). "Death to pain. A real cure for toothache, neuralgia, headache, sciatica and nerve pains." The composition of this preparation was not disclosed. *Dose*: 1 powder.

Zubes (*F. W. Hampshire & Co. Ltd., Derby*). "For throat and chest." *Formula*:—Approx. percentages of ingredients: Menthol .3, Marrubium .6, Bals. Tolu .07, Ol. Anisi .19, Gingerin .02, Benzoinum .06, Ol. Menth. Pip .125, Benzyl Benzoas .15, Tinct. Capsici .18, Tussilago .03, Sucrosum et Glucosum Liq. ad 100.

NOMENCLATURE OF ORGANIC COMPOUNDS

The ever increasing number of organic compounds necessitates the adoption of a systematic scheme of nomenclature to obviate the naming of a compound according to the whim of its discoverer. The first serious attempt to provide a universal system was made by the International Congress at Geneva in 1892. Many generalisations found acceptance and such classifications as those of Beilstein and Chemical Abstracts are based upon it. In 1931 (*J. Chem. Soc.*, p. 1607) a Definitive Report of the Committee for the Reform of Nomenclature in Organic Chemistry was issued which aimed at the preservation of common usage as much as possible whilst achieving some simplification. Thus the use of many names which were established by practice was consolidated. A completed system for international adoption has not been evolved and some idea of the difficulties to be overcome may be derived from the knowledge that there are over 3300 different ring systems known at the present time. However, sufficient stability in the principles of naming has been attained by virtue of these efforts that non-ambiguous names which indicate the constitution of the compound can be coined for all organic substances.

The general principle underlying the scheme is the naming of all compounds as derivatives of a comparatively small number of parent structures, such structures being indicated by a termination specific to them. Thus the terminations "*ane*" and "*ol*" indicate a paraffinoid and a hydroxy compound respectively.

For the purpose of this explanation of the principles of nomenclature, the following classification of organic compounds is used.

ALIPHATIC COMPOUNDS

Hydrocarbons. The names of all saturated hydrocarbons (C_nH_{2n+2}) end in *ane*: *methane* (CH_4), *ethane* (C_2H_6), *propane* (C_3H_8), *butane* (C_4H_{10}), higher homologues being named according

to the number of carbon atoms in the compound: *pentane* (C_5H_{12}), *hexane* (C_6H_{14}), *heptane* (C_7H_{16}), etc. Branched chain compounds are regarded as derivatives of a normal, or unbranched chain substance, the position of substitution being indicated by numbering the carbon atoms comprising the normal compound. The names of such compounds must be based upon that of the *longest* unbranched chain present and the numbers chosen so that they are the lowest possible.

The above compound contains a continuous chain of eight carbon atoms and is therefore named as a derivative of octane: *2-methyl-4-isopropyl-5-ethyl-octane*. If the octane chain were numbered from the other end the substituent groups would fall on carbon atoms 4, 5 and 7, which are higher numbers than 2, 4 and 5 and therefore are not used. Should the compound contain several functional groups the longest chain containing the principal functional group or greatest number of double or triple linkages or other substituents is chosen as the basis for the name.

Unsaturated Hydrocarbons. In those containing one double bond the termination *ane* of the parent hydrocarbon is changed to *ene*; similarly those containing two, three, or many double bonds are termed respectively *dienes*, *trienes*, or *polyenes*. The double bond is indicated by the Greek letter Δ and its position in the molecule is fixed by numbering the carbon skeleton of the parent hydrocarbon

Similarly the acetylenic hydrocarbons (triple bond) have the termination *ane* replaced by *yne*: *diyne*, *triyne*, etc., such as, $CH \equiv C-CH_2-CH_2-C \equiv CH$, 1 : 5-hexadiyne.

Throughout this section names of functions and substances used as examples of nomenclature appear in *italic type*, so as to give emphasis and to assist the reader. Normally these names are printed in Roman type and only those parts which indicate the existence of isomeric forms are italicised (*see Use of Italics*, p. 472). Such portions which normally are italicised are shown in Roman type.

Simple and Complex Functions. The method illustrated by the foregoing examples is applicable to a vast array of chemical compounds. Substances of simple function contain an active grouping of one kind only, which may be repeated in the molecule, and their names are derived from the longest unbranched chain containing that function with the termination modified to indicate the constitution of the function. In compounds containing more than one kind of function (complex functions) the termination expresses the principal function, the others being indicated by appropriate prefixes. The groupings $-\text{CHO}$, $-\text{CN}$, and $-\text{COOH}$ are regarded as functions, their carbon atoms not being numbered, but the numbering commences on the carbon carrying that group.

Tables I and II contain the commoner functional groups together with the prefixes and suffixes used.

TABLE I

| Function | Prefix | Suffix |
|--|------------------------------------|--|
| Acid, $-\text{COOH}$ | <i>carboxy</i> | <i>carbonic (carboxylic)</i> |
| $\text{R}-\text{C} \begin{smallmatrix} \text{O} \\ \parallel \\ \text{NH}_2 \end{smallmatrix}$ | | <i>carbonamide</i> |
| $-\text{AsO}(\text{OH})_2$ | <i>arsono</i> | <i>arsonic</i> |
| Alcohol or phenol | <i>hydroxy</i> | <i>ol</i> |
| Aldehyde | <i>aldo, oxo</i> | <i>al</i> |
| Amine | <i>amino</i> | <i>amine</i> |
| Alkoxy (Ether oxide) | <i>methoxy, ethoxy, etc.</i> | |
| Pentavalent N | | <i>onium (open chain)</i> <i>inium (closed chain)</i> |
| Cyanide | <i>cyano</i> | <i>carbonitrile or nitrile</i> |
| Ketone | <i>keto</i> | <i>one</i> |
| $-\text{SOOH}$ | <i>sulphino</i> | <i>sulphinic</i> |
| $-\text{SO}_2\text{OH}$ | <i>sulpho</i> | <i>sulphonic</i> |
| Hydrazine | <i>hydrazino</i> | <i>hydrazine</i> |
| Double bond | | <i>ene</i> |
| Triple bond | | <i>yne</i> |
| Mercaptan | <i>mercapto</i> | <i>thiol</i> |
| Urea | <i>ureido</i> | <i>urea</i> |

The principles upon which the names for many of the above radicals are derived are explained in the following table.

Radicals derived from hydrocarbons, etc.

(a) *from hydrocarbons:*

Univalent—Substitute *yl* for *ane*.
 Substitute *enyl* for *ene*.
 Substitute *ynyl* for *yne*.
 Substitute *dienyl* for *diene* (etc.).

Bivalent (by loss of 2H from same carbon)—
 Substitute *ylidene* for *ane*.

TABLE II

| Function | Prefix | Function | Prefix |
|---|--------------------------------------|-------------------------------------|--------------------------|
| Halogen | <i>chloro, bromo, etc.</i> | $-C_{14}H_9$ | <i>anthryl</i> |
| $-NO$ | <i>nitroso</i> | $-C_{14}H_7$ | <i>phenanthryl</i> |
| $-NO_2$ | <i>nitro</i> | $-C(C_6H_5)_3$.. | <i>triphenylmethyl</i> |
| $-N \begin{smallmatrix} \diagup N \\ \\ \diagdown N \end{smallmatrix}$ | <i>azido, triazo</i> | $-CH_2-CH_2-CH_2-$ | <i>trimethylene</i> |
| $-N=N-$ | <i>azo</i> | $-CH=CH-$ | <i>vinylene</i> |
| $-As=As-$ | <i>arseno</i> | $-C_6H_4-$ | <i>phenylene</i> |
| $-N=N-(OH, Cl,$ etc.) | <i>diazo</i> | $-CH_2-$ | <i>methylene</i> |
| $-N-N-$ | <i>azoxy</i> | $=CH-CH_3$ | <i>ethylidene</i> |
| $\begin{smallmatrix} \\ O \end{smallmatrix}$ | | $=CHC_6H_5$ | <i>benzylidene</i> |
| $-NH_2$ | <i>amino</i> | $-CH_2-CO-CH_3$.. | <i>acetonyl</i> |
| $>NH$ | <i>imino</i> | $-CH_2-CO-C_6H_5$.. | <i>phenacyl</i> |
| $=NOH$ | <i>oximino,</i> <i>isonitroso</i> | $-CHO$ | <i>aldehydo</i> |
| $-NH-OH$ | <i>hydroxylamino</i> | $-COCH_3$ | <i>acetyl, acet-</i> |
| $-NH-NH-$ | <i>hydrazo</i> | $-CO-C_6H_5$ | <i>benzoyl</i> |
| $-NH-N=N-$ | <i>diazoamino</i> | $-CO-C_6H_4-OH$ (1 : 2) | <i>salicyloyl</i> |
| $-NH-N=N-$ (cyclic) | <i>azimino</i> | $-CO-CH=$ CHC_6H_5 | <i>cinnamoyl</i> |
| $-NH-C_6H_5$ | <i>anilino</i> | $-CO-C_{10}H_7$ | <i>naphthoyl</i> |
| $-NH-C_6H_4-CH_3$ | <i>toluidino</i> | $-CO-CO-$ | <i>oxalyl</i> |
| $-NH-CO-NH_2$.. | <i>ureido</i> | $-CO-CH_2-CO-$.. | <i>malonyl</i> |
| $-C(=NH)-NH_2$ | <i>guanyl</i> | $-CO-CH_2-NH_2$.. | <i>glycyl</i> |
| $-NH-C(=NH)-$ NH_2 | <i>guanidino</i> | $-CO-CHNH_2-$ CH_3 | α - <i>alanyl</i> |
| $-S-$ | <i>thio</i> | $-CO-CH_2-NH-$ $CO-C_6H_5$ | <i>hippuryl</i> |
| $-SO-$ | <i>thionyl</i> | $-C_4H_5O$ | <i>furyl</i> |
| $-SCN$ | <i>thiocyano</i> | $-C_4H_5S$ | <i>thienyl</i> |
| $=SO_2$ | <i>sulphonyl</i> | $-CH_2-C_4H_5O$.. | <i>furfuryl</i> |
| $-CH=CH_2$ | <i>vinyl</i> | $-C_4H_5NH$ | <i>pyrryl</i> |
| $-CH=CH-CH_3$.. | <i>propenyl</i> | $-C_5H_4N$ | <i>pyridyl</i> |
| $CH_2-CH=CH_2$ | <i>allyl</i> | $-HgOH$ | <i>hydroxymercuri</i> |
| $-C\equiv CH$ | <i>ethinyl</i> | $-HgCl$ | <i>chloromercuri</i> |
| $-CH_2-C\equiv CH$.. | <i>propargyl</i> | $-C_6H_5$ | <i>phenyl</i> |
| $-C_6H_4-CH(CH_3)_2$ | <i>lumyl</i> | $-C_6H_4-CH_3$ | <i>tolyl</i> |
| $-C_6H_3(CH_3)_3$ (1 : 3 : 5) | <i>mesityl</i> | $-CH_2-C_6H_5$ | <i>benzyl</i> |
| $-CH=CHC_6H_5$.. | <i>styryl</i> | $-CH_2-C_6H_4-OH$ | <i>salicyl</i> |
| $-CH_2-CH=$ CHC_6H_5 | <i>cinnamyl</i> | $-CH_2-C_6H_4-OCH_3$ | <i>anisyl</i> |
| $-C_{10}H_7$ | <i>naphthyl</i> | $-CH_2-C_6H_4-CH_3$ | <i>xyllyl</i> |
| | | O (in ring) | <i>oxa</i> |
| | | N (in ring) | <i>aza</i> |
| | | S (in ring) | <i>thia</i> |

Trivalent (by loss of 3H from the same carbon)—
Substitute *ylidyne* for *ane*.

Bivalent (by loss of 1H from each of two terminal carbons)—
Substitute *ylene* for *ane*.

(b) *from acids*:

By loss of OH from COOH—Substitute *yl* for *ic*.

(c) *from alcohols*:

Names universally adopted are retained: *Methanol* and *ethanol* are in use as well as methyl and ethyl alcohol. The amyl alcohols serve to illustrate the systems used. The alternative system is based upon naming all alcohols as derivatives of methyl alcohol which is then called *carbinol*.

This system is sometimes convenient for secondary and tertiary alcohols.

Primary alcohols contain the group $\text{—CH}_2\text{—OH}$

Secondary alcohols contain the group >CH—OH

Tertiary alcohols contain the group >C—OH

AMYL ALCOHOLS ($\text{C}_5\text{H}_{11}\text{OH}$)

| | Systematic Nomenclature | Alternative Name |
|---|---|--|
| $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{—OH}$ | <i>Pentan-1-ol</i> or <i>Pentanol-1</i> | |
| $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{—CHOH—CH}_3$ | <i>Pentan-2-ol</i> | <i>Methyl-n-propyl-carbinol</i> |
| $\text{CH}_3\text{—CH}_2\text{—CHOH—CH}_2\text{—CH}_3$ | <i>Pentan-3-ol</i> | <i>Diethylcarbinol</i> |
| $\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{—CH—CH}_2\text{—CH}_2\text{OH} \end{array}$ | <i>3-Methylbutan-1-ol</i> | |
| $\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{—CH—CHOH—CH}_3 \end{array}$ | <i>3-Methylbutan-2-ol</i> | <i>Methylisopropyl-carbinol</i> |
| $\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{—C(OH)—CH}_2\text{—CH}_3 \end{array}$ | <i>2-Methylbutan-2-ol</i> | <i>Dimethylethylcarbinol</i> <i>Amylene hydrate</i> |
| $\begin{array}{c} \text{CH}_3\text{—CH—CH}_2\text{—CH}_3 \\ \\ \text{CH}_2\text{OH} \end{array}$ | <i>2-Methylbutan-1-ol</i> | |
| $\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{—C—CH}_2\text{OH} \\ \\ \text{CH}_3 \end{array}$ | <i>2-Dimethylpropan-1-ol</i> | |

If sulphur replaced the oxygen in the above alcohols the names of the compounds would end in *thiol* instead of *ol*. Polyhydric alcohols are named by interposing *di*, *tri*, *tetra*, etc., between the name of the parent hydrocarbon and the suffix *ol*.

Thus, $\text{CH}_2\text{OH}-\text{CHOH}-\text{CH}_2\text{OH}$ is *Propantriol* (Glycerin) and $\text{CH}_2\text{OH}-\text{CHOH}-\text{CHOH}-\text{CH}_2\text{OH}$ is *Butantetraol* (Erythritol).

Ethers. (a) Simple ethers in which the two radicals carried by the oxygen atom are the same are named as follows:—*Dimethyl ether*, $\text{CH}_3-\text{O}-\text{CH}_3$; *Diethyl ether*, $\text{C}_2\text{H}_5-\text{O}-\text{C}_2\text{H}_5$. When either radical carries a substituent the numbering starts from the carbons next to the oxygen.

When two similar parts of a molecule are numbered they are differentiated by the use of 1 and 1', 2 and 2', etc.

(b) Mixed ethers, in which the two radicals carried by the oxygen atom are different are named as alkoxy derivatives of a hydrocarbon.

Sulphides, $\text{R}^1-\text{S}-\text{R}^2$, are named in the same manner as ethers, substituting *thio* for *oxy*, or *thioether* for *ether*.

Sulphoxides and **Sulphones** are similarly treated, substituting *sulphinyl* and *sulphonyl* respectively for *oxy*. Thus $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{SO}-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_3$ is (1-*Propylsulphinyl*)-butane and $\text{CH}_3-\text{SO}_2-\text{CH}_2-\text{CH}_3$ is *Methylsulphonylthane*.

On this plan the sulphone hypnotics would receive the names indicated below but the alternative system based upon methane as the parent is equally non-ambiguous.

2 : 2-Di(ethylsulphonyl)propane, or
Diethylsulphonyldimethylmethane
(Sulphonal)

2 : 2-Di(ethylsulphonyl)butane, or
Diethylsulphonylmethylethylmethane
(Methylsulphonal)

The coined names are poor as they would suggest an aldehydic constitution: again the term methylsulphonal is ambiguous and could be applied equally well to the following isomeric substance.

2-Ethylsulphonyl-2-propyl-
sulphonylpropane

Acids. The established names are used, otherwise the following terminations are added to the name of the hydrocarbon which is considered to be substituted.

| Substituent | Suffix |
|--|-----------------------------|
| -COOH | { <i>carboxylic acid</i> |
| -CONH ₂ | <i>carbonic acid</i> |
| -COSH | <i>carbonamide</i> |
| -CSOH | <i>carbothioic</i> |
| -CSSH | <i>carbothionic</i> |
| -C $\begin{smallmatrix} \text{NH}_2 \\ \diagup \\ \text{Cl}_2 \end{smallmatrix}$ | <i>carbodithioic</i> |
| -C $\begin{smallmatrix} \text{NH} \\ \diagup \\ \text{Cl} \end{smallmatrix}$ | <i>carbonamidochloride</i> |
| -C $\begin{smallmatrix} \text{NH} \\ \diagup \\ \text{NH}_2 \end{smallmatrix}$ | <i>carbonimidochloride</i> |
| -C $\begin{smallmatrix} \text{NOH} \\ \diagup \\ \text{OH} \end{smallmatrix}$ | <i>carbonamidine</i> |
| -C $\begin{smallmatrix} \text{NO} \\ \diagup \\ \text{NH}_2 \end{smallmatrix}$ | <i>hydroxamic acid</i> |
| -C $\begin{smallmatrix} \text{O} \\ \diagup \\ \text{N}_2 \end{smallmatrix}$ | <i>carbamidoxime</i> |
| -CH ₃ -C $\begin{smallmatrix} \text{NH}_2 \\ \diagup \\ \text{Cl}_2 \end{smallmatrix}$ | <i>acid azide</i> |
| -CH ₃ -C $\begin{smallmatrix} \text{NH} \\ \diagup \\ \text{Cl} \end{smallmatrix}$ | <i>acetamidochloride</i> |
| -CH ₃ -C(=NH)NH ₂ | <i>acetimidochloride</i> |
| -CH ₃ -C $\begin{smallmatrix} \text{NOH} \\ \diagup \\ \text{OH} \end{smallmatrix}$ | <i>acetamidine</i> |
| -CH ₃ -C $\begin{smallmatrix} \text{NOH} \\ \diagup \\ \text{NH}_2 \end{smallmatrix}$ | <i>acetohydroxamic acid</i> |
| -CH ₃ -CH ₂ -C $\begin{smallmatrix} \text{O} \\ \diagup \\ \text{N}_2 \end{smallmatrix}$ | <i>acetamidoxime</i> |
| | <i>propionazide</i> |

The name carbamic acid is given to amino-formic acid, NH₂·COOH, esters of which are generally classified as urethanes.

Ethyl carbamate
(Urethane)

Aldehydes are designated by the suffix *al* to the name of the parent hydrocarbon: thioaldehydes by *thial*. The acetals are named as dialkoxy-derivatives of the paraffin.

Ketones receive the termination *one*; diketones, triketones, and thioketones are indicated by the suffixes *dione*, *trione*, and *thione* respectively.

Diketones in which the two functions occupy neighbouring carbon atoms are generically called α -diketones; those in which the two functions are separated by one, two, three, etc., carbon atoms are β , γ , δ , etc., diketones.

Nitrogenous bases are exclusively indicated by the suffix *ine*: aliphatic quinquivalent nitrogen compounds change the *ine* into *onium*: cyclic quinquivalent nitrogen compounds change *ine* into *inium*, or *ole* into *olium*.

Sugars always end in *ose*. The systematic names based upon their cyclic formulæ are derived from the furan and pyran nuclei, the specific name indicating the particular stereoisomeride, glucose thus becomes *glucopyranose*, and fructose, *fructopyranose*.

The names of disaccharides indicate whether the α or β form of the monosaccharide is concerned in the linking: a numeral is used to identify the carbon of the other monosaccharide occupied with the union. The carbon atoms of the monosaccharides are numbered starting from the reducing group.

β -Glucose-4- α -glucoside or β -Glucopyranose-4- α -glucopyranoside
(Maltose)

Similarly, lactose is *glucose-4-β-galactoside*, and sucrose is *α-glucopyranose-1-β-fructofuranoside*.

The terms *monosaccharide*, *disaccharide*, *trisaccharide*, *polysaccharide* indicate the number of sugar units in a compound. Individual monosaccharides are called *pentoses*, *hexoses*, etc., according to the number of carbon atoms they contain.

The term *glycoside* is used to denote all ethers of the reducing group, whilst *glucoside*, *mannoside*, *fructoside*, etc., denote the ether of that particular hexose.

Ascorbic acid provides an interesting example of nomenclature related to this group.

In ascorbic acid, "*l-gulo*" signifies the same stereochemical configuration as *l-gulose*; "*furanolactone*" indicate *γ*-lactone structure; the 3-keto group exists in the enolic form.

General Guide to Numbering

Arabic numerals are used, the lowest numbers being given to the triple bond, the double bond, the principal function or the atoms or radicals which are denoted by prefixes. Positions in side chains are indicated by letters starting from the point of attachment to the nucleus, the letters and the name of the chain being given in parenthesis. The prefixes *di-*, *tri-*, *tetra-*, etc., are used before simple expressions (diethylamine), whilst *bis-*, *tris-*, *tetrakis-*, etc., are used before complex substituents.

$\text{CH}_3\text{-CH}(\text{NHCH}_3)\text{-CH}_2(\text{NHCH}_3)$ $(\text{CH}_3)_2\text{N-CH}_2\text{-CH}_2\text{-N}(\text{CH}_3)_2$
 1:2-bis(Methylamino)propane bis(Dimethylamino)ethane

The prefix *bi-* is only used for the doubling of a radical or compound, e.g., *biphenyl*, $\text{C}_6\text{H}_5\text{-C}_6\text{H}_5$.

Complex Functions

In compounds containing several radicals of different chemical character the principal function is indicated by the termination and the other functions by appropriate prefixes. A few examples will serve as illustrations.

2 : 2'-Dichlorodiethylsulphide
or Di(2-chloroethyl) sulphide

2-Trichloromethylpropan-2-ol
(Chlorbutol)

Dimethylaminomethylethyl-
methylcarbinol
(Benzoate is amylocaine base)

bis(Dimethylaminomethyl)-
ethylcarbinol
(Benzoate is amydricaine base)

α -Bromo- α -ethylbutyrylurea
(Carbromal)

2-Chlorobutadiene
(Chloroprene)

3 : 7-Dimethyl- Δ^2 , 6-octadienal
(Citral)

2-Hydroxy-2'-ethoxydiethylether
(Diethyleneglycolmonoethylether)

2-Hydroxypropane-1 : 2 : 3-
tricarboxylic acid
(Citric acid)

2 : 2 : 3-Trichlorobutan-
1 : 1-diol
(Butylchloral hydrate)

Δ^1 -Butylene-2 : 4-dicarboxylic acid

2-Methylbutadiene
(Isoprene)

HOMOCYCLIC AROMATIC COMPOUNDS

The chief homocyclic systems are as follows:—

Benzene

Naphthalene

Anthracene

Phenanthrene

The symmetry of the naphthalene and the anthracene formulæ makes possible the use of alternative designations for specific positions. The α -, β -, designations are mainly used for mono-substitution derivatives just as the *ortho* (*o*), *meta* (*m*), and *para* (*p*) prefixes may be used for the di-substitution products of benzene. Other cyclic structures are illustrated below, some of the names being based upon those given above. The nomenclature of naphthalene, anthracene and phenanthrene derivatives and those of other cyclic structures are described under "Condensed Nuclei."

Benzene Derivatives. In polysubstituted substances numbering commences with the principal functional group. *Cresols* are considered as hydroxy-derivatives of toluene, hence the numbering commences with the methyl group. If considered as a derivative of phenol the example below (*6-chloro-m-cresol*) would receive the name *4-chloro-5-methylphenol*. If alternative numbering is possible the lowest numbers are given to the $-\text{OH}$ or $-\text{NH}_2$ group or to the main functional group.

o-Hydroxybenzoic acid
or 2-Hydroxybenzoic acid
(Salicylic acid)

6-Chloro-3-hydroxytoluene
(Chlorocresol)

2-Chloro-5-hydroxy-1 : 3-dimethylbenzene
(Chloroxylenol)

3-Amino-4-hydroxymethylbenzoate
or m-Amino-p-hydroxymethylbenzoate (Orthocaine)

Chlorocresol could be called 6-Chloro-m-cresol or p-Chloro-m-methylphenol, but it is customary to base the name on the hydrocarbon from which the compound is derived, i.e., toluene.

α -Hydroxyphenylacetic acid
(Mandelic acid)

3 : 4-Methylenedioxybenzaldehyde
(Piperonal, Heliotropin)

4-isoPropyl-m-cresol
(Thymol)

3-Acetyl-amino-4-hydroxyphenylarsonic acid (Acetarsol)

Compounds such as *mersalyl* and *tryparsamide* illustrate another method of fixing the position of substituent groups: "N" and "O" in the systematic names indicate that the phenyl-*p*-arsonate substituent is carried by the nitrogen atom in glycineamide and that the acetic acid group is carried by the oxygen atom of salicylamide.

Sodium N-phenylglycineamide-p-arsonate (Tryparsamide)

Sodium salicyl-(γ-hydroxymercuri-β-methoxy) propylamide-O-acetate (Mersalyl)

Where aromatic compounds such as *mandelic acid* possess substituent chains of carbon atoms the carbons of the chain are indicated by the letters of the Greek alphabet starting with the point of attachment, whilst numbers are reserved for the cyclic nucleus. In some cases the cyclic compound may be considered as a cyclic derivative of the aliphatic compound; thus *thyroxine* may be considered as a derivative of alanine.

The interpretation of complicated names may be simplified by the judicious use of brackets, as for thyroxine.

dl-β-[3 : 5-Diiodo-4-(3' : 5'-diiodo-4'-hydroxyphenoxy)phenyl]-α-aminopropionic acid (Thyroxine)

The whole of the grouping within the square brackets is a substituent of the β-carbon atom of α-aminopropionic acid, and the 3' : 5'-diiodo-4'-hydroxyphenoxy group substitutes the hydrogen on the 4-carbon atom in the 3 : 5-diiodophenyl group.

β-Hydroxy-β-(3 : 4-dihydroxyphenyl) ethylmethanamine or *α-(3 : 4-Dihydroxyphenyl)-β-methylaminoethanol* (Adrenaline)

α-Hydroxy-β-methylaminopropylbenzene (Ephedrine)

p-Aminobenzenesulphonamide (Sulphanilamide)

β-Aminopropylbenzene (Amphetamin)

The compound, 1 : 2-diphenylethylene, has been given the name *stilbene*; the two carbons constituting the link are designated α and β .

4 : 4'-Dihydroxy- α : β -diethylstilbene
(Stilboestrol)

On reduction stilbene becomes hexoestrol when the stilbene structure is destroyed and the compound is named as a derivative of hexane.

The difference between the following two compounds should be carefully noted

Diazoaminobenzene

4-Aminoazobenzene

Compounds containing one, two, three, and four *azo* groups are known as *monoazo-*, *bisazo-*, *trisazo-*, and *tetrakisazo-*.

Sodium salt of *α-naphthaleneazo-β-naphthol-3-6-disulphonic acid*

Compounds which contain more than one ring symmetrically placed in arylalkyl union have the numbers of the different rings indicated by one or more dashes.

Chloride of 4-methylamino-4' : 4''-di(dimethylamino)triphenyl carbinol anhydride (Component of methyl violet)

ALICYCLIC COMPOUNDS

Such compounds, though cyclic in structure, exhibit aliphatic properties and the name recognises this fact.

Cyclohexane

Cyclohexene

Cyclohexa-
1 : 4-diene

Cyclohexa-
1 : 3-diene

In the case of cyclohexene there is no need to indicate the position of the double bond by numbers, but when this is necessary the lowest possible numbers are given to the ethylene linkages in the unsaturated nucleus.

1-Methyl-4-isopropyl-
cyclohexane
(*p*-Menthane)

$\Delta^{1,8}$ -*p*-Menthadiene
(Dipentene)

p-Menthane-3-ol
(Menthol)

Many cyclic structures which are the parent structures of natural products are given names reminiscent of a naturally occurring derivative. It should be noted that the convention of retaining numbers for the carbons of the ring and Greek letters for the side chains is not observed.

Cyclohexanol

1-Methylcyclohexan-2-ol

Hexahydroxycyclohexane (Inositol)

Anhydro-p-menthan-1:8-diol
(Eucalyptol or Cineole)p-Menthan-1:8-diol
(Terpin)

The prefix *anhydro* signifies the loss of the elements of water from the 1:8-diol.

In fixing the position of the double bonds in the molecule a single number is sometimes ambiguous: in such cases a second figure is used.

 $\Delta^1(7),2$ -p-Menthadiene
(β -Phellandrene) $\Delta^1,8$ -p-Menthadiene-6-one
(Carvone)

The figure in brackets indicates that the double bond is situated between carbon atoms 1 and 7, since the position of carbon atom 1 makes alternatives possible.

$\Delta^4(8)$ -*p*-Menthen-3-one
(Pulegone)

2:5-Endoisopropylidene-2-methylcyclohexanone
(Camphor)

The systematic name for camphor illustrates the method used for dealing with bridged rings. The term *endo* indicates the bridge, the atoms to which it is attached being specified. The numbering of the camphor nucleus is one that has been accepted by custom. It is based upon the structure of cyclohexanone and not upon the terpene skeleton.

An *alternative method* of nomenclature is in use for both simple and more complex alicyclic compounds. The hydrocarbons are regarded as multiples of CH_2 , *methylene*.

Trimethylene
(Cyclopropane)

Tetramethylene
(Cyclobutane)

Pentamethylene
(Cyclopentane)

In some cases it is convenient to name alicyclic structures as being derived from the corresponding aromatic nucleus.

Hexahydrophthalic acid
(Cyclohexan-1:2-dicarboxylic acid)

Decalhydronaphthalene
(Decalin)

An alicyclic nucleus which is common to the sterols, bile acids, sex hormones, vitamin D and the aglucones of certain cardiac glycosides is numbered as follows:—

The skeleton from which the female sex hormones are derived is called *œstrane*: that of the male hormones *androstane*.

- 3-Hydroxy-17-keto-1 : 3 : 5-*œstratriene* is *œstrone*.
 3 : 16 : 17-Trihydroxy-1 : 3 : 5-*œstratriene* is *œstriol*.
 3 : 17-Dihydroxy-1 : 3 : 5-*œstratriene* is *œstradiol*.

- 3-Hydroxyandrostan-17-one is *Androsterone*.
 17-Hydroxy- Δ^4 -androsten-3-one is *Testosterone*.

Pregnane
or 17-Ethylandrostan-3-one
(Δ^4 -Pregnen-3 : 20-dione is
Progesterone)

Δ^4 -21-Hydroxypregnen-
3 : 20-dione
21-Hydroxypregesterone
(Desoxycorticosterone or
Deoxycorticosterone)

The use of "Deoxy" or "Desoxy" signifies minus one oxygen atom. Corticosterone possesses a hydroxy group at position 11.

HETEROCYCLIC COMPOUNDS

The common hetero-atoms are O, S and N. Numbering generally commences at the hetero-atom to which the smallest number is given, and proceeds in the direction by which any other hetero-atoms receive the smallest numbers possible.

Certain aliphatic compounds possess heterocyclic structures and may be related to the corresponding heterocyclic aromatic nuclei.

Succinic anhydride
(cf. Furan)

γ -Lactone
(cf. Furan)

Furan

Succinimide
(cf. Pyrrole)

γ -Lactam
(cf. Pyrrole)

Pyrrole.

or *Pyridine-β-carboxylic acid*
diethylamide
(Nikethamide)

4-Benzoyloxy-2 : 2 : 6-trimethylpiperidine hydrochloride
(Benzamine hydrochloride)

Azoles. Five-membered heterocyclic structures containing more than one nitrogen atom are termed azoles.

*Pyrazole**Pyrazoline**Pyrazolidine**Pyrazolone*

Reduction products are named in the conventional manner—pyrazole, pyrazoline, pyrazolidine. Keto derivatives change the final *ine* into *one*.

1-Phenyl-2:3-
dimethylpyrazolone-5
(Phenazone)

4-Dimethylamino-1-phenyl-
2:3-dimethylpyrazolone-5
(Amidopyrine)

The figure 5 in the above names fixes the position of the carbonyl group in the molecule.

Sodium salt of 4-(p-sulphobenzeneazo)-1-(p-sulphophenyl)-5-pyrazolone-3-carboxylic acid (Tartrazine)

Glyoxalines. Isomeric structures in which the two nitrogen atoms are differently situated are called *glyoxalines* or sometimes *iminoazoles*.

Glyoxaline

 α -Amino- β -(4-glyoxalyl)propionic acid
(Histidine)4- β -Aminoethylglyoxaline
or β -(4-iminoazoly)ethylamine
(Histamine)

In the above formulæ histidine is treated as a derivative of propionic acid and therefore the α carbon is that to which the carboxylic group is attached. Histamine is treated as an ethylglyoxaline and hence the carbon attached to the ring is designated " α ."

Derivatives of the reduced glyoxaline nucleus are illustrated by the following substances:

Triketotetrahydroglyoxaline
(Oxalylurea or Parabanic acid)2 : 4-Diketotetrahydroglyoxaline
(Hydantoin)5-Phenyl-5-ethyl-2 :
4-diketotetrahydroglyoxaline
or Phenylethylhydantoin
(Nirvanol)Sodium derivative of 5:
5-diphenylhydantoin
(Soluble Phenytoin)

The presence of three nitrogen atoms in a five-membered cyclic structure leads to two tautomeric pairs of compounds. These pairs are distinguished by the names triazoles and osotriazoles.

Tetrazoles contain four nitrogen atoms in the ring.

Tetrazole

Pentamethylenetetrazole
(Leptazol)

The group pentamethylene, $-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_2-$, has two free valencies which substitute the two hydrogens in tetrazole.

Ring systems in which atoms of oxygen or sulphur replace a nitrogen occur and the numbering always commences with the oxygen (or sulphur) atom. The *isoxazoles* correspond to the pyrazoles, the *oxazoles* to the glyoxalines.

Isoxazole

Oxazole

Thiazole

2-(p-aminobenzenesulphonamido)-thiazole
(Sulphathiazole)

Azines are compounds containing six-membered ring systems containing two or more atoms of nitrogen or nitrogen together with oxygen and sulphur, the latter compounds being termed *oxazines* and *thiazines* respectively.

Pyridazine
(Orthodiazine)

Pyrimidine
(Metadiazine)

Pyrazine
(Paradiazine)

Piperazine

The cyclic *ureides* (barbiturates) contain the pyrimidine skeleton.

2 : 4 : 6-*Trihydroxy-pyrimidine* (Barbituric Acid)

5-*Diethyl-2 : 4 : 6-trihydroxypyrimidine*
(Barbitone)

2 : 6-*Dihydroxy-pyrimidine*
(Uracil)

Further examples of derivatives of barbituric acid include the following substances:—

Hexobarbitone = 5- Δ^1 -Cyclohexenyl-5-methyl-N-methyl-barbituric acid.

Phenobarbitone = 5-Phenyl-5-ethylbarbituric acid.

Phemitone = 5-Phenyl-5-ethyl-N-methylbarbituric acid.

Piperazines. The cyclic anhydrides formed by the loss of two molecules of water from two molecules of α -amino acids are derivatives of piperazine.

6-Methoxy-8-[(ω -diethylamino- α -methylbutyl)]aminoquinoline
or *N-(ω -diethylamino- α -methylbutyl)-6-methoxyquinoline*
Pamaquin is the salt of this base with the acid illustrated below.

2:2'-Dihydroxy-1:1'-dinaphthylmethane-3:3'-dicarboxylic acid

When a cyclic system is a substituent in a condensed nucleus its positions are indicated by $1'$, $2'$, etc.

2-Phenylquinoline-4-carboxylic acid (Cinchophen)

Ethyl 6-methyl-2-phenyl-quinoline-4-carboxylate
(Neocinchophen)

This is also illustrated by quercetin (3 : 5 : 7 : 3' : 4'-Pentahydroxyflavone) and catechin.

Quercetin

Catechin

Acridines. Care should be taken in interpreting the names of derivatives of acridine, since no agreement has been reached and different countries use different systems of numbering. All publications referring to acridine derivatives—and indeed derivatives of other cyclic systems—should contain a key plan of the system adopted. The system adopted here is that which is current in Great Britain.

2 : 8-Diaminoacridine
(Proflavine)

2 : 8-Diamino-10-methylacridinium

aminoacridine
(Chrysianiline)

2-Chloro-5-(ω -diethylamino- α -methyl-
butyl)amino-7-methoxyacridine
(Mepacrine)

The "5" position in the acridine nucleus is sometimes designated as "meso," whilst the dyes derived from 5-phenylacridine are technically known as "phosphines."

mesoChloroacridine

Symmetrical Ureas

Symmetrical urea of the sodium salt of m-benzoyl-m-amino-p-methylbenzoyl-1-aminonaphthalene-4 : 6 : 8-trisulphonic acid
(Suramin)

Compounds of this nature are symmetrical derivatives of urea and are known as symmetrical ureas. The official systematic name would be improved if the two *m*s were distinguished as *m'* and *m* respectively to show that they referred to different nuclei. The name is not a good one, but substances of this complexity present serious difficulties in nomenclature. A more accurate description would be: The sodium salt of sym-bis-m-[o'-methyl-m'-(4 : 6 : 8-trisulpho-1-naphthyl-carbonamido) phenyl] carbonamidophenylurea. The words outside the brackets indicate that the substance is a symmetrical di-derivative of diphenylurea substituted in the *m*-position by -CO-NH which carries on the N atom a phenyl substituent itself substituted by an o'-methyl and a m'(4 : 6 : 8-trisulpho-1-naphthylcarbonamido) group.

DERIVATIVES OF ARSENIC, ANTIMONY OR PHOSPHORUS

A meeting of the International Committee on Nomenclature held at Lucerne in 1936 reached agreement with regard to compounds of arsenic, antimony and phosphorus.

Derivatives of arsine, AsH_3 , are named like amines. Thus— CH_3AsH_2 , *Methylarsine*; $(\text{CH}_3)_2\text{AsCl}$, *Chlorodimethylarsine*; $(\text{CH}_3)_3\text{AsO}$, *Trimethylarsine oxide*; $\text{H}_2\text{As}-\text{CH}_2-\text{CH}_2-\text{AsH}_2$, 1 : 2-*Diarsinoethane*; $(\text{C}_2\text{H}_5)_4\text{AsOH}$, *Tetraethylarsonium hydroxide*.

$\text{RAs}(=\text{O})(\text{OH})$ and $\text{RAs}(=\text{O})(\text{OH})_2$ are named arsenic acids. $\text{RAs}(=\text{O})(\text{OH})_2$ are named arsonic acids. The corresponding prefixes are *arsenico* [$=\text{As}(=\text{O})(\text{OH})$], and *arsono* [$-\text{As}(=\text{O})(\text{OH})_2$]. Thus $(\text{CH}_3)_2\text{AsO}_2\text{H}$ is *Dimethylarsenic acid*; and $\text{C}_6\text{H}_5\text{As}(=\text{O})(\text{OH})_2$ is *Benzenearsonic acid*.

The system is applicable to P and Sb compounds, the syllable “ars” being replaced by “phosph” or “stib” respectively. The following table gives the prefixes and suffixes.

| Radical | Prefix | Suffix |
|---|---------------------------|-------------------|
| $-\text{AsH}_2$ | <i>arsino</i> | <i>arsine</i> |
| $-\text{AsO}$ | <i>arsenoso</i> | |
| $-\text{AsO}_2$ | <i>arso</i> | |
| $=\text{As}(=\text{O})(\text{OH})$.. | <i>arsenico</i> | <i>arsenic</i> |
| $-\text{As}(=\text{O})(\text{OH})_2$.. | <i>arsono</i> | <i>arsonic</i> |
| $-\text{As}=\text{As}-$ | <i>arseno</i> | |
| $-\text{PH}_2$ | <i>phosphino</i> | |
| $-\text{PO}$ | <i>phospho</i> | |
| $=\text{P}(=\text{O})(\text{OH})$.. | <i>phosphinico</i> | <i>phosphinic</i> |
| $-\text{P}(=\text{O})(\text{OH})_2$.. | <i>phosphono</i> | <i>phosphonic</i> |
| $-\text{P}=\text{P}-$ | <i>phosphoso</i> | |
| $-\text{P}=\text{N}-$ | <i>phosphazo</i> | |
| $-\text{P}=\text{As}-$ | <i>phospharseno</i> | |
| $-\text{SbH}_2$ | <i>stibino</i> | <i>stibine</i> |
| $-\text{SbO}$ | <i>stiboso</i> | |
| $-\text{SbO}_2$ | <i>stibo</i> | |
| $=\text{Sb}(=\text{O})(\text{OH})$.. | <i>stibinico</i> | <i>stibinic</i> |
| $-\text{Sb}(=\text{O})(\text{OH})_2$.. | <i>stibono</i> | <i>stibonic</i> |
| $-\text{Sb}=\text{Sb}-$ | <i>antimono</i> | |
| $-\text{Sb}=\text{As}-$ | <i>stibarsino</i> | |

Compounds similarly related to BiH_3 , *bismuthine*, are treated in the same manner.

3 : 3'-Diamino-4 : 4'-dihydroxy-arsenobenzene
(The dihydrochloride is Salvarsan)

3 : 3'-Diamino-4 : 4'-dihydroxy-arsenobenzene-N-methylene-
sulphoxylate
(Neoarsphenamine)

3 : 3'-Diamino-4 : 4'-dihydroxy-arsenobenzene-N-N-dimethylene
bisulphite
(Sulpharsphenamine)

Sodium-antimony-bispyrocatechol-3 : 5-sodium disulphonate
(Stibophen)

STEREoisomeric Compounds

Optically active compounds are referred to *d*-glucose as the standard. Some confusion exists in the nomenclature since the letters *d* and *l* are used to indicate the relationship of the compound to that standard and have no reference to the direction of rotation. The dextro- or lævo-rotation of the substance is indicated by the symbol + or - : thus *d*(-) is used to indicate that a compound has dextro- configuration but is lævorotatory, and similarly *l*(+) means the exact opposite. At the same time *d* and *l* are used to show the direction of rotation. In order to avoid this confusion it is advisable to use the capital letters D and L for configurational relationship. Thus, lævorotatory *mandelic acid* which has dextro-configuration would then be called D(-) or D(*l*) mandelic acid. The letter *r* indicates the racemic compound of two antimerides, *dl* the optically inactive mixture and *i* the *meso* or internally compensated, non-resolvable form.

Pairs of diastereoisomerides are often differentiated by the term *pseudo* (ψ) as instanced by the following alkaloids of ephedra.

l-Ephedrine

d-Ephedrine

(l- and d- α -hydroxy- β -methylaminopropylbenzene)

l-pseudoEphedrine

d-pseudoEphedrine

(l- ψ - and d- ψ - α -hydroxy- β -methylaminopropylbenzene)

Geometric isomers of the ethylene type are defined by the terms *cis* and *trans*, whilst for the carbon nitrogen geometric isomerides the terms *syn* and *anti* are used.

The benzildioximes illustrate the use of a third term, namely *amphi*.

syn-Benzildioxime

anti-Benzildioxime

amphi-Benzildioxime

Allo is also used to signify the less common of the two geometric isomers but the term has historical significance only.

Use of Italics. Italics are used for a prefix which indicates an isomer. Thus, *o*, *m*, *p*, *cis*, *syn*, *anti*, *trans*, *pseudo*, *meso*, etc., should all be italicised, but not the terms "nor" and "homo." "Nor" should be used to indicate the next lower homologue, and "homo," the next higher: the compounds indicated are not isomeric with the parent of the name.

General Conclusions

It will be noticed that alternative names are often possible, but every name used should be, so far as possible, free from ambiguity. The general method of obtaining the name from the formula should be as follows: one of the substituents is chosen as the principal function—carboxyl, if present, is the invariable choice—and is given the lowest possible number; next the longest chain carrying that function and the greatest number of substituents provides the root name. The reverse procedure, deducing the formula from the name, consists of looking along the name for the syllable not preceded by a number to obtain the root and at the termination for the principal function.

From July 1st, 1942, the composition of all "substances recommended as medicines" must be disclosed. A preparation which is official in the *B.P.* or *B.P.C.* may be sold under its official title and the constituents need not be enumerated. The constituents of all other preparations must be disclosed. If the constituents are official in the *B.P.* or *B.P.C.*, an official name, synonym or abbreviation must be used. If such be not the case "the accepted scientific name, or other name descriptive of the true nature of the substance, constituent or ingredient" may be used.

The "accepted scientific name" may be interpreted as being a non-ambiguous, systematic, chemical name: the name should disclose to a competent chemist the chemical structure or identity of the ingredient. This new enactment focuses attention on the

principles of nomenclature. Previously similar provisions applied only to substances mentioned in the Poisons List.

Systematic names are often cumbersome but should always be used where it is desirable to indicate the structure of a compound. "Decalin" and "tetralin" give no indication of the composition of the compounds; memory must be invoked to associate the name with the structure. This in itself is a sufficient plea for systematic nomenclature. The study of organic chemistry would be almost impossible if the student had to learn individual names for some hundreds of thousands of compounds. Systematic nomenclature—international, if possible—is obviously the rational alternative to what, otherwise, would be a state of chaos.

CHEMOTHERAPY

The Relation between Chemical Constitution and Therapeutic Effect

On the continent the term chemotherapy is restricted to the study of substances used in combating an invading organism. It is more reasonable to widen its scope to include the investigation of all substances, the therapeutic effect of which is related to chemical structure. For the purpose of this summary the latter interpretation will be used.

The middle of the nineteenth century was a period of great activity in the determination of the constitution of the active principles of many vegetable drugs. One of the most important characters of such substances is their physiological action and, naturally, attempts were made to relate such activity to the chemical constitution of the molecule. Thus the science of chemotherapy came into being. Probably the first successful generalisation in this field was that of Crum Brown and Fraser (*Proc. roy. Soc. Edinb.*, 1867, 560). They showed that various alkaloids, possessing the most diverse physiological actions, on combination with alkyl halides to form quaternary ammonium derivatives,

where $\text{R}_1\text{R}_2\text{R}_3$ are organic radicles of any complexity and RX stands for alkyl halide, methyl or ethyl iodide, etc., yield substances in almost every case possessing the property of paralysing the motor nerve-endings in the same way as curare. One can obtain, therefore, by methylation of all tertiary bases, quaternary ammonium compounds which are much more poisonous than the original bases. Curare itself contains the tertiary base curine which is not very poisonous, as well as the far more poisonous

ammonium base curarine. Curine on methylation yields curarine which is 226 times as toxic as the original substance. This early success stimulated the hope that it would be possible to correlate physiological action with chemical constitution.

Later, the use of dyestuffs for the selective staining of bacteria suggested the possibility of preparing dyes which might kill or inhibit the growth of pathogenic organisms.

Theories of Physiological Action. One of the earliest general hypotheses was that of Loew (*Natürliche System der Giftwirkung*, Munich, 1893) who held that all substances which react with aldehydes or amines, either by addition or substitution, must possess physiological activity. According to him the greater the reactivity the greater the physiological result, e.g., phenylhydrazine and hydroxylamine are very reactive to ketone and aldehyde groups—hence poisonous both to plants and animals. Aniline is less reactive to aldehydes than phenylhydrazine and is less poisonous than the latter. If the chemical properties of a substance are made more labile by a change in the character of the molecule, then it becomes more toxic, and vice versa, e.g., if the hydrogen of the NH group in many alkaloids be replaced by a methyl group the toxicity is diminished since the substance reacts less readily with aldehydes. Similarly piperidine is more toxic than pyridine, and tetrahydroquinoline is far more toxic than quinoline by reason of the fact that the reduced compounds which contain secondary nitrogen in place of tertiary have a greater reactivity with protoplasm. Compare also pyrogallol (trihydroxybenzene) which is more poisonous than dihydroxybenzene (catechol) and phenol. The toxicity of phenols, is, in the light of this theory, attributed to their reactivity, especially with aldehydes. Salicylic acid (introduction of COOH) is less reactive with aldehydes than phenol, hence less toxic. Loew's theory is restricted to those substances which react with aldehyde and amino-groups and offers no explanation for selective action. As every tissue contains such groups, all drugs should possess a general activity.

Ehrlich (*Proc. roy. Soc.*, 1900, 424; *Studies on Immunity*, 1906, pp. 404-442) suggested a parallel between the action of a drug and the process of dyeing. Witts' theory of dyeing postulates the presence of a chromophore and a salt-forming group in the dye and, by analogy, the drug must contain a "pharmacophore" and an anchoring group. Thus, by changing the type of anchoring group, the seat of action may be moved and the physiological property of the drug altered. In morphine, the anchoring group may be one, or both, of the hydroxyls and the protection of these by the entrance of an organic radicle, methyl, ethyl, or acetyl, causes the hypnotic power to be reduced whilst action on the respiratory centres (produced by morphine to a slight extent) is much increased, e.g., codeine and diamorphine. Again, benzoyllecgonine is twenty times less toxic than its methyl ester (cocaine). It is only necessary for benzoyllecgonine to be esterified—the alcohol used is comparatively unimportant—for the typical action of cocaine to appear, and thus it may be that the anchoring group responsible for the local anæsthetic action does not become operative until the carboxyl is masked.

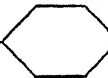

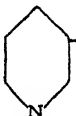

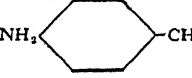

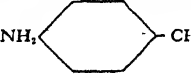

Although these views have not been borne out entirely by subsequent work, they have proved very stimulating to research and have therefore served a useful purpose. One of the main difficulties with such a theory is that it does not explain the varying activity of compounds containing the same groupings differing only in their orientation.

It has been suggested that such difficulties may be met by substituting a theory of indirect action. Thus, bactericides may function by stimulating the formation of antibodies in the host. If this were true the substances should be able to promote immunisation, but as yet no evidence in support has been obtained.

Voegtlin (*Physiol. Rev.*, 1925, 63) has suggested that the activity of the arsenicals is due to their reduction to arsine oxide derivatives which then react with the reduced glutathione present in the tissues. But again the selective action of isomers is not explained.

Recently a theory of indirect action has come into prominence which appears to be based, in certain cases, upon experimental results. According to this theory a drug may exert its activity by interference with an essential enzyme or with an essential metabolite. Thus Loew and Navrátil attribute the action of

physostigmine on the heart to inhibition of choline esterase. The Stedmans found that certain simple urethanes which inhibited many of the properties of physostigmine also showed this inhibitory power. Gaddum (*Pharm. J.*, 1938, 271) suggests that some of the effects of ephedrine are due to its inhibition of an amine oxidase which destroys adrenaline and other amines by removing nitrogen. Woods (*Brit. J. exp. Path.*, 1940, 21, 74) found that *p*-aminobenzoic acid antagonised the bacteriostatic action of sulphanilamide *in vitro*, and Selbie (*ibid.*, 1940, 21, 90) obtained the same result *in vivo*. Fildes (*Lancet*, i/1940, 956) suggested that the activity of sulphanilamide is due to its competition for *p*-aminobenzoic acid which he regarded as a component of an enzyme which was an essential metabolite for those organisms affected by sulphanilamide. The antagonism of *p*-aminobenzoic acid and sulphanilamide has been confirmed by several other workers. McIlwain (*Brit. J. exp. Path.*, 1940, 21, 136; 1941, 22, 148) has found that nicotinic acid and pyridine- β -sulphonic acid are mutually antagonistic and this lends support to the general theory. Barnett and Robinson (*Biochem. J.*, 1942, 36, 364) have shown that pantoyletaurine inhibits pantothenic acid, a constituent of the vitamin B₅ complex which is known to be an essential metabolite for the growth of a number of organisms. The relationship of these growth factors and the inhibitor is shown in the following table

| Growth Stimulator | Corresponding Inhibitor |
|---|---|
| 1.  <i>p</i> -Aminobenzoic acid |  <i>p</i> -Aminobenzenesulphonic acid |
| 2.  Nicotinic acid |  Pyridine- β -sulphonic acid |
| 3.  <i>p</i> -Aminophenylacetic acid |  <i>p</i> -Aminophenylmethanesulphonic acid |
| 4. $\text{CH}_2\text{OH}\cdot\text{C}(\text{CH}_3)_2\cdot\text{CHOH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{COOH}$ Pantothenic acid | $\text{CH}_2\text{OH}\cdot\text{C}(\text{CH}_3)_2\cdot\text{CHOH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{SO}_3\text{OH}$ Pantoyltaurine |

If this theory is found to be universally applicable another avenue of approach to chemotherapeutic problems is available. An investigation concerning the essential factors for growth of an organism might lead to the production of an inhibitor for one or more of them.

Effect of Stereoisomerism. Fischer's famous "lock and key" simile has been invoked to explain the well-known differences in compounds related stereochemically. Sometimes the character, as well as the potency, of the reaction is different, e.g. *l*-hyoscyamine and *d*-hyoscyamine. Difference in potency is best illustrated by *l*-adrenaline which is many times more active than

its enantiomorph. Again *cis* and *trans* dichlorethylenes show considerable differences in physiological behaviour. The characteristic action of the quaternary ammonium compounds does not appear to be dependent upon the presence of nitrogen as it is exhibited by the S, P, and As analogues. Such substances have one common characteristic—the tri-dimensional form of their molecules.

Physical Factors. Many chemically inert substances possess hypnotic properties. There appear to be few chemical relationships between paraldehyde, chloral hydrate, sulphonal, urethanes, and ureides, and hence Overton and Meyer independently suggested that similar physical properties were responsible for the physiological action of bodies belonging to such different common chemical types. They proved that it was possible to obtain approximately the relative potencies of hypnotics by studying the partition coefficients between olive oil and water. Meyer compared partition coefficients with the fraction of the molecular weight required to produce immobility, and obtained the following results:—

| Substance | Partition Coefficient (olive oil : water) | Molecular amount to produce immobility |
|--------------------|--|---|
| Methylsulphonal .. | 4.4 | 0.0013 |
| Tetronal | 4.0 | 0.0018 |
| Sulphonal | 1.1 | 0.006 |
| Bromal hydrate .. | 0.7 | 0.006 |
| Chloral hydrate .. | 0.2 | 0.002 |
| Ethyl urethane .. | 0.14 | 0.04 |
| Alcohol | 0.03 | 0.5 |

It will be seen that the two methods classify the substances in approximately the same order.

Such a theory accords with the fact that the nerves are surrounded by lipid matter which would protect the nerve fibres from substances insoluble in lipoids. On the other hand, the theory does not explain the action of the drug on the nerve fibre itself or the specificity of the action of certain identities.

The physical properties of a drug and its chemical stability may determine whether the substance can reach the required seat of action without suffering decomposition or general absorption, but it is unlikely that such properties offer a complete explanation for the physiological activity.

Metabolic Reactions. The ultimate fate of the drug in the body is bound to have an effect upon its activity. In general, the changes which occur lead to the production of a less toxic compound by way of hydrolysis, oxidation, or reduction, sometimes followed by the combination of the product with sulphuric, glycuronic, or aminoacetic acid. Hydrolysis takes place in the alimentary tract. The saliva usually has little action; salts of organic acids are generally decomposed into the free acid and a chloride of the base, but esters and similar bodies are in the majority of cases undecomposed by the gastric contents. In the small intestine, however, the drug encounters the pancreatic enzyme, trypsin, and an alkaline medium. Trypsin has marked hydrolysing action on esters, anilides, and similar bodies,—here, after saponification, the components of the drug exert their specific action. Oxidation and reduction occur in the tissues and in the blood. Aliphatic substances are often completely oxidised to carbon dioxide, water, and urea although the methyl group appears to offer considerable resistance. For instance, acetone is oxidised with difficulty, diethylketone easily, whilst methylethylketone occupies an intermediate position. Primary and secondary alcohols are easily decomposed, whilst tertiary alcohols and chloro-derivatives are comparatively resistant.

Aromatic substances are more stable and the nucleus usually remains intact: side chains are converted into carboxyl groups (toluene gives benzoic acid) whilst other substances are transformed into the *para*-hydroxyl derivative. Aniline yields *p*-aminophenol, and this fact accounts for the introduction of derivatives of this compound into medicine, phenacetin being a well-established example. An interesting action of demethylation occurs in the case of xanthine, theobromine and caffeine, the first being without action on the heart muscle, the second acting slightly and the third showing more marked toxic action.

It was found that the products of metabolism after giving caffeine and theobromine contain xanthine bases poorer in methyl groups than the substances given. In man, caffeine is reduced to theophylline,—this shows that there is a splitting off of methyl groups, which groups appear to be responsible for action on the heart, i.e., there is a relationship between physiological action and the changes undergone by the substance in the organism. Reduction occurs much more rarely—quinone forms hydroquinone and certain substituted nitro-compounds are reduced to the corresponding amino-compounds although nitrobenzene is not converted into aniline.

It has been mentioned that products of these reactions are often eliminated in combination with certain acids.

Phenols form the potassium sulphuric esters unless the phenol is relatively non-toxic when it is eliminated unchanged. Methyl salicylate combines with sulphuric acid, but salicylic acid, owing to the presence of the carboxyl group, forms the ester with aminoacetic acid. Aliphatic compounds eliminated with glycuronic acid, $\text{CHO}(\text{CHOH})\cdot\text{COOH}$, probably react with glucose to form a glucoside which is then oxidised to the glycuronic acid derivative. Aromatic compounds form an additive compound with the aldehyde group of this acid. The condensation with aminoacetic acid can be illustrated by the formation of hippuric acid:—

Thus, benzoic acid, derivatives of benzoic acid, and similar substances formed by oxidation are eliminated as hippuric acid and its derivatives.

The possibilities of such reactions make it necessary to know whether the physiological effect produced by a compound is in fact due to that compound or to an artefact formed after absorption. It was once thought that the action of chloral hydrate was due to its decomposition into chloroform in the body, but it was later determined that the hypnotic action was due to the corresponding alcohol produced by the reduction of chloral. An interesting sequel was the introduction into medicine as a basal narcotic of a solution of tribromoethyl alcohol in amylene hydrate (Bromethol).

From the above survey it is apparent that no one theory explains satisfactorily physiological action, and few generalisations can be made. In fact the original finding of Crum Brown concerning quaternary ammonium compounds still remains almost unique. Other fairly well-established generalisations may include: (a) benzoylation of amino-alcohols always gives rise to local anaesthetics; sometimes the use of the *p*-aminobenzoic derivative is preferable as in procaine; (b) the β -position in arylaliphatic amines (e.g., β -phenylethylamine derivatives) appears to be of importance in sympathomimetic compounds; (c) the ethyl group is important in certain classes of hypnotics; (d) the introduction of strongly acidic groups such as the carboxyl and sulphonic acid groups, often reduces toxicity and activity. Acylation of amines produces the same effect.

In addition to these few generalisations, a vast amount of information has been obtained, but the findings are applicable only to the series concerned. However, the following summary of the effects of common groupings may serve to illustrate the type of knowledge available.

Inorganic Substances. Blake, in 1839, stated that any action was due to the electro-positive radicle, acid groupings being inert. In 1881 it was stated that activity increased with increase of atomic weight amongst isomorphous substances—e.g., Li, Na, Rb, Cs, Ag and Tl; Mg, Mn, Co, Ni, Cu, Zn, Cd; Ca, Sr, Ba. Potassium and ammonium provide exceptions but these are also exceptions to Mitscherlich's law of isomorphous substances possessing similar spectra.

Amongst the electro-negative elements there appears to be no relation between activity and atomic weight. The effect appears to be due to the ions and hence ionisation plays an important part: mercuric cyanide is soluble but little ionised and is much less poisonous than mercuric chloride. Phosphonium, arsonium and stibonium bases exhibit no reactions of P, As, or Sb but resemble the corresponding nitrogen compounds.

Organic Substances. Aliphatic compounds mainly produce hypnotics, and aromatic compounds antipyretics.

Hydrocarbons. Aliphatic hydrocarbons which exhibit volatility and solubility are narcotic, the activity reaching a maximum at C_8 and C_7 . Activity is increased on the introduction of a

double bond. Amongst aromatic hydrocarbons benzene compounds show a paralysing action on the motor nerves and a further effect on the brain and spinal cord. Naphthalene is less toxic than benzene.

Alkyl Groups. In homologous series of compounds produced by varying alkyl radicles, peaks of activity occur—not always at the same point. The ethyl group appears to be particularly effective in hypnotics as illustrated by the sulphones. More generally the peak occurs with the butyl or amyl member.

In derivatives of barbituric acid the two substituent groups on the 5-carbon atom should together contain not less than 4 or more than 8 carbon atoms, and at least one of the groups should be aliphatic. Outside these limits derivatives are either too toxic or too inactive for use.

Replacement of hydrogen of the nucleus by methyl produces an increase in the effects, *cf.* also the methylation of xanthine (*antea*). Replacement of the hydrogen of a hydroxyl group often reduces activity, *cf.*, catechol, $C_6H_4(OH)_2(1:2)$, guaiacol, $C_6H_4OH \cdot OCH_3$, and veratrole, $C_6H_4(OCH_3)_2$. Again *ortho*-methoxybenzoic acid, $C_6H_4OCH_3 \cdot COOH$, and anisic acid, $C_6H_4OCH_3 \cdot COOH(1:4)$, are less active than salicylic acid, $C_6H_4OH \cdot COOH$, but this is not invariably true—resorcin, $C_6H_4(OH)_2(1:3)$, is far less poisonous than dimethyl-resorcin, $C_6H_4(OCH_3)_2(1:3)$.

Alkylation of amines reduces toxicity. Some interesting cases of specificity occur: for instance, certain dyes containing the diethylamino group stain nerve fibres whereas the corresponding methyl derivatives are inactive (Ehrlich and Michaelis); *p*-phenetolcarbamide, $C_2H_5O \cdot C_6H_4 \cdot NH \cdot CO \cdot NH_2$ (dulcin), is intensely sweet whilst the methyl analogue is tasteless. No general rule can be postulated concerning the introduction of the phenyl group.

Hydroxyl Groups. Depend upon the function which they perform.

Alcohols. Narcotic action reaches a maximum at C_7 , and activity increases with the branching of the chain: secondary are more active than primary, tertiary than secondary; e.g., amylene hydrate. Introduction of further hydroxyls reduces activity, the effect being roughly proportional to the number present. Solubility in water increases as does the property of sweetness, *viz.*, monohydric alcohols, glycols, glycerol, mannitol, etc.

Phenols. Introduction of $-OH$ into the aromatic nucleus increases activity and often promotes antiseptic qualities. Amongst the homologues of phenol, increase in molecular weight is accompanied by increased activity and reduced toxicity. Polyhydroxyphenols are still more active and the meta compounds are least active: phloroglucinol is the least active of all the di- and tri-hydroxybenzenes. Alkyl resorcinols are stronger bactericides than resorcinol, the peak being reached with 4-hexylresorcinol.

Halogens. In aliphatic bodies there is increase in narcotic power, but there is also an increase in depressant action on the heart and blood vessels. The narcotic power and toxicity of chlorine compounds is well seen in the case of the chlorhydrins,—narcotics and vasodilators derived from glycerin which is inert, tri-chlorhydrin being most active and the mono-compound least. Note that in the case of the tri- and mono-chloracetic acids the toxicity is reversed. Halogen introduced in the benzene nucleus causes little alteration in properties. Organic iodine compounds differ from those of chlorine and bromine in having greater antiseptic and toxic properties and diminished hypnotic effects, *cf.*, CHCl_3 , CHBr_3 , CHI_3 .

Although the entrance of halogens increases the narcotic action of a drug, the molecule acts as a whole, neither chlorine nor bromine being set free in the tissues. Examples: chloral hydrate, chlorbutol.—J. Grier, *Brit. colon. Drugg.*, i/1913, 282.

Aldehydes. Formaldehyde is very reactive chemically and physiologically. It is a strong irritant to the mucous membrane and coagulates proteins. Acetaldehyde produces excitation and then anæsthesia. Paraldehyde is stronger in action than the latter. By entry of OH into the aldehyde molecule and by condensation of these bodies to form aldols, reactivity is lowered, as also physiological power—the sugars are practically inert. The aromatic aldehydes are of low toxicity.

Ketones. Similar to alcohols—narcotic. Hypnotic action is seen in the mixed ketones, e.g., acetophenone, $\text{C}_6\text{H}_5\cdot\text{CO}\cdot\text{CH}_3$.

Acid Groups. The introduction of such groupings usually increases considerably the solubility and therefore the “dispersibility” of a compound. Hence they cause generally a decrease in activity or total suppression, e.g., substances containing an OH group, on combining with sulphuric acid, lose their toxicity—phenol is toxic but phenylsulphuric acid is harmless, *cf.* also morphine, $\text{C}_{17}\text{H}_{17}\text{NO}(\text{OH})_2$, and morphine-sulphuric acid, $\text{C}_{17}\text{H}_{17}\text{NO}(\text{OH})\cdot\text{O}\cdot\text{SO}_2\cdot\text{OH}$ —this latter is practically inert. The sulphonic acids of various drugs are in nearly every case of little use; the introduction of carboxyl (COOH) is almost analogous. For example, COOH reduces the toxicity of benzene, which can be taken in doses of 8 g. per day in comparison with a dose of 12 g. to 16 g. of benzoic acid. Methylamine, NH_2CH_3 , is toxic; glycine, $\text{NH}_2\text{CH}_2\cdot\text{COOH}$, is harmless. If the carbomethoxy group in cocaine be hydrolysed there is a total loss of activity which is regained on esterification.

Acylation of amino groups—i.e. the introduction of an acid residue—has a similar effect on toxicity. The base is liberated slowly by hydrolysis and thus the action is retarded and the concentration of the base remains below the toxic limit. The acetyl group is most generally used but the lactyl, benzoyl and salicyl are not uncommon. Practically all synthetic antipyretic and analgesic drugs contain the acetyl radicle. Not only so but it occurs in such naturally occurring pain-relieving drug-principles as aconitine and colchicine.

Nitro and Nitroso Groups. Replacement of the hydrogen of the hydroxyl-group by the nitro- and nitroso- groups yields the nitrates and nitrites respectively. Both these classes of substances are vasodilators. Peak of activity is obtained at C_5 (amyl nitrite), the nitrites of secondary and tertiary alcohols being stronger than those of primary. Glyceryl trinitrate and erythritol tetranitrate are examples of nitrates used for the same purpose.

Introduction of the nitro group into aromatic compounds invariably increases toxicity and is not accompanied by any action of dilatation.

The CN Radicle. Isocyanides (isonitriles) cause paralysis of the respiratory centre and the cyanides (nitriles) produce coma. Neither, however, are as poisonous as HCN. The lower members in the fatty series, CH_3CN and C_2H_5CN , are less poisonous than the higher—cyanacetic acid, $CNCH_2\cdot COOH$, is practically non-toxic. Cyanogen chloride, $CNCl$, on the other hand, is very toxic as it readily yields HCN.

Basic Nitrogen Groups. These can produce in either series important changes. The introduction of alkyl groupings into such bodies increases basicity and reduces toxicity and as before gives hypnotic effect, e.g., carbamic acid, NH_2COOH (poisonous), gives urethane (ethyl carbamate)—more stable and hypnotic. Hydrazine, NH_2-NH_2 , is far more toxic than NH_3 , but the tetra- and penta-methylenediamines are non-toxic.

The entry of the amino group into the benzene nucleus forms the groundwork of a large number of antipyretics and analgesics. The aromatic amines are less basic than ammonia. Aniline, like ammonia, produces convulsions, but like benzene it also causes paralysis of muscles and nerves, and if one of the hydrogen atoms of the NH_2 group be replaced by alkyl the convulsions disappear but the paralyzing action remains. If a hydrogen atom in the nucleus be replaced by a single atom, e.g., Br, the convulsive effect is retained, and if it is replaced by an alkyl group the effect is increased, but if a complex group, especially an acid group, e.g., SO_3H , enters the nucleus, the effect is lost, e.g., in aminobenzene-sulphonic acid, $C_6H_4\cdot NH_2\cdot SO_3H$. All these derivatives, e.g., aniline, have a toxic action on the blood, forming methæmoglobin. As a rule, aromatic derivatives of NH_3 lower body temperature.

Alkaloids. No general clue to physiological effects is possible since in most cases the whole molecule appears to be essential. Most alkaloids possess valuable and potent physiological actions often accompanied by dangerous and unwanted side effects, as witness the habit-forming characteristics of morphine and cocaine. For this reason the efforts to synthesise compounds retaining the physiological effect of many alkaloids, but without the unwanted reactions, have not only contributed new and important drugs but have been instrumental in widening the boundaries of knowledge of chemotherapy. The following summary contains many of the recent introductions of synthetic

"chemical improvements" of certain alkaloids which have been produced by work along these lines.

(See also J. A. Aeschlimann, *J. Soc. chem. Ind., Lond.*, 1935, 136T.)

Quinine. This alkaloid has both antipyretic and antimalarial activity. Consideration of the activity of the various cinchona alkaloids as antimalarials indicates that neither the methoxy group nor the double bond present in quinine is essential. On the other hand the alteration of the secondary alcoholic group in quinine by oxidation or reduction destroys the activity. The synthetic antimalarials that have been introduced bear little relationship to quinine in structure and hence it appears that there are two essentials necessary for antimalarial activity: the presence of a quinoline nucleus and a centre of strong basicity.

The first synthetic antimalarial was pamaquin (I), introduced in 1927 under the name of Plasmoguin. This substance acts at a different stage in the life history of the parasite from quinine and was obtained as a result of studies on the molecule of methylene blue which was known to possess some antimalarial activity. Mepacrine (II), introduced under the name of Atebrin, was the result of the introduction of the basic side chain of pamaquin into other nuclei. Mepacrine acts similarly to quinine.

A large number of compounds similar to the above types have been produced in recent years (Pyman, *Chem. Ind. Rev.*, 1930, 758; Kernack, *J. chem. Soc.*, 1931, 3089; Mike and Robinson, *J. chem. Soc.*, 1933, 1467; Madison and Strukow, *Arch. Pharm., Berl.*, 1933, 271, 359; 1934, 272, 74) from which it appears that the 6-hydroxy-derivative instead of the alkoxy-derivatives are worthy of attention.

Little success has been achieved with synthetic antimalarials closely related to the quinine molecule. The first substance of

this nature possessing some activity, obtained by Ainley and King (*Proc. roy. Soc.*, 1938, 125, 60), was 4-(6-methoxyquinolyl)- α -piperidylcarbinol (III). It had about the same M.T.D. as quinine but was about one-half as effective in terms of the therapeutic index.

It is remarkable that N-alkyl derivatives of (III) possess no activity in spite of the fact that both nitrogens in quinine are tertiary.

Ergot Alkaloids. The constitution of the ergot alkaloids still remains unknown, and the problem becomes ever wider by the isolation of new alkaloids. However, Fourné and collaborators have found that the benzodioxan derivative (IV) possesses many of the characteristic actions of the ergot alkaloids.

None as yet has been prepared containing the pyrrolidine ring, but β -eucaine (the lactate of the base being known as benzamine lactate) reflects the piperidine nucleus. Many have been derived by imitating the amino-alcohol structure represented in bold type in the above formula and sufficient data is available to say that all amino-alcohols, if esterified with a certain range of acids, yield local anæsthetics. Compare the following:—

Structure in cocaine,

Tutocaine base,

Butyn base,

Novocain base (Procaine),

Stovaine base (Amylocaine),

The above examples illustrate the fact that the number of carbons between the amino and alcoholic groups need not be the same as in cocaine: Tutocaine most closely follows the cocaine plan but procaine and amylocaine depart from it. The acid used for esterification of the amino-alcohol is in many instances *p*-aminobenzoic acid as this appears to be more effective than benzoic acid. The simple esters of aminobenzoic acids and their derivatives, such as benzocaine (ethyl *p*-aminobenzoate), orthocaine (methylester of *p*-hydroxy-*m*-aminobenzoic acid) and propæsin (propyl *p*-aminobenzoate) indicate that the anæsthetic activity is retained in some measure by comparatively simple molecules.

General Anæsthetics. Since the introduction of ether by Long in 1842, closely followed by chloroform and nitrous oxide, few additional substances have been introduced as general anæsthetics. Practically the only other substance of importance is ethylene, which covers the same field as nitrous oxide.

Recently two new anæsthetics have been introduced, a preparation of vinyl ether (Vinesthene) and cyclopropane. Insufficient evidence is available concerning the latter but the former appears to induce anæsthesia very rapidly, allows quick recovery and

produces complete relaxation of the muscles. It has also found use in obstetrics. Another approach to this problem is illustrated by the introduction of bromethol (tribromoethyl alcohol dissolved in amylene hydrate) and the use of some of the newer barbiturates.

Barbiturates. 5 : 5'-Dialkyl or aryl derivatives of barbituric acid (malonylurea) form potent hypnotics. The number of carbon atoms in groups occupying this position should be between four and eight, one group being aliphatic. The use of some of the newer derivatives for producing basal anaesthesia has stimulated interest in this group, but there appears no distinct division into those which can be used for this purpose and those which are only useful as hypnotics. The table below gives the constitution of the groupings occupying the 5 : 5'-positions in malonylurea in the more important members of this group.

Phemitone and hexobarbitone illustrate a new departure—the formation of such compounds from methylurea instead of from urea.

The open chain ureides are much less active and much less toxic than the barbiturates, e.g., carbromal.

| B.P. Name. | | | | Proprietary Name. |
|-------------------|--|--|---------------|-------------------|
| Barbitone .. | $-\text{C}_2\text{H}_5$ | $-\text{C}_2\text{H}_5$ | H | Veronal |
| Phenobarbitone .. | $-\text{C}_6\text{H}_5$ | $-\text{C}_6\text{H}_5$ | H | Luminal |
| Phemitone .. | $-\text{C}_2\text{H}_5$ | $-\text{C}_6\text{H}_5$ | CH_3 | Prominal |
| Hexobarbitone .. | $-\text{CH}_3$ | | CH_3 | Evipan |
| | $-\text{CH}_2 \cdot \text{CH} = \text{CH}_2$ | $-\text{CH}_2 \cdot \text{CH} = \text{CH}_2$ | H | Dial |
| | $-\text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_3$ | $-\text{CHBr} \cdot \text{CH} = \text{CH}_2$ | H | Pernocton |
| | $-\text{C}_2\text{H}_5$ | | H | Phanodorm |
| | $-\text{C}_2\text{H}_5$ | $-\text{CH}_2 \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{CH}_3$ | H | Nembutal |
| | $-\text{C}_2\text{H}_5$ | | H | Amytal |

Bactericides. The cresols are approximately $2\frac{1}{2}$ times as active as phenol whilst with thymol the figure reaches 25. Toxicity is reduced with increase of molecular weight. Johnson and Lane (1921) determined the phenol coefficients for a series of 4-alkylresorcinols which increase up to the hexyl derivative (50) and then decrease (Dohme, Cox and Millar, 1926). Coulthard, Marshall and Pyman studied the variation of phenol coefficient with increase in the *n*-alkyl-side chain in the 4-*n*-alkylphenols, 4-*n*-alkylguaiacols and 4-*n*-alkyl-*m*-cresols. The *n*-amyl derivative was always the most active and the alkylcresols were all more active than the alkylphenols whilst the alkylguaiacols occupy an intermediate position. 4-*n*-Amyl-*m*-cresol exhibited a phenol coefficient of 280 and had about half the toxicity of hexylresorcinol. Attention has also been directed to the chloro derivatives of cresols and xlenols by the success of certain proprietary disinfectants, e.g.,

The number in the ring is the phenol coefficient. In the series represented by the two latter formulæ R must be butyl and amyl respectively to obtain greatest activity.

All phenol coefficient figures must be regarded with reserve as they refer only to one organism and to a particular set of experimental conditions. The figures may vary widely with different bacteria, but they are useful in providing a rough classification of compounds belonging to closely related series.

Derivatives of 2:8-diamino-acridine (VII) occupy a special position in the treatment of wounds as they are not inactivated in presence of serum. Their introduction is mainly due to the work of Browning in 1917.

Proflavine is the sulphate of (VII); acriflavine is a mixture of the hydrochlorides of (VII) and (VIII); whilst euflavine is a mixture of (VII) and (VIII). Albert and Linnell (1935-1938) prepared all the possible monoaminoacridines and diaminoacridines.

It was found that all compounds containing a 1-amino substituent were inactive and showed no fluorescence in solution. Amino groups in positions 2, 3, 4 and 5 increased the antiseptic activity of the acridine molecules, but toxicities and bacteriostatic properties were not parallel. 2:7-Diaminoacridine was found to be the best of this series of compounds and its toxicity, compared with the commercially available flavines, was 2:7-diaminoacridine, 1; proflavine, 2.5; acriflavine, 10. Later work of Falconer and Russell (*Proc. R. Soc. Med.*, 1940, 33, 494) has centred attention on 2:7-diaminoacridine as the best available antiseptic for the treatment of injuries to the living brain, whilst Manifold (*ibid.*, 1940, 33, 498; also *Brit. med. J.*, 1940, 631) has shown that it is much less toxic to brain tissue than acriflavine or proflavine. Linnell and collaborators have extended the exploration of the acridine nucleus to derivatives of dihydroacridine (the acridanes), the chloro-amino derivatives and the chloroalkoxy compounds (see *Quart. J. Pharm.*, 1938, 240; 1940, 162; 1942, 31; *J. chem. Soc.*, 1942, 377).

Organic Arsenicals. Bunsen first drew attention to the fact that cacodylic acid was almost non-toxic but Armand Gautier was the first to introduce organic arsenic compounds into medicine.

An aliphatic derivative containing arsenic, Arrhenal, $\text{CH}_3\text{AsO}(\text{ONa})_2$, is used as a general tonic but such substances are without action upon spirilla and trypanosomes whereas the aromatic compounds have a pronounced effect. Atoxyl, *p*-amino-arsonic acid, was used in control of sleeping sickness, of which the causal agent is *Trypanosoma gambiense*, although *in vitro* it exhibits no action against trypanosomes. Ehrlich supposed that it was reduced in the living organism and that the product was the actual agent in the trypanocidal action. Although this view has not been entirely substantiated it led to the introduction of Salvarsan (arsphenamine) and its derivatives neoarsphenamine and sulpharsphenamine, in which the arsenic is in the trivalent condition and which possess a much more satisfactory gap between the curative and the toxic doses. Arsenophenylglycine, another compound of trivalent arsenic, is very active in trypanosomiasis but has no action in spirillosis, whilst the reverse holds true for arsphenamine. The superiority of trivalent arsenic compounds has not been substantiated as tryparsamide, sodium *N*-phenylglycineamide-*p*-arsonate, and acetarsol, 3-acetylamin-4-hydroxyphenylarsonic acid, both contain the arsenic in the pentavalent condition: these compounds have the great advantage of being well defined crystalline identities which may be completely standardised by chemical analysis whereas the arsphen-

mines require a biological toxicity test in addition. Acetarsol was the first compound containing organic arsenic which exerted its effect when taken by mouth.

During the period 1931-1936 an extensive series of new organic arsenical compounds has been prepared at the Chemical Research Laboratory, Teddington, under the direction of Sir Gilbert Morgan, with the object of replacing or supplementing tryparsamide. The compounds possessed the general formula (IX) which combined in one structure the acyl and amide types represented by acetarsol (X) and tryparsamide (XI) respectively.

From over 100 active compounds, sodium succinylomethylamide-*p*-arsonate (Fig. IX, $n=2$, $\text{R}_1=\text{H}$, $\text{R}_2=\text{CH}_3$), now known as Neocryl, has been selected for human trials under the auspices of the Therapeutic Trials Committee of the Medical Research Council. It is still too early to give a final opinion as to the value of Neocryl but it appears to be much less toxic than tryparsamide.

Streptococcicides. One of the most important developments of recent years has been the introduction of derivatives of *p*-aminobenzenesulphonamide (XV), following the work of Domagk (1935), as specifics in streptococcal infections. Domagk found that the dye, 4'-sulphamido-2:4-diaminoazobenzene, known as Prontosil (red) (XII) had the property of protecting mice against infection with virulent strains of hæmolytic streptococci. A soluble form (XIIa) was also introduced for parenteral administration: these substances have a potent action on streptococci localised in the body although they have little action *in vitro*.

It was established that the active fragment of these dyes was *p*-aminobenzenesulphonamide (XIV) and that this compound was formed in the animal organism by scission (Buttle, Gray and Stephenson, *Lancet*, i/1936, 1286; Kellner, *Thèse*, 1936, Paris; Fuller, *Lancet*, i/1937, 194). The results obtained with substances of this class against strepto-, pneumo- and staphylococcal diseases such as pneumonia and puerperal septicaemia, were often miraculous and hence it is not surprising that the subject has attracted large numbers of research workers. Up to 1940 some 3000 derivatives of *p*-aminobenzenesulphonamide had been prepared and tested. As a result of this work it is probably correct to say that a nitrogen *para* to a sulphur atom in a benzene ring (XIV) is essential for activity.

(XIII)

(XIV)

The related *ortho* and *meta* compounds of (XIV) are inactive. The hydrogens of the *p*-amino group may be replaced by a number of substituents without complete loss of activity; the hydrogens of the sulphonamide group may also be replaced by certain radicals whilst the activity is retained. The corresponding *p*-aminobenzenesulphonic acid, *p*-hydroxybenzenesulphonamide, and benzenesulphonamide itself, have little activity. Nuclear substitution of

the ring carrying the *p*-nitrogen and sulphur almost invariably causes complete inactivity, although other cyclic systems attached via substitution of the amino group can be varied in many ways.

In addition to sulphanilamide (XIV) a comparatively small number of sulphonamide derivatives are in common use, of which the following are the most important:—

Sulphapyridine
(XV)

Sulphathiazole
(XVI)

Sulphadiazine
(XVII)

Sulphanilamide, which is by far the cheapest substance of this group, should be used when contrary indications are absent. Sulphapyridine appears to have become established as the best derivative for certain types of pneumonia. The claims of sulphathiazole and sulphadiazine to attention are based upon lower toxicity, but they have been available for too short a time to make any firm statement about them. Sulphadiazine is stated to be particularly free from toxic effects and a high concentration may be maintained in the blood (*Brit. med. J.*, i/1942, 16).

The toxic effects of these derivatives are usually not of serious moment but can be very unpleasant and one of the major objectives of research is the reduction or elimination of this toxicity.

Sulphanilylguanidine, $p\text{-NH}_2\text{-C}_6\text{H}_4\text{-SO}_2\text{-NH}\cdot\text{C}(\text{:NH})\cdot\text{NH}_2$, the preparation of which has been described by Anderson and Cruickshank (*Brit. med. J.*, ii/1941, 497) is a compound which is said to be valuable as an intestinal antiseptic in the treatment of bacillary dysentery. The preparation of the compound (XVIII) is protected by patent (Brit. Pat. 531957) and antimalarial activity is claimed for it. If this is substantiated, it will extend the usefulness of the sulphonamides to another important field.

Little success has been encountered to date in introducing the sulphonamide group into other important chemical nuclei; for instance, the acridine derivatives so far obtained have been disappointing.

Future work on the sulphanilamide molecule has the dual objective of reducing toxicity and, by varying the molecule, extending its usefulness against other organisms.

Sulphones. Certain sulphones, such as pp' -diaminodiphenylsulphone (XIX), have been found to possess a much greater activity than sulphanilamide, but, unfortunately, this was coupled with a greater toxicity. The sulphone molecule, however, appeared to be less susceptible to loss of activity by modification than sulphanilamide. For instance, the diacetyl derivative (XX) retained much of the activity of the parent body, but was much less toxic. Again, the corresponding sulfoxide (XXI) and sulphide (XXII) still possessed some activity.

(XIX)

(XX)

(XXI)

(XXII)

(XXIII)

(XXIV)

For these reasons this sulphone molecule may provide an even more fruitful source of new compounds than sulphanilamides. Roblin, Williams and Anderson (*J. Amer. chem. Soc.*, 1941, *63*, 1930; *Chem. Abstr. A.* 1942, *II*, 119) have prepared a series of compounds related to (XIX), two of which (XXIII, XXIV) were highly active against streptococcal and pneumococcal infections in mice, but less toxic than the type. The compound (XXIV) is most interesting when compared with sulphapyridine (XV). It may be that the introduction of the pyridine molecule into the sulphone field will yield as interesting results as it did amongst the sulphanilamides. Encouraging results have been obtained by Feldman (*Proc. Mayo Clin.*, 1941, 187; 1941, *III*, 125) in the treatment of tuberculosis in guinea-pigs with "promin," the sodium salt of the NN'-diglucosesulphonate of (XIX); its value in human infections is not yet established.

An excellent summary of the early work in this series will be found in the *Chemical Review* for 1940.

Sex Hormones. A remarkable instance of the changes in function following comparatively small changes in chemical

constitution is afforded by the natural substances based upon the cyclopentenophenanthrene skeleton (XXV). The table on p. 494,

illustrates the main types of compounds belonging to this class of substances, and it should be immediately apparent that fundamental differences in physiological effect are accompanied by comparatively slight changes in chemical constitution.

It will be noticed that throughout this series of substances, from cholesterol to testosterone there is a progressive shortening of the side chain at C_{17} . The main difference between progesterone and corticosterone appears to lie in the constitution of the C_{17} group. That the $-\text{CO}\cdot\text{CH}_2\text{OH}$ in corticosterone is important has recently been demonstrated by Linnell and Roushdi (*Quart. J. Pharm.*, 1939, 252; *ibid.*, 1941, 270; *Nature, Lond.*, i/1941, 595), who have produced two synthetic compounds containing this group which possessed biological activity similar to that of corticosterone.

The main difference between the male and female sex hormones appears to be in the degree of unsaturation.

A considerable amount of work concerning the relationship between chemical constitution and physiological activity amongst the oestrogens, has been done in recent years. Varying oestrogenic activity (ranging from compounds showing small but definite activity to those 10,000,000 times more potent) has been found in derivatives of phenanthrene (*see* rings A, B, C), anthracene, diphenyl, diphenylmethane and stilbene.

Dodds, Goldberg, Lawson and Robinson (*Nature, Lond.*, i/1938, 247; cf. *Lancet*, ii/1938, 1389) produced 4:4'-dihydroxy- α : β -diethylstilbene (stilboestrol, XXVI), which was actually slightly more potent than the natural hormone. If figures XXVI and XXVII are observed an apparent similarity in molecular

| Type | Example | Double Bonds | Carbon atoms | | | | Other variations |
|-------------------|------------------|----------------------------|--------------|-----------------|-----------------|---|------------------|
| | | | 3 | 10 | 13 | 17 | |
| Sterol .. | Cholesterol .. | $\Delta^5(6)$.. | OH | CH ₃ | CH ₃ | -CH(CH ₃)·CH ₂ ·CH ₂ ·CH ₂ ·CH ₂ ·(CH ₃) ₂ | |
| | Ergosterol .. | $\Delta^5(6,7-8)22(23)$ | OH | CH ₃ | CH ₃ | -CH(CH ₃)·CH = CH·CH(CH ₃)·CH(CH ₃) ₂ | |
| Cardiac Glycoside | Strophanthidin | — | OH | -CHO | CH ₃ | — | 5-14-dihydroxy |
| Bile Acid .. | Lithocholic Acid | — | OH | CH ₃ | CH ₃ | — | — |
| | Progesterone .. | $\Delta^4(6)$.. | -O | CH ₃ | CH ₃ | -CO·CH ₃ | — |
| Steroid Hormones | Corticosterone | $\Delta^4(6)$.. | -O | CH ₃ | CH ₃ | -CO·CH ₂ ·OH | 11-hydroxy |
| | Testosterone .. | Δ^4 .. | -O | CH ₃ | CH ₃ | -OH | — |
| | Œstradiol .. | $\Delta^{1(2)-3(4)-5(16)}$ | -OH | — | CH ₃ | -OH | — |

outline of this compound and œstradiol can be seen and it was suggested that this similarity might account for the remarkably high potency of the synthetic compound. Hexœstrol—in which the aliphatic double bond of stilbœstrol is reduced—is even slightly more active (see Docken and Spielman, *J. Amer. chem. Soc.*, 1940, 62, 2163, *Chem. Abstr. A*, 1940, 11, 342).

Rings W' and W are the same in each compound; rings X and Y may be considered to be simulated by the open chain structure X' Y'; ring Z' may be made by incorporating the angular methyl group into ring Z. On the other hand, the differences between the two structures are more fundamental: œstradiol has a condensed ring structure and this does not apply to stilbœstrol; the degree of saturation in the two compounds is widely different; both hydroxyls in stilbœstrol are phenolic, whereas in œstradiol one of them is a secondary alcohol. If this simulation of architectural plan is of moment, it appears that the 3 : 4'-dihydroxy analogue of stilbœstrol is closer to the structure of œstradiol than the 4 : 4'-dihydroxy compound as the C₁₇ hydroxyl is on the carbon "next door" to ring Y. Linnell and Sharma (*Quart. J. Pharm.*, 1941, 259) prepared this compound and found it to be much less active than stilbœstrol. It is probable, therefore, that simulation of architectural plan does not account for the high activity.

Linnell and Shaikhmahamud have prepared the compound (XXVIII) which simulates the structure of œstradiol to the same degree as stilbœstrol, but in a different manner. It will be noticed that the ethyl groups forming X'' and Y'' (XXVIII) are carried

by the nuclei W and Z and not by the α : β -carbons as in X' Y' (XXVI).

If the simulation theory were sound the compound would be expected to possess an activity of the order of stilbœstrol or œstradiol: if this is not true it should fall into place as a homologue of 4 : 4'-dihydroxystilbene. The compound was found to be active in doses of about 2 mg. (the figure for stilbœstrol is about 0.1 γ) and thus was placed in the latter category.

As a result of these studies Linnell and collaborators suggested that the molecular fragment of importance for œstrogen activity was the skeleton of 4-hydroxypropylbenzene (XXIX). Stilbœstrol can be considered as two such fragments joined through their α -carbon atoms; it may be discerned in the natural œstrogens in ring W plus carbons 9, 11, 12 (XXVII); it is not present in the molecule of (XXVIII). The above short summary of work in this field provides a good example of the methods used in addressing the problem of the relationship between chemical constitution and physiological effect.

ACTION OF ACIDS ON THE COMMON METALS AND THEIR OXIDES

The reaction between acids and the common metals is a matter frequently arising and one concerning which information is not always available.

A SCHEME FOR THE RECOGNITION OF ORGANIC CHEMICAL SUBSTANCES USED IN THERAPEUTICS

The following scheme is intended to assist in the recognition of a number of organic chemicals, both natural and synthetic, used therapeutically. It frequently happens that the analyst is called upon to identify such substances, and without a systematic method of examination accurate results may be extremely difficult to obtain.

Before commencing the analysis it should be ascertained, for example by treatment with solvents, whether the sample is one compound or a mixture, and if the latter a separation by chemical or physical means should be effected. No general rule for the isolation of the constituents can be given, but fractional distillation, crystallisation and solution methods are usually used, and extraction from an acid or alkaline aqueous solution with an immiscible solvent is often helpful when one component has basic or acidic properties.

The Preliminary Tests are first carried out, and by comparison of the results with the tables, some idea of the nature of the substance may be obtained, enabling corroborative tests to be at once applied. If, however, no satisfactory evidence is obtained from the preliminary tests, it is determined whether the substance contains nitrogen, sulphur, halogens or phosphorus, a more complete classification for the purposes of identification being based on the elements present.

PRELIMINARY TESTS

1. The Action of Heat

A small quantity of the substance is heated on a piece of foil or porcelain and the odour, behaviour, and presence of any inorganic residue is noted.

| OBSERVATIONS | COMPOUNDS |
|---------------------------|--|
| ODOUR on heating: | Given by:— |
| (i) Very objectionable | Acriflavine, Benzocaine, Carbromal, Physostigmine, Yohimbine. |
| (ii) Garlic-like ... | Chloralamide, Disodium Methylarsonate, Neoarsphenamine, Sodium Aminarsonate, Sodium Cacodylate, Sulphonal, Thiosinamine. |
| (iii) "Burning sugar" ... | Citrates, Lactates, Mandelates, Tartrates, Sugars, Calcium Saccharate, Picrotoxin, Strophanthin. |

| OBSERVATIONS | COMPOUNDS |
|---|--|
| ODOUR on heating: | Given by:— |
| (iv) Resembling pyridine (or "burnt feathers") | The Purine Bases, Caffeine, etc., and their compounds. |
| (v) Phenolic | Amidopyrine, Apomorphine, Morphine, Cinchona alkaloids, Malachite Green, Phenazone Amylocaine Hydrochloride, Strychnine. |
| (vi) Aromatic | Inorganic Benzoates, Salicylates and Phenol-sulphonates, Phenol compounds. |
| (vii) "Sweetish" odour ... | Potassium Hydroxyquinoline Sulphate, Tribromophenol, Chlorocresol, Chloroxyleneol. |
| (viii) "Alcoholic" ... | The characteristic odour of Salicylic Acid on heating is obtained with all its organic derivatives. |
| (ix) Amine odour ... | Aconitine, Atropine, Cinchophen, Cocaine, Colchicine, Hyoscyne, Papaverine, Cinnamates, Benzoates, Hippurates. |
| (x) Odour of burning animal or nitrogenous matter | Allantoin, PicROTOXIN, Resorcinol, Saccharin, Ethylmorphine. |
| (xi) Acetous odour ... | Chlorbutol, Homatropine, Soluble Barbitone, Urethane. |
| (xii) Odour of geranium leaves | Amydracaine Hydrochloride, Amylocaine Hydrochloride, Apomorphine, Betaine, Colchicine, Ethylmorphine, Hexamine, Papaverine, Pilocarpine, Piperazine, Sodium Hippurate, Urea, Emetine Hydrochloride. |
| | Albumin Tannate, Bile Salts, Nuclein, Silver Proteinates. |
| | Atropine, Acetomenaphthone. |
| | Amphetamine. |
| APPEARANCE on heating: | |
| (i) Low-melting solids (below 100°) | Acetophenone, Stearic Acid, Benzocaine, Chloral Hydrate, Chlorbutol, Cocaine, Colchicine Salicyl., Coumarin, Guaiacol, Homatropine, Phenazone Salicylate, Physostigmine, Salol, Thiosinamine, Thymol, Tribromophenol, Urethane, Nikethamide, Cetyl Alcohol, Tribromoethyl Alcohol, Chlorocresol, Leptazol, Nupercaine. |
| (ii) Coloured fumes | Alkaloidal Periodides, Emet. Bism. Iodide, Iodoform, Thymol Iodide, Tetraiodopyrrol. |
| (a) of Iodine | Acriflavine, Chrysarobin, Colchicine, Fluorescein. |
| (b) Yellowish-brown | |
| (iii) Coloured residue— | |
| (a) Violet ... | Sulphanilamide. |
| (b) Brown (with evolution of sulphur dioxide) ... | |
| Brown (with odour of ammonia and mercaptan) ... | Sulphapyridine. |
| (iv) Yellow sparks | Sulphathiazole. |
| (v) Decomposes or volatilises without appreciable charring. | Gallic Acid, Alum. Aceto-tart., Zinc Phenol-sulphonate, Urea. |
| | Acetylsalicylic, Malic, Oxalic and Succinic Acids, Caffeine, Theobromine, Amphetamine, Phenacaine, Chloralamide, Naphthalene Tetra-chloride, Phenazone, Piperazine, Urea. |

If an inorganic residue is obtained on ignition the substance is probably the metallic salt of an organic acid or phenol, and the following compounds, classified according to the metal present, are frequently employed therapeutically. In most cases tests for the acidic radicle, which can usually be separated as the sodium salt by treatment of the substance with alkali, are described later.

| THE METAL PRESENT IN RESIDUE AFTER IGNITION | COMPOUNDS TO BE EXAMINED FOR:— |
|---|--|
| Aluminium | Aceto-tartrate. |
| Antimony | |
| (with Sodium) | Sodium Antimonytartrate, Stibophen. |
| (with Potassium) | Potassium Antimonytartrate. |
| Bismuth | |
| (with Sodium or Potassium or both) | Alkali Bismuthyl Tartrates, Benzoate, Citrate, Gallate, Oxyiodogallate, Naphthol, Tribromophenol, Salicylate, etc. |
| Calcium | Acetylsalicylate, Formate, Lactate, Gluconate, Levulinate, Glycerophosphate, Saccharate, Guaiacolsulphonate. |
| Iron | Ammon. Citrate, Tartrate, Oxalate, etc. Glycerophosphate, Peptonate, Valerianate. |
| Magnesium | Acetylsalicylate, Glycerophosphate, Ricinoleate. |
| Manganese | Butyrate, Glycerophosphate. |
| Mercury | Mersalyl, Phenylmercuric Nitrate. |
| Potassium | Acetate, Oxalate, Borotartrate, Citrate, Formate, |
| Silver | Colloidal, Proteinate, Nucleinate, etc. [etc. |
| Sodium | Indigo Carmine. Soluble Barbitone, Phenobarbitone, and Hexobarbitone, Phenytoin Soluble, Sodium Amytal, Iodoxyl, Suramin, Nembutal, Soluble Sulphanilamides, Mercurochrome, Neoarsphenamine, Acetate, Formate, Glycerophosphate, Salicylate, etc. Bile Salts. |
| Zinc | Oleate, Phenolsulphonate, Valerianate. |

2. The Action of Concentrated Sulphuric Acid

About 0.2 g. of the substance is treated with 1 ml. of sulphuric acid at first cold and then with heating.

| OBSERVATIONS | COMPOUNDS |
|---------------------------------|---|
| Cold Sulphuric Acid:— | |
| <i>Insoluble</i> | Saturated and aromatic hydrocarbons and their halogen derivatives:—Benzene, Xylene, etc. |
| Effervescence— | |
| (i) HCl, HBr, HI | From salts with organic bases, e.g.:— Acetyl- β -methylcholine Chloride, Aneurine Hydrochloride, Mepacrine Hydrochloride, Alkaloidal Hydrochlorides, Acriflavine, Betaine Hydrochloride, Procaine Hydrochloride, Amethocaine, etc. |
| (ii) Chlorine | Chloramine and Dichloramine-T. |
| Odour of Sulphur Dioxide | Neoarsphenamine, Sulphapyridine. |
| Coloration— | |
| (i) Deep red | With certain glycosides, e.g.:— Salicin, Amygdalin, Arbutin. Aloes, Acriflavine, Iodised Oils, Proflavine, Phenolphthalein, Santalol. |

| OBSERVATIONS | COMPOUNDS |
|--|--|
| <i>Coloration—</i> | |
| (ii) Light red ... | Nicotine, Physostigmine. |
| (iii) Green ... | Methylene Blue. |
| (iv) Blue ... | Strophanthin (changes to brown). Amyl Nitrite (changes to brown). |
| Hot Sulphuric Acid:— | |
| <i>Effervescence—</i> | |
| (i) Without charring | Formic Acid, Oxalic Acid, Betaine Hydrochloride, Urea. |
| (ii) With blackening | Carbohydrates, some glycosides, Hydroxyacids such as Citric, Tartaric, Lactic. |
| <i>Iodine evolved ...</i> | Apiol, Malachite Green. |
| <i>Pungent Vapours—</i> | Ethyl Iodide, Bismuth Oxyiodogallate, Emetine |
| Without effervescence and blackening ... | Bismuth Iodide, Thymol Iodide, Tetraiodopyrrol, Diodone, Iodoxyl. |
| <i>No blackening ...</i> | Acetic, Benzoic, Salicylic, Succinic, Acetylsalicylic Acids, Phenols and metallic derivatives, Brometone, Chlorbutol, Chloral Hydrate. |
| | Benzoic, Salicylic, Acetylsalicylic Acids and many of their compounds; Phenol. |
| | Allantoin (red soln.), Alloxan (yellow soln.), Amidopyrine, Amydicaine Hydrochloride, Chloralamide (chloral odour), Ethyl Bromide |
| | Fluorescein, Purine Bases. |

3. The Action of Alkali

To about 0.5 g. of substance, add strong sodium hydroxide solution and warm.

| OBSERVATIONS | COMPOUNDS |
|---|--|
| <i>Substance dissolves ...</i> | Acids, Amides, Barbiturates, Sulphanilamides, Phenols, Halogen deriv. of Phenols, some Esters, etc. |
| <i>Precipitate forms ...</i> | This may be hydroxide from metallic salt (which would be detected in Test 1). Organic Base from Salts (Morphine dissolves in excess). |
| <i>Odour of Ammonia ...</i> | From Ammonium Salts, Amides, Carbachol, Diphenan, Phemitone, Ureides, Urea compounds, Chloralamide. |
| <i>Odour of Amine ...</i> | From salts, e.g., Aniline Hydrochloride, Acetanilide, Methylacetanilide. |
| <i>Odour of Pyridine ...</i> | Nicotinic Acid. |
| <i>Coloration—</i> | |
| (i) Deep red... .. | Phenolphthalein. |
| (ii) Yellow cold turning red on warming | Many sugars. |
| <i>Fluorescence ...</i> | Dithranol, Fluorescein, Eosin. |

4. Reactions for Alkaloids

The solution should be tested for alkaloids by means of the usual reagents such as Mayer's reagent, gold chloride or picric acid. The table below may be useful in the identification of a common alkaloid (see page 514 *et seq.*)

In addition to the synthetic Cocaine substitutes the following bodies react in some cases like alkaloids:—

Amidopyrine, Phenazone, Piperazine, Piperidine, Potassium Hydroxyquinoline Sulphate, Pyridine, Quinoline, Thiosinamine, and some dyes such as Acriflavine.

The purine bases, Caffeine, Theobromine, Theophylline, do not respond to many of the usual tests.

5. Reaction with Fehling's Solution

It should be determined whether the substance reduces Fehling's before and after hydrolysis with dilute acid.

| | |
|---|--|
| Substances readily reducing Fehling's Solution before hydrolysis. | Monosaccharides: Dextrose, Lævulose, Mannose, etc. Disaccharides: Lactose, Maltose, etc. Fehling's is also reduced by some aldehydes, e.g., Chloral, and polyhydric phenols, e.g., Resorcinol, Pyrogallol, and by Amylocaine Hydrochloride, Camphoric Acid, Chloroform, Chloralamide. |
| Substances readily reducing Fehling's Solution only after hydrolysis. | Disaccharides: Sucrose. Glycosides: Aesculin, Salicin, etc. |

EXAMINATION FOR ELEMENTS

The compound should be examined systematically for non-metallic elements including nitrogen, sulphur, halogens and phosphorus. Lassaigne's method is usually satisfactory, and consists in adding about 0.1 g. of the substance to a small piece of clean molten sodium in a test-tube, and, after thorough heating, the mass is carefully treated with water and filtered.

Nitrogen

A portion of the above solution is tested for cyanide by heating with ferrous sulphate, making acid with hydrochloric acid and adding 1 drop of ferric chloride solution. A blue solution or precipitate of Prussian blue indicates the presence of nitrogen in the substance. Cyanamide, given by urea and derivatives, should also be tested for by means of silver nitrate, the silver salt being soluble in nitric acid but insoluble in ammonia. Sodium thiocyanate may be formed if the substance contains nitrogen and sulphur.

Sulphur

The formation of a deep violet colour on adding a small crystal of sodium nitroprusside to some of the solution from the sodium ignition indicates the presence of sulphur. The solution may also be tested for sulphide by means of lead acetate.

Halogens

These are identified in the usual way, after removal of hydrocyanic acid if necessary, by boiling some of the above solution with nitric acid.

Phosphorus

This element can be detected as phosphate after ignition of the substance with potassium carbonate and potassium nitrate.

It is now possible to decide to which of the following groups the unknown compound belongs:—

- GROUP I. *Organic compounds not containing halogens, nitrogen, sulphur or phosphorus.*
- GROUP II. *Compounds containing halogens* (and free from phosphorus, sulphur or nitrogen).
- GROUP III. *Compounds containing nitrogen* (and free from halogens, sulphur and phosphorus).
- GROUP IV. *Compounds containing sulphur* (and free from halogens, nitrogen and phosphorus).

GROUP V. *Compounds containing nitrogen and sulphur* (and free from halogens and phosphorus).

GROUP VI. *Compounds containing nitrogen and halogens* (and free from sulphur and phosphorus).

GROUP VII. *Compounds containing halogens, nitrogen and sulphur* (phosphorus absent).

GROUP VIII. *Compounds containing phosphorus.*

The distinguishing tests in each group, which should be carried out in the order given, together with a knowledge of the physical properties of the substance, should enable it to be identified with the aid of the special tests in the Corroborative Chart. When the groups contain a large number of compounds they are divided, as far as possible, according to their chemical type, which should enable any uncommon medicinal body, not mentioned in the scheme, to be classified.

GROUP I. Organic Compounds not containing Halogens, Nitrogen, Sulphur or Phosphorus.

1. Acids

By treatment with sodium carbonate or by an approximate titration, using N/1 sodium hydroxide and phenolphthalein, it should be determined whether the substance is an acid. A neutral solution of the sodium salt is then tested with ferric chloride and calcium chloride, the behaviour of some common acids being shown in the following table. The polyhydric phenols, such as pyrogallol, and also a few acids containing nitrogen, although not belonging to this group, are also included for convenience.

Table of The Common Acids

| REAGENT | OBSERVATIONS | ACIDS |
|-----------------|--|---|
| Ferric Chloride | <i>Purple Coloration.</i> | |
| | (i) Not discharged by acetic acid. | Salicylic Acid. Acetylsalicylic Acid also gives this on warming with the reagent. |
| | (ii) Discharged by acetic acid. | Phenol. |
| | <i>Yellow Coloration.</i> | Mandelic Acid. |
| | <i>Red Coloration.</i> | |
| | (i) Discharged by HCl to yellow colour. | Formic and Acetic Acids. |
| | (ii) Not discharged by HCl but by HgCl_2 . | Sulphocyanic Acid. |
| | (iii) Not discharged by HCl or HgCl_2 . | Meconic Acid. |
| | (iv) Blackened by excess of KOH solution. | Pyrogallol. |
| | <i>Coloured Precipitate.</i> | |
| | (i) Buff coloured. The addition of HCl gives white crystalline body. | Benzoic, Hippuric and Cinnamic Acids. |
| | (ii) Reddish-brown ppt. | |
| | (a) Giving clear solution with HCl. | Succinic and Phthalic Acids. |
| | (b) White crystals with HCl. | Uric Acid. |
| | (iii) Blue-black, giving brown solution with H_2SO_4 . | Gallic and Tannic Acids. |
| | (iv) Prussian blue, discharged by NaOH. | Ferrocyanic Acid. |
| | (v) Brown solution giving Prussian blue on adding SO_2 . | Ferricyanic Acid. |

| REAGENT | OBSERVATIONS | ACIDS |
|--|---|---|
| Calcium Chloride to cold solution. | (i) White precipitate soluble on boiling. (ii) White ppt. soluble in HCl but insoluble in acetic acid. (iii) Crystalline powder soluble in HCl and acetic acid. | Malonic Acid. Oxalic Acid. Tartaric, Fumaric Acids. |
| Calcium Chloride on boiling. | (i) White ppt. on adding 1 drop ammonia solution, and soluble in acetic acid. (ii) White ppt. on adding equal volume of alcohol. Soluble in acetic acid. (iii) Greyish-white ppt. Soluble in HCl to pinkish solution. | Citric Acid. Malic Acid. Tannic and Gallic Acids. |

Other acids which should be tested for are Cacodylic, Camphoric, Coumaric, Valerianic, Gluconic, Levulinic and Lactic. Oleic and Stearic acids have a characteristic appearance.

2. Phenols and Lactones

The presence of these compounds is indicated by solubility in sodium hydroxide solution but not in sodium carbonate.

PHENOLS.—Phenol, Thymol, α - and β -Naphthol, Cresol, Xylenol.

LACTONES, dissolving slowly in hot alkali and reprecipitated by acid:—Coumarin (has characteristic odour and gives yellow solution with caustic alkali), Santonin.

3. Aldehydes and Ketones

Aldehydes reduce ammoniacal silver nitrate and give colour with Schiff's reagent. Ketones and aldehydes form derivatives with phenylhydrazine and semicarbazide, the melting-points of which are useful for identification, and many give crystalline compounds with sodium bisulphite.

The following should be tested for:—Acetaldehyde, Formaldehyde, Paraformaldehyde, Benzaldehyde, Acetone, Acetophenone, Metaldehyde, Paraldehyde.

4. Esters

These compounds, when hydrolysed by alkali, yield an acid and an alcohol or phenol.

(i) Esters derived from alcohols usually have a pleasant odour.

Ethyl Acetate, Amyl Valerianate, Methyl Salicylate, Benzyl Benzoate and Succinate, Methyl and Propyl Hydroxybenzoates.

(ii) Esters derived from phenols and used therapeutically are often compounds of either Salicylic Acid or Guaiacol.

Salicyl Salicylate, Salol, Guaiacol Benzoate, Cinnamate, Carbonate, Camphorate, Salicylate, Valerianate.

5. Hydrocarbons

These are insoluble in cold sulphuric acid; aromatic compounds have characteristic odour, and must be identified by physical properties.

Benzene, Light Petroleum, Toluene, Xylene, Paraffin.

6. Mercury Compounds

The substance should be tested for mercury after destroying organic matter with concentrated sulphuric and nitric acids.

Common compounds are the Benzoate, Lactate, Oleate, Phenate, Salicylate, Succinate, Succinimide, Mercurochrome, Mersalyl, Phenylmercuric Nitrate.

7. Compounds Soluble in Water

CARBOHYDRATES (except Starch and Cellulose). *Aliphatic Alcohols, Glycosides* (moderately soluble), *Polyhydric Phenols*.

(i) Sugars and Glycosides.

These would have been indicated by Preliminary Test 5. Glycosides likely to be present are:—Digitalin, Digoxin, Digitoxin (not very soluble in water), Salicin, Phloridzin, Strophanthin.

(ii) Common Alcohols.

Methyl, Ethyl, Propyl and Isopropyl, Amylene Hydrate (camphoraceous odour).

(iii) Polyhydric Phenols.

Resorcinol, Pyrogallol.

8. Substances having Characteristic Physical Properties

The following members of this group can be recognised by properties such as odour and appearance.

| LIQUIDS | | SOLIDS | |
|---|---|-----------------------|--|
| SUBSTANCE | DISTINGUISHING PROPERTY | SUBSTANCE | DISTINGUISHING PROPERTY |
| Apiol (may, however, be crystalline) | Green liquid. Peculiar odour. | Aloes, Aloin | Yellowish-brown with characteristic odour. |
| Amyl Alcohol | Characteristic odour. | Coumarin | Fragrant odour. Sublimes at 100°. |
| Capsicin | Reddish-brown oily mass. | Podophyllin | Characteristic odour. |
| Resorcinol Monoacetate | Oily substance with slight acetic acid odour. | Acetophenone | Odour resembling almonds and jasmine. |
| Santalol | Characteristic odour. | Terpin Hydrate | Slightly aromatic odour. Sublimes at 100°. |

Test specially for the neutral compounds Podophyllotoxin, Cantharidin, Elaterin.

GROUP II. Compounds containing Halogens. (Nitrogen, Sulphur and Phosphorus being absent.)

The following are commonly occurring substances:—

CHLORINE COMPOUNDS.

Amylene Chloral, Butylchloral, Ethyl Chloride, Carbon Tetrachloride, Chlorbutol, Chloral Hydrate, Chloroform, Chlorocresol, Chloroxyleneol, Chlorobenzenes, Naphthalene Tetrachloride.

BROMINE COMPOUNDS.

Bromal Hydrate, Bromoform, Camphor Monobromide, Ethyl Bromide, Tribromophenol, Tribromoethyl Alcohol, Bromural.

IODINE COMPOUNDS.

Ethyl Iodide, Thymol Iodide, Thyroxin, Iodised oils.

GROUP III. Compounds containing Nitrogen. (Halogens, Sulphur and Phosphorus being absent.)**1. The Alkaloids**

Members of this class of compounds, including some synthetic cocaine substitutes, would be indicated by Preliminary Test 4.

In the following table most of the substances in general use are arranged according to their behaviour with certain reagents, and by testing with these

in the order named it is possible to determine rapidly in which group an unknown alkaloid occurs, when it is identified by physical properties and special reactions.

In each test about 2 ml. of a 1% solution of the alkaloidal salt, or saturated if less soluble, and a few drops of the reagent are used, an immediate precipitate only being noted. Before adding potassium ferrocyanide 5%, platinum chloride 5%, potassium chromate 5%, or picric acid, the solution is slightly acidified with dilute hydrochloric acid. Perchloric acid and N/10 potassium permanganate are added to the neutral solution.

It must be remembered that this scheme is intended only as a guide, and results must not be interpreted too rigidly, since uncommon alkaloids are not included, and also anomalous results might possibly occur with impure alkaloids or with any deviation from the above conditions.

| REAGENT | ALKALOIDS which give a distinct precipitate with the reagent | Other Alkaloids which give a distinct ppt., but which would be detected in previous groups |
|---|--|---|
| I. Potassium Ferrocyanide in slightly acid solution. | Apomorphine Emetine Berberine Papaverine Cinchonidine Quinidine Cinchonine Strychnine | |
| II. Perchloric Acid to neutral solution. | (i) <i>Immed. reducing</i> $KMnO_4$ Aconitine Hydrastine Veratrine (ii) <i>Not reducing</i> $KMnO_4$, <i>immed.</i> Cocaine | Berberine. Emetine. Papaverine. Strychnine. |
| III. Platinic Chloride in slightly acid solution. | Diamorphine Nicotine Quinine | Apomorphine. Berberine. Cinchonidine. Cinchonine. Emetine. Hydrastine. Papaverine. Quinidine. Strychnine. |
| IV. Potassium Chromate in slightly acid solution. | Yohimbine (If impure, yohimbine may precipitate in the potassium ferrocyanide group) | All the alkaloids previously mentioned give ppt. except Aconitine, and Nicotine. |
| V. Picric Acid in slightly acid solution. | (i) <i>Immed. reducing</i> $KMnO_4$ Codeine Morphine Ethylmorphine Narceine Gelsemine Eserine (ii) <i>Not reducing</i> $KMnO_4$, <i>immed.</i> Atropine Hyoscyamine Homatropine Sparteine Hyoscine | All the alkaloids previously mentioned give a ppt. with this reagent. |
| VI. Mayer's and Gold Chloride. | Coniine Pilocarpine Ephedrine | All the alkaloids in this table give ppt. |

COLOUR REACTIONS WITH FROEHDE'S REAGENT

A few drops of the reagent are added to a little of the dry alkaloid in a white dish, the colour being observed after a few minutes. Colorations, being due to reduction of the reagent, are also given by some non-alkaloidal substances, e.g., Salicin, Phloridzin, Colocynthin.

The following alkaloids give a distinct colour:—

| | |
|--|----------------------------|
| Apomorphine (bluish-green). | Morphine (deep red). |
| Berberine (dark greenish-brown). | Narceine (reddish-green). |
| Codeine (bluish-green). | Nicotine (red). |
| Diamorphine (red). | Papaverine (bluish-green). |
| Emetine, in presence of NaCl (green). | Quinidine (pale green). |
| Ethylmorphine (yellow, turning green). | Quinine (pale green). |
| Hydrastine (green). | Veratrine (red). |
| | Yohimbine (violet). |

Other alkaloidal reagents are the following:—

AMMONIACAL SILVER NITRATE. A mixture of equal volumes of 2% silver nitrate solution and dilute solution of ammonia.

AMMONIUM SULPHOMOLYBDATE. Froehde's Reagent. Ammonium molybdate, 1 g., in concentrated sulphuric acid, 100 ml.

ERDMANN'S REAGENT. Mix 6 drops of nitric acid (sp. gr., 1.25) with water, 100 ml., add 10 drops of this to 20 ml. of concentrated sulphuric acid.

KRAUT'S REAGENT. Dissolve 8 g. of bismuth nitrate crystals in 20 ml. of diluted nitric acid (30% w/w HNO₃), add a solution of 27.2 g. of potassium iodide in 50 ml. of water and dilute to 100 ml.

MANDELIN'S REAGENT. Sulphovanadic acid. A 1% solution of sodium vanadate in concentrated sulphuric acid.

MARMÉ'S REAGENT. Dissolve 3 g. of cadmium iodide in 18 ml. of water containing 6 g. of potassium iodide.

MERCURIC CHLORIDE SOLUTION. 1 in 20.

MERCURIC CHLORIDE-SODIUM CHLORIDE. Dissolve mercuric chloride 5 g. and sodium chloride 0.75 g. in water to 100 ml.

PLATINIC CHLORIDE. 1 in 20.

PHOSPHOTUNGSTIC ACID. Dissolve sodium tungstate, 100 g., and sodium phosphate, 70 g., in water, 500 ml., and acidify with nitric acid.

PHOSPHOMOLYBDIC ACID. Sonnenschein's Reagent. Consists of a solution of sodium phosphomolybdate in nitric acid, prepared by acidifying a warm solution (50° to 60°) of sodium phosphate with nitric acid, and adding an excess of ammonium molybdate solution. The yellow precipitate is separated, washed with water, then with nitric acid and dissolved in a hot solution of sodium carbonate (using as little as possible). The solution is evaporated to dryness and ignited at low red heat till all ammonium salts are volatilised, the residue moistened with nitric acid and again ignited. The product, consisting of sodium phosphomolybdate, is dissolved in ten times its weight of water, and nitric acid (sp. gr., 1.42) added until the precipitate at first produced redissolves.

TANNIC ACID. A solution of tannic acid, 1 g., in water, 8 ml., and alcohol, 1 ml.

WAGNER'S REAGENT. Iodine in potassium iodide. Iodine, 5 g.; potassium iodide, 10 g.; water, 100 ml. In using this reagent, e.g., in testing for complete extraction in alkaloidal assays, it should be noted that water saturated with ether and then acidified gives a precipitate of iodine on adding this reagent. The precipitate may be distinguished from that due to an alkaloid by adding water. If due to iodine, it will redissolve.

Ferro- and ferricyanides used to differentiate numerous alkaloids microscopically.—W. M. Cumming and D. G. Brown, *Pharm. J.*, ii/1925, 141.

For formulæ for preparation of Mayer's, and Dragendorff's Solution, *vide* pp. 208 and 108, Gold Chloride solution is used 1 in 20.

MICROCHEMICAL TESTS FOR ALKALOIDS.

Tentative or official tests are described in *Methods of Analysis (A.O.A.C.)*. The tests are carried out on a microscope slide using one drop of test solution and one drop of reagent, the effects produced being examined under a magnification of 100 to 150. The test solution is an approximately 1% aqueous solution of the alkaloidal salt or of the base dissolved with the aid of the minimum quantity of N/10 hydrochloric acid. The reagents are employed as 5% *w/v* aqueous solutions except in the case of the special reagents the formulæ for which are given. A table gives the results for a large number of alkaloids and closely related substances.

2. *Purine Bases*

These are weak bases reacting with only a few alkaloidal reagents, and are characterised by giving the murexide test, see Caffeine.

Caffeine, Theophylline, Theobromine and also their compounds with sodium salts such as Theobromine Sodium Salicylate. Uric Acid.

3. *Urea Compounds and Ureides*

Ureides are hydrolysed by strong potassium hydroxide, slowly in some cases, into the potassium salt of the acid and urea, the latter compound undergoing further decomposition giving potassium carbonate and evolving ammonia. (N.B.—Amides, e.g., Acetamide and Chloralamide, also yield ammonia on heating with alkali solution, but without formation of carbonate.) Note also precipitation with Millon's reagent, *v. Barbitone*, p. 533.

Test for Urea and Urethane (both readily soluble in water) and the ureides Alloxan, Allantoin, Allobarbitone, Barbitone, Hexobarbitone, Pamaquin, Phemitone, Phenobarbitone, Proponal, Soneryl, Veronal, etc.

4. *Amines*

Test for primary amines by the carbylamine reaction. Warm the substance with alkali and a little chloroform, and note any isocyanide odour.

This reaction is not given by primary amines capable of forming non-volatile salts, e.g., Aminophenols, Aminocarboxylic Acids, Aminosulphonic Acids.

If however, after heating, a sample is withdrawn on a glass rod and held in the current of air breathed out from the nose, the carbon dioxide combines with the alkali and liberates the volatile carbylamine derivative, the odour of which soon becomes noticeable.—*J. chem. Soc. Abstr.*, ii/1924, 430.

(i) *Aliphatic Primary Amines*

After solution of the substance in excess HCl and treatment with sodium nitrite these compounds yield an alcohol on heating, but they are rarely met with except as the amino-acids. Asparagine, for example, is converted into malic acid by nitrous acid.

(ii) *Aromatic Primary Amines*

These bodies form a diazonium compound with sodium nitrite and acid, which usually couples with an alkaline solution of β -naphthol forming dyes, and also gives a phenol on heating. Examine for Aniline, Benzocaine, Sodium Aminarsonate.

The following give reactions for a primary amine after hydrolysis:—
Acetanilide, Phenacetin.

(iii) *Secondary Amines*

Treatment with nitrous acid forms a nitroso compound which can be identified by Liebermann's reaction.

Methylacetanilide gives the secondary amine, methylaniline, after hydrolysis. The following compounds give colours with nitrous acid:—

| | | | |
|-------------|----------------|------------|---------------|
| Adrenaline | red colour. | Orthocaine | yellow colour |
| Amidopyrine | violet colour. | Phenazone | green colour. |

5. *Inorganic Matter Present*

Important compounds are those of Silver, e.g., Silver Proteinates, Colloidal Silver. The presence of inorganic matter in compounds of this group may denote a metallic cyanide, ferro- or ferricyanide.

Mercury Cyanide and Oxycyanide; Mersaly; Sodium compounds, Suebll, Barbiturates, etc.

6. Amino-Acids

These are neutral compounds usually soluble in water and insoluble in alcohol and ether.

Common substances are:—

Hippuric Acid.

Hydrolysed by HCl to benzoic acid and glycocoll.

Glycocoll (aminoacetic acid).

Gives deep blue colour with CuSO_4 due to copper glycocoll. FeCl_3 gives intense red colour discharged by acids.

Anthranilic Acid.

Heated with calcium oxide yields aniline. Treatment with nitrous acid and warming gives salicylic acid.

Betaine

Usually occurs as the hydrochloride which gives a very acid solution in water. Fusion with KOH gives trimethylamine.

Forms a periodide on adding a solution of iodine.

7. Esters of Nitrous and Nitric Acids

Amyl and Ethyl Nitrites have characteristic effect on inhaling. (See Vol. I, p. 160.)

Glyceryl Trinitrate, Mannityl Hexanitrate, and Erythrityl Tetranitrate are readily hydrolysed giving a nitrate. Being very explosive they usually occur only in solution or massed with an inert substance.

8. Nitro-compounds

Reduction in acid solution gives primary amines which can be identified as described above. Usually poisonous and not used medicinally.

GROUP IV. Compounds containing Sulphur. (Halogens, Nitrogen and Phosphorus being absent).

Phenolsulphonates of Zinc and Sodium, Sulphorcinates, Sulphonal, Thioresorcinol, Mesulphen.

GROUP V. Compounds containing Nitrogen and Sulphur (and free from Halogens and Phosphorus).

A solution of the substance should be tested for sulphate, and if present the organic base, which is probably alkaloidal, should be examined as described in Group III.

Other substances are:—Albumin Tannate, Amphetamine Sulphate, Bile Acids and Salts, Glycogen, Indigo Carmine, Neoarsphenamine, Potassium Hydroxyquinoline Sulphate, Proflavine, Saccharin, Sulphanilamide, Sulphapyridine, Sulphathiazole, Suramin, Thiosinamine.

GROUP VI. Compounds containing Nitrogen and Halogens (and free from Sulphur and Phosphorus).

A solution should be tested for ionised halogen by means of silver nitrate, which indicates the presence of a salt of an organic base. The latter if alkaloidal is described in Group III.

CHLORINE COMPOUNDS

Acriflavine, Arsphenamine, Betaine Hydrochloride, Chloralamide, Chloramine-T, Dichloramine-T, Fuchsine, Malachite Green, Mepacrine Hydrochloride, Carbachol.

Cocaine Substitutes, e.g., Amydracaine, Amylocaine, Procaine, etc., are mentioned in Group III.

BROMINE COMPOUNDS

Bromo-valerianyl-urea, Carbromal.

IODINE COMPOUNDS

Tetraiodopyrrol, Iodoxyl Diodone.

GROUP VII. Compounds containing Halogens, Nitrogen and Sulphur
(Phosphorus absent).

Methylene Blue, Thiosinamine Ethyl Iodide, Aneurine Hydrochloride, Chiniofon, Mepacrine Methanesulphonate.

GROUP VIII. Compounds containing Phosphorus.

Glycerophosphoric Acid and Salts, Alkaloidal Phosphates
Nuclein, Nucleinic Acid, Lecithin.

**Physical Constants of Value for the Recognition
of Organic Substances and used in the Table of
Corroborative Tests on page 520 et seq.**

Melting-Point. Substances which are readily reduced to a powder are dried at a temperature considerably below the melting-point. The melting-point is determined by the capillary tube method, using thermometers and apparatus which comply with specifications given in an appendix to the *B.P.* The thermometer and capillary tube are immersed in a suitable liquid, previously heated to a temperature 10° below the melting-point and the rate of rise of temperature is then carefully regulated to 2° per minute.

Boiling-Point. The boiling-point of a substance is defined in the *B.P.* as the range of temperature within which the whole or a specified portion of the substance distils. The determination is carried out on 100 ml. of the substance in a standard apparatus which is described in an appendix to the *B.P.* The heat is regulated to obtain a rate of distillation of 4 to 6 mls. per minute for liquids boiling below 150° and 2 to 4 mls. per minute for liquids boiling above 150° . The temperature is taken when the first drop of distillate falls from the condenser and subsequent readings are taken after specified amounts have distilled. Correction is made for the barometric pressure which is itself corrected for index error, temperature and gravity. For every 10 mm. above or below 760 mm. pressure, 0.4° is subtracted or added to the observed readings for most liquids. In the case of acetone the correction for 10 mm. is 0.38° and that for chloroform is 0.42° .

Refractive Index. The refractive index of a substance is determined in a refractometer at the specified temperature.

Optical Rotation. The optical rotation is determined in a polarimeter using a 1 dcm. tube containing the substance (if a liquid) or a solution of the substance of specified strength. The determination is made at 20° , sodium light being used. The specific rotation is calculated from the following formula:—

Specific Rotation = $\frac{\alpha \times 100}{l \times c}$, where α = observed rotation, l = length of tube in dcm., and c = concentration in g. per 100 ml. of solution examined.

Viscosity. The viscosity of a liquid is determined in a standard apparatus, specifications for which are given in an appendix to *B.P. Add. IV*. The determination is carried out at a specified temperature.

Specific Gravity. The specific gravity of liquids is determined at 15.5° unless otherwise stated.

CORROBORATIVE

The following table gives the physical constants and
It will be found useful when confirming results

TESTS

characteristic reactions of many medicinal compounds.
obtained by the preceding general scheme of analysis.

| No. | SPECIAL TESTS |
|-----|---|
| 1 | Shaken with conc. sodium bisulphite solution gives crystalline addition-product, $\text{CH}_3\text{CH}(\text{OH})\cdot\text{SO}_3\text{Na}$, decomposed by acid or alkali. Combines with phenylhydrazine forming ethyldenenphenylhydrazone. Combines with NH_3 forming additive compound. |
| 2 | Hydrolysed by acid or alkali solution to aniline and acetic acid (or acetate), 0.1 g. boiled with 2 ml. of hydrochloric acid, then mixed with 3 ml. of phenol solution (1 in 20) and 5 ml. of saturated chlorinated lime solution, turns brownish-red changing to blue on adding ammonia (Indophenol Test). Heated with boric acid over a naked flame, gives yellow residue and sweet odour. Phenacetin gives yellow, phenazone a pink, and naphthalene an orange. 0.001 g. in 5 ml. water heated with NaOH and few drops chloroform gives phenyl isocyanide odour. |
| 3 | Shaking with ethyl alcohol and sulphuric acid gives odour of ethyl acetate. |
| 4 | A solution of 0.2 g. in 0.4 ml. of sodium hydroxide solution, diluted to 2 ml. with water, gives no ppt. in the cold with magnesium ammonio-sulphate solution but a white ppt. is produced on boiling. |
| 5 | Heated with H_2SO_4 conc. acetic acid is evolved with an odour of naphthalene. |
| 6 | Oxidation with potassium dichromate and sulphuric acid gives acetic and formic acids. Combines with chloroform in presence of alkali hydroxide to give acetone-chloroform (colourless insoluble crystals, m.p. 96°). 0.00001 ml. in 10 ml. of water warmed to 70° , 1 g. of potassium hydroxide added and then 10 drops of salicylaldehyde gives a purplish-red ring. |
| 7 | 0.01 g. in 5 ml. water with hydroxylamine hydrochlor. forms acetoxime, $\text{C}_6\text{H}_5\text{C}(\text{N}(\text{OH})\cdot\text{CH}_3$ (white ppt., m.p. 59°). This by boiling with dilute sulphuric acid in glacial acetic acid is converted into acetanilide (Beckmann's reaction), and then aniline (odour) and acetic acid. |
| 8 | Hydrolysed on warming with alkali into alkali salicylate and acetyl- <i>p</i> -aminophenol, the solution becoming blue. |
| 9 | Unstable in solution and readily hydrolysed by alkalis to choline. Aurichloride has m.p. 166° to 168° ; platinichloride has m.p. 256° to 257° . |
| 10 | Solution has bitter taste and readily hydrolysed by alkalis to methylcholine. |
| 11 | The nearly neutralised solution gives a deep red colour with ferric chloride, the liquid giving a reddish-brown ppt. on boiling, and a yellow colour on the addition of hydrochloric acid. |
| 12 | When boiled with alkali and the solution acidified, a white ppt. of salicylic acid is produced. |

| No. | SPECIAL TESTS |
|-----|---|
| 13 | Turns gelatinous and soapy on boiling with water. 0.00001 g. in 5 ml. water with 15 ml. sulphuric acid, cooled and a few drops of syrup added gives a purple in a few minutes. |
| 14 | The aqueous solution gives a red colour with ferric chloride solution. When boiled with copper oxide, filtered while hot and the solution cooled, bright blue needles of the copper salt are obtained. When treated with benzoyl chloride, hippuric acid (m.p. 187°) is obtained. |
| 15 | The aqueous solution decolorises solution of 2:6-dichlorophenol-indophenol, reduces Fehling's solution giving a yellowish ppt., and immediately reduces potassium permanganate solution. |
| 16 | 0.001 g. in 0.5 ml. water gives light buff ppt. with 1 drop of ferric chloride solution. 0.001 g. warmed with 3 drops of 25% formic acid and the solution neutralised with lime water, evaporated to dryness and the residue heated in ignition tube gives benzaldehyde odour. |
| 17 | 0.005 g. dissolved in 5 ml. water and a few drops hypophosphorous acid added gives a cacodyl odour in a few seconds. |
| 18 | Gives sublimate of anhydride, m.p. 217°, on heating. Neutralised solutions give a yellowish-brown ppt. with ferric chloride and a light blue ppt. with copper sulphate. |
| 19 | 0.0025 g. oxidised with potassium permanganate gives benzaldehyde odour. Can be reduced by sodium amalgam to hydrocinnamic acid (β -phenylpropionic acid). Detected in presence of benzoic acid by suspending in 5% uranium acetate solution and exposing to sunlight—in a few minutes the odour of benzaldehyde is evolved and a brown ppt. forms. |
| 20 | DENIGÉ'S TEST: Add mercuric sulphate solution to the citrate solution. On warming, this solution decolorises potassium permanganate, giving white ppt.; visible 0.001 g. in 5 ml. water. Tartaric acid does not react. A solution is boiled with a little potassium dichromate, and, after cooling, acetic acid and sodium nitroprusside added and then ammonia to form a layer. Acetone from the citric acid gives a violet-red colour at the surface of contact. |
| 21 | Melted with potassium hydroxide gives salicylate and acetate. Aqueous solutions of alkaline coumarates are fluorescent. |
| 22 | Gives a ppt. of mercurous chloride when warmed with mercuric chloride solution, and when warmed to 40° with mercuric oxide the filtrate gives a grey ppt. of mercury on boiling. Heated with conc. sulphuric acid, CO is evolved without charring. |
| 23 | Aqueous solution gives white ppt. with potassium antimonyltartrate solution. 0.000125 g. in 5 ml. water on adding lime water gives pink colour; 0.00025 g. gives purple; 0.0005 g. gives blue-grey ppt. 0.005 g. in 5 ml. water turns brown with sodium nitrite alone. Gives no ppt. with gelatin solution (<i>cf.</i> tannic acid). |
| 24 | 0.001 g. in 5 ml. water boiled 3 minutes with hydrochloric acid gives phosphoric acid and glycerin. |

| 25 | Acid Hippuric | C,H,O,N | 187 | — | — | Very slight | 30 |
| 26 | Acid Lactic | C,H,O | — | — | About 1·21 | Miscible | Miscible |
| 27 | Acid Malic | C,H,O | About 100 | — | — | 1 | 1·5 |
| 28 | Acid Mandelic | C,H,O | 118-119 | — | — | 8 | 2 |
| 29 | Acid Meconic | C,H,O | — | — | — | Slight | 48 |
| 30 | Acid Nicotinic | C,H,O,N | 234-237 | — | — | 75 | Readily soluble |
| 31 | Acid Nucleinic | C,H,O,N,P | — | — | — | Almost insoluble | Insoluble |
| 32 | Acid Oleic | C,H,O | — | 288 (15 mm.) | About 0·898 | Insoluble | Readily |
| 33 | Acid Oxalic | C,H,O | 98-100 | — | — | 9 | 8 |
| 34 | Acid Ricinoleic | C,H,O | Solidifies at about 4 | — | 0·945-0·948 | Insoluble | Soluble |
| 35 | Acid Salicylic | C,H,O | 158-159 | — | — | 500 | 3·5 |
| 36 | Acid Stearic | C,H,O | 50-55 (69·3 when pure) | — | — | Insoluble | About 25 |
| 37 | Acid Succinic | C,H,O | Not below 185 | — | — | 20 | 9 |
| 38 | Acid Sulphanilic | C,H,O,N,S | Decomposes at 280-300 | — | — | About 160 | Insoluble |

| No. | SPECIAL TESTS |
|-----|---|
| 25 | Boil 0.01 g. a few minutes with 1 ml. sodium hydroxide solution and neutralise with hydrochloric acid. Half this solution gives buff ppt. with ferric chloride (benzoate). Acidify the other, evaporate to dryness, extract the glycooll with ethyl acetate. This dissolves freshly pptd. copper carbonate giving a deep blue solution. Copper benzoate, if present, does not interfere and if necessary benzoic acid can be removed with ether in which glycooll is insoluble. |
| 26 | 1 g. warmed with 0.1 g. potassium permanganate evolves the odour of acetaldehyde. |
| 27 | Treated with potash and bromine, bromoform is formed. Heat 0.05 g. on a water-bath with 1 ml. of conc. sulphuric acid and a trace of β -naphthol; an intense yellow colour is produced. |
| 28 | Benzaldehyde is evolved on heating to 200°. |
| 29 | An aqueous solution with ferric chloride gives a red colour not discharged by hydrochloric acid or mercuric chloride (distinction from thiocyanate). |
| 30 | Pyridine evolved when heated with soda-lime. 6 ml. cyanogen bromide and 1 ml. 2.5% aqueous aniline to 2 ml. 0.1% solution in water gives golden-yellow colour; stronger solution will give red ppt. Yellow colour with excess of NaOH solution is due to presence of pyridyl-nitropyrazole. |
| 31 | Decomposes on boiling with dilute sulphuric acid; product yields phosphoric acid, carbohydrates and xanthine bases (xanthine, guanine, etc.). |
| 32 | Characteristic odour. Solidifies at 4°, melting again at about 14°. Gives an acid reaction only in alcoholic solution. To 1 ml. of oleic acid and 3 ml. of saturated aqueous solution of sodium nitrite add 1 ml. of sulphuric acid; on standing for a few hours the solid stereoisomeride elaidic acid is formed. |
| 33 | A neutralised solution gives a ppt. with calcium chloride insoluble in acetic acid but soluble in hydrochloric acid. The ppt. mixed with dilute sulphuric acid decolorises potassium permanganate on warming. |
| 34 | Commercial acid has low acid value—not less than 120. Yields ricinelaidic acid with H_2SO_4 and saturated sodium nitrite solution. |
| 35 | Aqueous or alcoholic solutions give a purple colour with 1 drop of ferric chloride solution, just visible with 0.0025 mg. in 1 ml. |
| 36 | Acid value 200 to 210. |
| 37 | Forms fluorescein dyes when heated with resorcin and sulphuric acid. |
| 38 | Neutral solution of salt gives brown ppt. with ferric chloride; when ppt. is washed, dissolved in ammonia and the solution filtered, the filtrate gives a ppt. with barium chloride and equal volume of alcohol. |

| 51 | Alcohol Tri-bromoethyl | C ₂ H ₃ OBr | 79-81 | — | — | 35 at 25° | Soluble |

| No. | SPECIAL TESTS |
|-----|---|
| 39 | Gives ppt. with gelatin, lead nitrate solution (with 0.0001 g.), bismuth nitrate solution (with 0.0001 g.), and ammoniacal copper solution (distinctions from gallic acid). 0.0001 g. gives blue with ferric chloride. Is hydrolysed into gallic acid and dextrose by boiling with dilute sulphuric acid. Gives brown with sodium nitrite solution. |
| 40 | To a neutral solution add silver nitrate; white silver tartrate is pptd. On just dissolving in dilute ammonia and warming, a silver mirror is obtained if test-tube is clean. To aqueous solution add 1 drop ferrous sulphate, 3 drops hydrogen peroxide and excess sodium hydroxide; a deep violet colour is produced. |
| 41 | When boiled with water and sodium hydroxide solution, chloroform is produced. |
| 42 | Has a characteristic, unpleasant odour. Fused calcium chloride separates the acid from its aqueous solution. Zn and Ag salts are insoluble. |
| 43 | 0.001 g. warmed with 4 drops sulphuric acid (sp. gr. 1.75) and a crystal of resorcinol added, the liquid becomes reddish-violet in about 20 minutes. 0.000001 g. produces tingling and numbing on the tongue. 0.0001 g. with dilute acetic acid gives red ppt. with potassium permanganate, not changed with bromine water. |
| 44 | Dilute solution is yellow, strong solutions red with deep green fluorescence; gives hydrogen chloride on heating with sulphuric acid (distinction from proflavine). Bulky yellow ppt. with 10% solution of sodium salicylate. |
| 45 | Sodium nitrite alone gives red colour. Reduces silver nitrate solution. Faintly acid solution with 0.25% ferric chloride solution gives emerald-green colour; on gradual addition of sodium bicarbonate solution colour changes through blue to red. |
| 46 | Yields dextrose and æsculetin on hydrolysis and then reduces Fehling's. Gives blood-red colour when treated with nitric acid and then excess of ammonia. Gives blue fluorescence in alkaline solution. Treated with sulphuric acid and then solution of sodium hypochlorite it gives a violet colour. |
| 47 | Decomposed by aqueous alkali hydroxides and carbonates. |
| 48 | Crystalline and greasy to the touch. Iodine value, not more than 20 for commercial alcohol. |
| 49 | Heated with sulphuric acid it gives propylene (characteristic odour). Oxidised with 4 vols. of 10% potassium dichromate and 1 vol. of sulphuric acid, acetone is evolved. |
| 50 | Oxidised by hot copper wire, coated with oxide, to formaldehyde. |
| 51 | Unstable; after hydrolysis with warm NaOH solution, gives reactions for bromides. Usually met with in amylene hydrate solution as avertin. |

| No. | SPECIAL TESTS |
|-----|--|
| 52 | Conc. furfural solution to which a little hydrochloric acid is added gives a violet colour with an aqueous solution. Mercuric nitrate (not chloride) gives a ppt. as with urea. |
| 53 | 0.1 g. in 1 ml. sulphuric acid gives yellow solution changing slowly to dark red. 0.001 g. heated with sodium hydroxide solution and acidified with sulphuric acid gives carbon dioxide with acetic odour. Saturated aqueous solution gives white ppt. with Millon's reagent, soluble in excess. |
| 54 | Dissolves in ammonia and caustic alkalis, the yellow solution rapidly turning red with green fluorescence. Ferric chloride added to alcoholic solution gives brown-green colour. One drop of copper sulphate solution added to 0.00005 g. in 5 ml. water gives yellow colour changed to red by 0.5 ml. saturated sodium chloride and to violet by 1 ml. 90% alcohol. |
| 55 | Surface anæsthetic, formerly known as Decicain. |
| 56 | Silver nitrate gives violet colour followed by ppt. of metallic silver. Ferric chloride gives bluish-violet. Sodium nitrite and hydrochloric acid give violet. |
| 57 | Very hygroscopic. Gives ammonia and benzaldehyde when heated. |
| 58 | Volatilises readily at ordinary temperatures. The 10% solution in NaOH with benzoyl chloride gives benzoyl derivative which melts at 134°-135°. |
| 59 | Gives reaction of sulphates and can be identified by m.p. of the benzoyl derivative of base (<i>see under</i> Amphetamine). |
| 60 | Behaves similarly to cocaine, <i>q.v.</i> Can be distinguished by fact that 4% solution does not precipitate with platinic chloride in presence of hydrochloric acid. |
| 61 | Characteristic odour—produces flushing of face on inhalation. |
| 62 | Yields amyl alcohol and valeric acid on hydrolysis. |
| 63 | Has a pungent taste, and an odour resembling camphor and peppermint. It solidifies to crystals on cooling to a low temperature. Oxidation with chromic acid gives acetone and acetic acid. |
| 64 | Isomeric with Pentobarbitone Soluble; contains isoamyl groups instead of methylbutyl. Gives general reactions of malonylureas; free acid melts 153°-155°. |

|-----|---|
| 65 | Distinguished from cocaine by giving no ppt. with potassium permanganate but decolorising it slowly. Aqueous solution gives ppt. on addition of iodine solution (distinction from orthocaine) and with Mayer's reagent (distinction from orthocaine and benzocaine). |
| 66 | An androgenic hormone in male urine; usually met with in oily solution in ampoules. |
| 67 | The picrate melts at 206° to 208°. 0.01 g. in 10 ml. of 2N NaOH and 10 ml. of potassium ferricyanide solution, shaken for 2 minutes with butyl alcohol, gives intense blue fluorescence in separated alcoholic layer (thiocrome reaction). Trace in 0.3 ml. of mixture of 7 vols. of N/1000 HCl and 3 vols. of alcohol, with 1 drop of formaldehyde solution and a solution consisting of 1.25 ml. of mixture of equal vols. of N/1 NaOH and 5.76% sodium bicarbonate solution and 0.5 ml. of diazobenzenesulphonic acid solution, gives pink colour on standing which forms pink layer when shaken with butyl alcohol and allowed to separate. |
| 68 | To neutral or slightly alkaline solution add sodium hypochlorite or chlorinated lime solution—purple-violet, even in 1 in 26,000, changing to dirty red. Avoid excess of reagent. When this change has occurred add ammoniacal phenol solution; return of blue colour even in 1 in 66,000. Aqueous chromic acid solution, according to concentration, gives green, blue or almost black. |
| 69 | Easily soluble in caustic alkalis and ammonia, giving yellowish solution gradually changing to green or blue owing to formation of alizarin. |
| 70 | A green liquid with characteristic odour and taste. |
| 71 | Occurs usually as a yellowish or greenish-grey hygroscopic powder. Gives a characteristic blood-red colour with nitric acid. |
| 72 | On adding ammonium persulphate and sodium bicarbonate to aqueous solution and shaking with chloroform the latter becomes a red or violet. Detects 1 in 100,000. Acquires a green tint when exposed to light and air, and dissolves in nitric acid with purple colour. Dilute aqueous solution with sodium bicarbonate solution gives ppt. which is white at first, becoming green. Ppt. dissolves in alcohol (green), chloroform (blue) and ether (purple). |
| 73 | Hydrolysed by dilute sulphuric acid into dextrose and hydroquinone. Diazo Test—yellow with sodium nitrite solution and hydrochloric acid turning red with sodium hydroxide. |
| 74 | Aqueous solution gives with mercuric chloride solution a white ppt. soluble in excess, the solution depositing colourless crystals on standing a few hours. Sulphuric and selenious acids give a bright yellow colour (distinction from pelletierine). |
| 75 | 1 ml. of 1% solution with 1 drop of 5% sodium nitrite gives orange colour. 0.5 ml. of resulting solution with 1 ml. 2% β -naphthol in 2N sodium hydroxide gives a clear wine-red solution. |

|-----|---|
| 76 | In alkaline solution is laevorotatory; in acid, dextro. Copper hydroxide is dissolved on boiling, forming a blue solution, depositing on cooling asparagin-copper ($C_4H_7O_2N_2$) ₂ Cu. Insoluble in ether. |
| 77 | 0.001 g. warmed with 2 ml. mercuric chloride in 50% alcohol causes deposition of mercuric oxide (with some mercurous oxide). Dilates the pupil even 1 in 130,000. 0.01 mg. responds to VITALI'S REACTION: Evaporate a trace of atropine (or a salt) in a porcelain dish with a few drops of fuming nitric acid; a yellow residue is produced which on moistening with alcoholic potassium hydroxide (1 in 10) produces a violet colour. Strychnine does the same on applying 4% potash, but the colour is evanescent. Veratrine gives red-violet or orange-red. |
| 78 | Yields reactions of atropine and on saponification with alc. KOH produces potassium nitrate. |
| 79 | Gives aurichloride, m.p. 137° to 139°. |
| 80 | A saturated solution acidified with nitric acid gives ppt. with Millon's reagent, soluble in excess. When heated with sodium hydroxide (solid or conc. solution), ammonia is evolved. |
| 81 | Aqueous solution gives ppt. of barbitone on acidifying. |
| 82 | Occurs in brown translucent scales and contains about 30% of beberine with other alkaloids. |
| 83 | Benzamine lactate and benzamine hydrochloride—0.1 g. in 1 ml. sulphuric acid maintained at 100° for 5 minutes and cautiously diluted with 2 ml. water gives aromatic odour and on cooling deposits crystals of benzoic acid. |
| 84 | 0.05 g. with 0.25 g. calomel does not blacken when moistened with water (distinction from cocaine hydrochloride). 5 ml. of 1% solution gives no permanent ppt. with 5 ml. mercuric chloride solution or with 5 ml. potassium iodide solution (distinction from cocaine and alpha-caine respectively). 4% solution of the hydrochloride gives a slight golden-brown ppt. with platinic chloride, dissolving in hydrochloric acid and separating again in crystals on standing. |
| 85 | To distinguish from petroleum benzene note solubility in alcohol; benzene is soluble with half volume of alcohol 90%, but petroleum benzene requires 5 to 6 volumes (using petrol, more). Warm 1 ml. with 5 to 10 ml. of mixture of nitric and sulphuric acids (2 : 1); benzene gives red vapour and yellow nitro-compounds; on diluting with water an odour of benzaldehyde is evolved. Petroleum benzene is practically unaffected. |
| 86 | 1 ml. 1% aqueous solution with trace of hydrochloric acid and 1 to 2 drops of sodium nitrite solution followed by 1 to 2 drops of β -naphthol in sodium hydroxide solution gives a deep red colour and, on standing, scarlet ppt. |
| 87 | Decomposes into benzyl alcohol and sodium benzoate on boiling with sodium hydroxide. |

| No. | SPECIAL TESTS |
|-----|---|
| 88 | Hydrolysis with alkali yields benzyl alcohol and <i>p</i> -hydroxybenzoic acid. A trace boiled with water gives reddish-violet solution with 1 drop of ferric chloride changing to brown on adding further 2 drops mercuric nitrate to boiling sol. gives ppt. and red supernatant liquid. |
| 89 | Hydrolysed to benzyl alcohol and sodium succinate on boiling with sodium hydroxide. |
| 90 | With conc. sulphuric acid gives yellow colour which on warming gradually darkens through brownish-red to dark red; conc. nitric acid gives pale yellow colour; ammonium molybdate and conc. sulphuric acid gives a violet, changing through brown to a permanent blue. |
| 91 | To 5 ml. of 1% aqueous solution add 2 drops sodium hydroxide solution; the liquid acquires an orange red colour but gives no ppt. On adding 4 drops acetone, it becomes turbid and gives yellow ppt. on standing. |
| 92 | Gold salt melts at 224°. Has a strongly acid reaction and taste. Fusion with potassium hydroxide gives trimethylamine. |
| 93 | Gives bluish fluorescence on adding 1 ml. solution of ammonia to 10 ml. saturated aqueous solution. |
| 94 | Soluble in ammonia and alkali citrates. Gives citrate and bismuth reactions. |
| 95 | Identify bismuth and salicylic acid—the latter by shaking powder with ether and dilute sulphuric acid; on shaking ethereal layer with water containing trace of ferric chloride, a violet colour is produced. |
| 96 | Gives reactions of bismuth, sodium and after removal of bismuth, of tartrate. |
| 97 | Soluble in hot mineral acids and in alkali hydroxide giving a yellow solution rapidly changing to deep red. When suspended in water and the bismuth removed by hydrogen sulphide, the filtrate gives a bluish black colour with ferric chloride. |
| 98 | Boiled with sodium hydroxide solution and the liquid acidified, a ppt. of tribromophenol is produced which when washed and dried has m.p. 90° to 95°. |
| 99 | A 1 in 1000 solution acquires a brownish-red coloration with excess of sodium hydroxide solution and a blue coloration with concentrated sulphuric acid. |
| 100 | Decomposes at 100° to 110° into bromal and water. |
| 101 | Has odour resembling chloroform, from which it is easily distinguished by sp. gr. and b.p. |
| 102 | Odour like bromal on heating. Dissolves in caustic alkali solution and is pptd. by acids. After heating with sodium hydroxide and acidifying the residue with sulphuric acid, carbon dioxide is liberated with valerianic odour. Millon's reagent gives ppt. (<i>cf.</i> barbitone). Nessler's reagent with saturated solution gives only slight colour and ppt. (<i>cf.</i> carbromal), but after fusing with potassium hydroxide and dissolving in water there is the usual effect. |

| 116 | Calcium Levulinate | C,H,O,Ca | — | — | — | 2.5 | Insoluble |

| No. | SPECIAL TESTS |
|-----|---|
| 103 | Yields normal reactions of alkaloids and red colour with conc. HNO_3 . No violet colour with sulphuric acid and potassium dichromate (distinction from strychnine). |
| 104 | Nitric acid converts it into trichlorobutyric acid, m.p. 44° . |
| 105 | Dissolves in aqueous alkali hydroxides; heated with conc. NaOH , ammonia is evolved. |
| 106 | On evaporating 0.0001 g. to dryness with bromine water a reddish-brown spot is obtained, which turns violet-red with ammonia vapour (murexide reaction). Aqueous solution with N/10 iodine gives no ppt. unless acidified with hydrochloric acid. |
| 107 | The aqueous solution is acid owing to hydrolysis. All the citric acid present can be titrated with caustic soda using phenolphthalein as indicator. Murexide test as above. |
| 108 | Gives sublimate of caffeine when heated in dry tube. Gives reactions of caffeine and sodium benzoate. Caffeine can be extracted with chloroform from alkaline solution. |
| 109 | Gives reactions of caffeine and sodium iodide. Caffeine sublimes on heating. |
| 110 | Gives reactions of caffeine and sodium salicylate. Caffeine can be estimated by extraction with chloroform from alkaline solution. |
| 111 | The 3:5-dinitrobenzoate has m.p. 147° to 149° . |
| 112 | Hydrochloric acid ppts. aspirin; filtrate gives reactions for calcium. After hydrolysis, gives reactions for salicylic acid. |
| 113 | 2% aqueous solution gives a yellow colour with 1 drop of ferric chloride solution. The aqueous solution gives when heated for 30 minutes on a water-bath with acetic acid and phenylhydrazine and cooled, white crystals of gluconic acid phenylhydrazide which, when recrystallised from hot aqueous solution and filtered through decolorising charcoal, have a m.p. of 200° to 202° (decomp.). |
| 114 | Identify calcium and phosphate after hydrolysis with acid. |
| 115 | Acidify a 1 in 20 solution with sulphuric acid, add potassium permanganate and heat—the odour of acetaldehyde is developed. |
| 116 | Heating with acetic acid and phenylhydrazine on water-bath gives characteristic phenylhydrazide. Decolorises KMnO_4 and gives reactions for calcium. |

|-----|--|
| 117 | To a suspension of a small quantity in 10 ml. of water add 5 ml. of hydrochloric acid and 0.1 g. of resorcinol in 5 ml. of water; shake and heat in a boiling water-bath for 5 minutes. A pink to red colour is produced. The test can be used to detect the compound in cream, using 10 ml. |
| 118 | Gives reactions of calcium and sodium. On warming with potassium permanganate gives acetaldehyde. |
| 119 | Characteristic odour. |
| 120 | Alcoholic potassium hydroxide has no action, but silver oxide in presence of chloroform decomposes it. Heated with 4 times its quantity of nitric acid on sand-bath forms camphoric acid and bromonitro-camphor—rhombic prisms almost insoluble in alcohol, m.p. 105°. |
| 121 | Boiled with soda and potash forms cantharidates. An exceedingly minute quantity of cantharidin will produce a blister. |
| 122 | Hydrosopic with fishy odour. Solution gives reaction for chlorides. Heated with NaOH sol. ammonia is evolved and then trimethylamine. Auric chloride cpd. after drying at 100°, melts at 183° to 184°. Cream-coloured ppt. with potassio-mercuric iodide. |
| 123 | The vapour of volatile halogen compounds imparts a green tinge to a colourless flame. |
| 124 | Sulphuric acid gives hydrogen bromide on warming. Sulphuric acid with manganese dioxide gives bromine. Heated with dilute sodium hydroxide solution, ammonia is evolved and sodium bromide formed. Does not give ppt. with Millon's reagent after acidifying (<i>cf.</i> barbitone). Saturated aqueous solution gives yellow with Nessler's reagent and then orange ppt. (Allobarbitone, barbitone and propional do not react unless fused with potassium hydroxide previously; bromoisovalerylurea and phenobarbitone give only a faint colour.) |
| 125 | Light yellow pdr. Saturated solution in H ₂ O with HCl changes colour from orange to yellow and produces yel. xtal. ppt. 1% solution gives olive-green with ferric chloride and white ppt. with copper sulphate. Nitrous acid liberates iodine. Contains nearly 30% iodine and about 20% NaHCO ₃ . |
| 126 | Water slightly warm decomposes it. Caustic alkalis decompose it into chloroform, ammonia and alkali formate. Dilute acids have no action. |
| 127 | Mixed with sodium hydroxide solution chloroform is produced. Compounds containing the group CX ₃ (X=Cl, Br, or I) on heating with 20% sodium hydroxide solution and pyridine give a red colour which passes into pyridine layer. Reaction detects less than 0.005 mg. of chloral hydrate or chloroform. |
| 128 | On ignition decomposition occurs suddenly, sodium sulphate being produced. Warmed with sodium hydroxide and aniline gives phenyl isocyanide odour. Liberates iodine from potassium iodide solution. Does not liberate bromine from neutral sodium bromide solution and gives white ppt. with mercuric chloride solution (distinction from dichloramine). |

|-----|---|
| 129 | Gives phenyl isocyanide odour on warming with aniline and sodium hydroxide solution. Iodoform is produced on shaking with iodine and dilute sodium hydroxide solution. |
| 130 | Violet with ferric chloride; gives reactions for chlorides after fusion with sodium carbonate. |
| 131 | Gives phenyl isocyanide odour on warming with sodium hydroxide and a trace of aniline. |
| 132 | After heating with anhydrous sodium carbonate gives reactions for chlorides. No violet colour with FeCl_3 (distinction from chlorocresol). |
| 133 | The white crystalline compound obtained from wool-fat by saponification with alc. KOH. |
| 134 | Mix a trace with 1 drop of fuming nitric acid and add 1 drop of dilute ammonia solution; an evanescent violet coloration is produced. When shaken with dilute ammonia solution mixed with twice its volume of water and the solution filtered, the filtrate slowly acquires a pink colour. |
| 135 | Gives neither thalleioquin test nor the potassium ferricyanide modification (<i>cf.</i> Cinchonine). Soluble in large amounts of ether. Sodium potassium tartrate added to neutral solution of a salt gives white precipitate. |
| 136 | Gives reactions of cinchonidine and sulphate. |
| 137 | Only slightly soluble in ether (1 in 370). Few characteristic reactions. Not pptd. by sodium bicarbonate in presence of tartaric acid (quinine and cinchonidine are). Does not give thalleioquin test nor red colour with potassium ferricyanide and ammonia on addition of these to acetic acid solution after treating with bromine (distinction from quinine and quinidine). Not rendered fluorescent by very dilute sulphuric acid. |
| 138 | Gives reactions of cinchonine and hydrochloride. |
| 139 | Saturated solution in hot hydrochloric acid gives brown crystalline ppt. with platonic chloride solution. Ammoniacal solution evaporated to small bulk and diluted with water gives a white ppt. with silver nitrate, a yellow ppt. with lead acetate and a green ppt. with copper sulphate. |
| 140 | Oxidised by potassium permanganate and acid into benzaldehyde and benzoic acid. |

| No. | SPECIAL TESTS |
|-----|---|
| 141 | <i>See Cocaine Hydrochloride.</i> |
| 142 | Addition of 1 to 2 drops chromic acid solution to 1% cocaine gives a yellow ppt. re-dissolved on shaking; with more chromic acid ppt. is permanent. |
| 143 | Does not reduce iodic acid (distinction from morphine). No blue colour with ferricyanide and ferric chloride (distinction from morphine). 0.001 g. warmed with 1 ml. sulphuric acid and 2 drops ferric chloride solution gives deep blue colour. Greenish-blue with Froehde's reagent. |
| 144 | Gives reactions of codeine and phosphate. |
| 145 | Only slightly soluble in ether or benzene. Practically insoluble in light petroleum. Sulphuric acid with a trace of nitric acid added gives yellowish-green, changing through blue-violet and wine-red to yellow. Chlorine water added to the aqueous solution gives yellow ppt. soluble in ammonia forming an orange coloured solution. Sodium nitrite and hydrochloric acid give dirty brown. |
| 146 | Gives reactions of colchicine and salicylic acid. |
| 147 | A substance having a black or metallic appearance and containing about 90% silver. |
| 148 | With conc. sulphuric acid gives a blood-red colour turning green. This liquid alkaloid is distinguished from nicotine by giving no ppt. with platinic chloride, and a deep red colour with alkaline solution of phenolphthalein. |
| 149 | 0.3 g. dissolved in 5 to 15 ml. water and N/10 iodine solution added gives brown ppt. which dried over sulphuric acid melts at 142° to 144°. Cotarnine dissolves in conc. nitric acid with formation of a red solution and oxalic acid. |
| 150 | Decompose salt and identify the alkaloid and phthalic acid. |
| 151 | Has a characteristic fragrant odour and sublimes at 100°. Dissolves slowly in hot sodium hydroxide solution with a slight green colour, excess of acid reprecipitating coumarin. Saturated aqueous solution with iodine solution gives a brown flocculent ppt. which coagulates to a dark green mass on shaking. |
| 152 | 1 drop of ferric chloride solution added to saturated aqueous solution gives a transient violet-blue colour; with more ferric chloride the solution becomes cloudy, the colour changing through greyish-green to brown. |
| 153 | Ferric chloride solution added to a dilute aqueous solution gives a transient bluish colour. Bromine water gives a pale yellow flocculent ppt. |
| 154 | Reactions characteristic of saturated aliphatic hydrocarbon. |

| No. | SPECIAL TESTS |
|-----|---|
| 155 | Heavy, inflammable gas; mixtures with oxygen or air are explosive. |
| 156 | Specific rotation in 1% <i>w/v</i> sol. in dehydrated alcohol, +175° to 185°. |
| 157 | Specific rotation of well-boiled 10% aqueous solution about +52°. Reduces silver nitrate solution on warming. In addition to Fehling's, Barfoed's reagent (warm) is also reduced (distinction from dextrin and maltose). Sodium, calcium and barium oxides form saccharates soluble in water. Ferments with yeast. |
| 158 | Gives yellowish-red with sulphuric acid and a little nitric acid darkening on warming. From acid solutions is pptd. by caustic alkalis, ammonia and ammonium carbonate, re-dissolved by the first in excess. Does not reduce iodates (distinction from morphine). <i>See also</i> the hydrochloride. |
| 159 | Dissolve 0.05 g. in 5 ml. water; add 3 drops 5% ferric chloride solution; no blue colour (distinction from morphine). Nitric acid dissolves with yellow colour changing to blue on warming and becoming yellow again on cooling. Solution in conc. sulphuric acid, warmed, cooled, diluted with water and treated with potassium ferricyanide solution containing a trace of ferric chloride gives deep blue colour. Morphine, ethyl-morphine and codeine do not yield this reaction. |
| 160 | Ppt. with proteins. Soluble in alcohol, ether and cottonseed oil, but decomposes them. Readily soluble in chloroform and eucalyptus oil without evident change. Dissolves in solutions of fixed alkalis forming the soluble monochloramine. Strong oxidising agent liberating iodine from potassium iodide. Gives no ppt. with mercuric chloride (<i>cf.</i> chloramine). |
| 161 | Colourless liquid with characteristic odour. |
| 162 | Mono-nitro derivative has m.p. 55°. |
| 163 | 1 mg. in 1 ml. glacial acetic acid containing trace of ferric chloride layered on to sulphuric acid gives reddish band. Usually adjusted to standard strength by admixture with lactose. |
| 164 | Dissolves in cold hydrochloric acid giving colourless solution which becomes brown on warming. To 0.1 mg. in Petit's liquor add 2 ml. of acetic acid and 1 drop of ferric chloride solution, and layer on to sulphuric acid; a brown ring, blue-green above, is produced. |
| 165 | Specific rotation in 2% <i>v/v</i> sol. in pyridine (Hg light) +13.5 to 13.7. 1 ml. of 0.1% sol. in glacial acetic acid containing 0.01% FeCl ₃ with layer of conc. H ₂ SO ₄ gives brown ring and the acetic acid layer acquires an indigo colour. |
| 166 | Usually in aqueous solution, containing about 35% of hygroscopic diethanolamine salt of diiodine and about 17% <i>v/v</i> of iodine. |

| No. | SPECIAL TESTS. |
|-----|---|
| 167 | Heated with H_2SO_4 until brown and then with excess of NaOH , ammonia is evolved. |
| 168 | 0.0005 g. in 5 ml. water gives white ppt. with silver nitrate, a violet ppt. with cobalt nitrate and a white ppt. on warming with calcium chloride (distinction from sodium cacodylate). |
| 169 | Gives yellow or red solution in dilute NaOH with intense green fluorescence. |
| 170 | Sulphur is absent (distinction from saccharin). |
| 171 | With Froehde's reagent, first green then brown colour. Mandelin's reagent gives blue. A solution of about 0.01 g. in 5 ml. of melted phenol becomes crimson, changing to scarlet on adding a few drops of sulphuric acid. |
| 172 | Sulphomolybdic acid gives green colour with the hydrochloride or in presence of trace of chloride. 0.0002 g., e.g. in Tinct. Ipecac., gives yellow with hydrochloric acid and hydrogen peroxide. |
| 173 | Gives reactions of emetine and chlorides. Sulphomolybdic acid gives green colour. |
| 174 | Gives reactions for bismuth and iodine. Quickly loses its red colour on shaking with sodium bicarbonate and (more slowly) with 0.2% hydrochloric acid. |
| 175 | 0.01 g. in 1 ml. water with 0.1 ml. aqueous solution of copper sulphate and 1 ml. sodium hydroxide gives violet colour; on shaking mixture with ether, latter becomes purple and aqueous solution blue. Gives the hydrochloride on standing in contact with chloroform and evaporating. 0.01 g. in 1 ml. water with 1 ml. potassium ferricyanide solution and 1 ml. potassium hydroxide gives benzaldehyde odour. |
| 176 | Gives reaction for hydrochloride, and with copper sulphate reacts as ephedrine. |
| 177 | The dilute aqueous solution gives a blue colour with solution of dimethylaminobenzaldehyde. A purple colour is produced on adding 2 drops of sulphuric acid to 1 ml. of a 0.1% solution in glacial acetic acid containing a trace of ferric chloride. Crystals may contain solvent of crystallisation. |
| 178 | Gives reactions of ergometrine and tartaric acid. |
| 179 | Gives the same reactions as ergometrine. |
| 180 | Gives the same reactions as ergometrine. The acid radicle can be determined by dissolving in methyl alcohol, diluting and titrating with N/10 potassium hydroxide using phenolphthalein. |
| 181 | Usually occurs mixed with lactose from which it can be separated by extraction with alcohol. The residue obtained on evaporating the alcohol explodes on percussion. |

| 194 | Guaiacol Carbonate | C,H,O | 85-88 | — | — | Insoluble | About 200 |

| No. | SPECIAL TESTS |
|-----|---|
| 182 | Characteristic fragrant odour. Yields ethyl alcohol and acetic acid when hydrolysed. |
| 183 | A trace boiled with H_2O gives reddish-violet solution with 1 drop of ferric chloride changing to brown on adding further 2 drops. Mercuric nitrate to boiling solution gives ppt. and red supernatant liquid. |
| 184 | Gives phthalic acid and ethyl alcohol on hydrolysis. |
| 185 | Does not give blue colour with ferric chloride or reduce iodates directly. 0.01 g. dissolved in 10 ml. sulphuric acid after liberation of the hydrochloric acid, gives a clear solution, which on adding a drop of ferric chloride solution and warming turns violet or blue, changing to red on adding 2 to 3 drops of nitric acid. The free base is less soluble in ammonia than codeine. Such solution reprecipitates the base in crystals melting at 93° . |
| 186 | 1 ml. in a freezing mixture with equal volume of phosphoric acid added gradually gives a white crystalline mass of eucalyptol phosphate. If warm water is then added eucalyptol will separate. Agitated with strong solution of iodine in potassium iodide a pasty mass is produced in which green lustrous crystals are formed. |
| 187 | Bulky yellow ppt. on adding sodium salicylate to aqueous solution. No effervescence with sodium bicarbonate (<i>cf.</i> acriflavine). No ppt. with solution of formaldehyde (<i>cf.</i> proflavine). |
| 188 | Unmistakeable fluorescence in solution. Colour discharged by acid. Heated with zinc dust and sodium hydroxide reduced to colourless fluorescin. |
| 189 | Combines with ammonia. Reduces ammoniacal silver nitrate solution (mirror). Responds to Schiff's reagent. <i>See also</i> Milk Tests, Urine Tests, and Paraformaldehyde. |
| 190 | Is decolorised by zinc and hydrochloric acid also by sulphurous acid. For detection of minute quantities, as in urine, extract with acetic ether or amyl alcohol. The colour in these disappears on adding ammonia or hydrochloric acid if fuchsine present. |
| 191 | 0.001 g. gives green colour with conc. nitric acid. 0.001 g. with sulphuric acid and potassium dichromate gives reddish-violet turning green. |
| 192 | Occurs in crystalline form, or as a liquid. Characteristic odour and taste. An alcoholic solution with ferric chloride gives emerald-green changing to blue and then brown. Gives yellow and not red-brown on shaking with 10 vols. of sulphuric acid (distinction from creosote). |
| 193 | When hydrolysed gives reactions for guaiacol and benzoic acid. |
| 194 | 0.01 g. gives guaiacol and potassium carbonate on hydrolysis with alcoholic potash. |

| No. | SPECIAL TESTS |
|-----|--|
| 195 | When hydrolysed gives reactions for guaiacol and cinnamic acid. |
| 196 | Boiled with dilute acids gives formaldehyde and ammonium salt. Gives ppt. with mercuric chloride solution becoming crystalline on standing. |
| 197 | Dissolves in aqueous alkali hydroxides. Heat with aq. Na_2CO_3 on water-bath with alcoholic sol. of nitrobenzyl chloride for 30 minutes and let stand 1 hour; wash ppt. with dilute NaOH and recryst. from light petroleum; the m.p. of product is 116° – 117° . |
| 198 | Sol. in H_2O gives ppt. of hexobarbitone on adding acid. |
| 199 | Paraffin odour on heating. Sulphuric acid cold dissolves, hot chars and sulphur dioxide is evolved. Nitric acid gives violent reaction. Trace of ferric chloride added to alcoholic solution gives green colour. |
| 200 | Gives Pauly's reaction—a rose-pink coloration is obtained on adding sodium <i>p</i> -diazobenzenesulphonate to 1 in 10,000 aqueous solution. |
| 201 | An alkaline solution gives a deep red colour when mixed with an aqueous solution of sulphanilic acid containing a trace of hydrochloric acid and of sodium nitrite. The picrolonate obtained by mixing a hot solution of histamine acid phosphate with a hot alcoholic solution of picrolonic acid, after washing and drying has m.p. 266° to 267° . |
| 202 | Alkaloidal base, obtained by adding ammonia to aqueous solution, shaking out with chloroform and evaporating solvent, melts at about 98° and when warmed with 2% solution of mercuric chloride in alcohol (60%) gives yellow ppt. becoming brick-red. Does not react to Vitali's test—0.0001 g. gives yellow instead of violet given by atropine (<i>q.v.</i>). Does not ppt. with tannic acid or platinic chloride after adding hydrochloric acid. |
| 203 | Froehde's reagent gives green to brown colour. Sulphovanadic acid gives orange-red. Sulphuric acid with trace of molybdic acid gives green colour changing to brown. Sulphuric acid with trace of potassium dichromate gives light green colour changing to brown. |
| 204 | Aqueous solution acidified with sulphuric acid has blue fluorescence. With Nessler's reagent gives black ppt. of mercury. |
| 205 | Response to Vitali's reaction very similar to that of atropine (<i>q.v.</i>). Gold chloride compound obtained by dissolving separated base in hydrochloric acid, adding solution of auric chloride and recrystallising from water, has m.p. of 198° to 200° . |
| 206 | Response to Vitali's reaction very similar to that of atropine (<i>q.v.</i>). Gold salt (recrystallised from hot water) is in golden shining leaflets, m.p. 165° ; solutions reduce in the light. A 1 in 20 solution does not ppt. with platinic chloride solution (distinction from most alkaloids). |

|-----|--|
| 207 | Purple vapours on heating in test-tube. Colour disappears on treatment with alkaline reducing agents, <i>e.g.</i> , zinc and sodium hydroxide. |
| 208 | Ash contains sodium sulphate. Diazo test gives green colour. Colour of aqueous solution destroyed by nitric acid or bromine water, or by zinc and sodium hydroxide. |
| 209 | Readily soluble in sodium iodide solution. |
| 210 | Iodine is pptd. on adding nitric acid to a solution in warm alcoholic potassium hydroxide. |
| 211 | Cream ppt. with hydrochloric acid which re-dissolves in excess of sodium hydroxide solution with return of blue colour which subsequently disappears. Fused with sodium hydroxide, dissolved in nitric acid and treated with silver nitrate a yellow ppt. is obtained. |
| 212 | Warmed with zinc and sodium hydroxide, fumes of pyrrole are given off and impart a red colour to pine wood (<i>e.g.</i> a match) soaked in hydrochloric acid. Alcoholic solution gives a red colour with nitric acid. |
| 213 | Contains 50.5 to 52.5% of iodine and 9.2 to 9.4% of sodium. Addition of acid gives ppt. of the acid which melts with decomposition at about 174°. |
| 214 | Loses water at 130° and becomes yellow at 160°. Reduces Fehling's solution on heating. Becomes brown on heating with alkalis. Osazone separates only on cooling after prolonged heating and has m.p. 200° (decomp.). |
| 215 | Reduces bismuth salts in alkaline solution. On warming with alkali hydroxide the solution turns brown (as also dextrose). Fermentable directly but more slowly than dextrose. Combines with calcium hydroxide, forming insoluble gelatinous salt. Specific rotation of well-boiled 10% aqueous solution about -93° if pure. |
| 216 | Characteristic waxy appearance. Boiled with baryta gives glycerophosphoric acid, neurine, and a fatty acid (stearic, oleic, or palmitic). |
| 217 | Mercuric chloride to 10% sol. gives ppt., which, after recrystallising, melts at 177°-178°. |
| 218 | Hydrochloric acid ppts. aspirin; filtrate gives reactions for lithium. After hydrolysis gives reactions of salicylic acid. |
| 219 | Hydrochloric acid precipitates aspirin; filtrate gives reactions for magnesium. After hydrolysis gives reactions for salicylic acid. |
| 220 | Its solubility in amyl alcohol distinguishes it from methyl green and its allies. Aqueous solution becomes red on acidifying with hydrochloric acid. Colour base is pptd. on addition of sodium hydroxide and when recrystallised from benzene has m.p. of about 132°. |

|-----|---|
| 221 | Reduces Fehling's solution. Osazone separates on cooling after prolonged heating and has m.p. of 206°. |
| 222 | Explodes at 120°. |
| 223 | Turns light brown and decomposes in sunlight. Treat 0.0005 g. in 5 ml. of alc. with 2 ml. of strong ammonia and a few drops of ethyl cyanoacetate; violet colour is produced changing to yellow on adding 5 ml. of 30% sodium hydroxide. |
| 224 | Heated with benzoic anhydride the benzoic ester is obtained, m.p. 54.5°. Synthetic menthol usually has a lower m.p. |
| 225 | Yellow, bitter, crystalline powder. Ammonia to aqueous solution gives yellow or orange ppt. which is soluble in ether. Dilute nitric acid and mercuric chloride solution give yellow-green fluorescence and yellow precipitate. |
| 226 | Yellow, bitter, crystalline powder. Gives reactions as for Mepacrine Hydrochloride. After fusion with Na_2CO_3 , residue gives reactions for sulphate. |
| 227 | Hydrochloric acid precipitates dibromohydroxymercurifluorescein. Heated with sulphuric acid and nitric acid, cooled and diluted with water gives a ppt. of mercuric sulphide with hydrogen sulphide. Fused with sodium hydroxide and dissolved in dilute nitric acid, gives a ppt. of silver bromide with silver nitrate. |
| 228 | Decomposed on heating into mercury and cyanogen. Hydrogen cyanide evolved when heated with dilute hydrochloric acid. |
| 229 | Not ionised in solution and does not give the usual reactions for mercury and cyanide. |
| 230 | Decomposed by strong mineral acids with precipitation of salicylic acid. |
| 231 | Aqueous solution gives with sodium hydroxide a yellowish-white ppt. reduced to metallic mercury on heating. Heated with zinc dust in excess, pyrrole is evolved and imparts a red colour to pinewood (e.g. a match) moistened with hydrochloric acid and held in the vapour. |
| 232 | When heated for 15 minutes under a reflux condenser with formic acid and water (1 : 1) and the liquid decanted and cooled, salicylaldehyde-O-acetic acid separates; after washing and drying <i>in vacuo</i> crystals have m.p. 119° to 121°. |
| 233 | Boiling range 130° to 200° at 3 mm. pressure; R.I. at 55° about 1.66. Dissolved in H_2SO_4 gives intense violet-blue colour which disappears on dilution. Contains about 23 to 26% of sulphur. |
| 234 | Heated with dilute sulphuric acid, acetaldehyde is obtained. |

| No. | SPECIAL TESTS |
|-----|---|
| 235 | A trace boiled with H_2O gives reddish-violet solution with 1 drop of ferric chloride changing to brown on adding further 2 drops. Mercuric nitrate to boiling solution gives ppt. and red supernatant liquid. |
| 236 | Characteristic odour. Gives violet colour with ferric chloride. When hydrolysed with alkali and the acid precipitated by adding hydrochloric acid, salicylic acid, m.p. 158° , is obtained. |
| 237 | Is decomposed on heating with sodium hydroxide or sulphuric acid into acetic acid and monomethylaniline. The latter gives with nitrous acid a nitroso compound insoluble in sodium hydroxide. Soluble in chloroform (1 in 2)—distinction from acetanilide and phenacetin. |
| 238 | Aqueous solution decolorised on warming with zinc dust and acetic acid, colour reappearing if solution is filtered and exposed to air. Aqueous solution with potassium iodide solution gives deep blue flocculent ppt. Aqueous solution with slightly acid solution of potassium dichromate gives bluish-violet ppt., the liquid becoming red-violet but the blue is restored with sulphurous acid. Nitrous acid converts to methylene green. |
| 239 | 0.1 g., heated with 2 ml. conc. sulphuric acid, gives a brown colour changing to green and then blue, and on adding alcohol a blue turning to wine-red. |
| 240 | Heated with anhydrous sodium acetate, hydrogen sulphide is evolved. Heated with charcoal gives odour of mercaptan. |
| 241 | Sprinkled on nitric acid gives orange-red colour. Heated with sulphuric acid on a water-bath for 15 minutes, cooled and treated with nitric acid gives blood-red colour. Froehde's reagent gives reddish-violet, changing to slate blue. Liberates iodine from iodic acid. Gives blue ppt. with ferric chloride and potassium ferricyanide solution (freshly prepared). |
| 242 | Gives reactions of morphine and hydrochloride. |
| 243 | Characteristic odour. The picrate, precipitated from alcoholic solution, has m.p. 150° . |
| 244 | Dissolves in conc. sulphuric acid giving greenish-yellow solution becoming red on warming and violet on boiling. Stirred with conc. sulphuric acid and a crystal of potassium dichromate an intense red coloration is produced. |
| 245 | On adding hydrochloric acid to aqueous solution, a yellow ppt. of free acid is produced; if mixture is heated, sulphur dioxide is evolved. On distilling the aqueous solution acidified with phosphoric acid, the distillate contains formaldehyde. |
| 246 | Excess of bromine water added to the solution in sulphuric acid gives a yellow ppt. Ferric chloride solution added to the 1% solution in alcohol gives a yellow coloration (cinchophen gives a reddish-brown). |
| 247 | Characteristic odour. Has properties of a tertiary amine. The picrate has m.p. 219° . A rose-red coloration is produced on adding 1 drop of formaldehyde solution followed by 1 drop of nitric acid. |

| No. | SPECIAL TESTS |
|-----|---|
| 248 | Oily liquid or crystalline solid. R.I. at 20°, about 1.525. The 25% solution gives ppt. with alkaline potassio-mercuric iodide or mercuric chloride, and brownish flocculent ppt. with tannic acid, but no ppt. with potassio-mercuric iodide or picric acid. |
| 249 | Detection of traces: distil with a little sulphuric acid in steam, shake distillate with chloroform, convert oily drops into aniline by reduction with zinc and sulphuric acid. |
| 250 | Anæsthetic (surface, spinal, etc.), formerly known as Percaine. Gives reactions for chlorides unless in form of free base. |
| 251 | Specific rotation of 1% solution in dioxan +75° to 82°. Monobenzoate melts at about 190° and dipropionate at about 103°. |
| 252 | Specific rotation of 1% solution in dioxan +58° to 61°. Alkalis liberate oestradiol, which melts at 175°-178°. |
| 253 | Specific rotation of 1% solution in dioxan +53° to 63°. |
| 254 | Specific rotation of 1% solution in dioxan +157° to 167°. Monomethyl derivative melts at about 165°; monoacetate, about 125°; semicarbazone, about 258°; benzoate, 218° to 222°. |
| 255 | 5% aqueous solution with 10% sodium nitrite solution acidified with hydrochloric acid gives yellowish-white and on exposure to air an orange ppt. darkening to red. Distinguished from amydracaine, amylocaine, benzamine, cocaine, phenacaine, procaine and tropacocaine by Froehde's reagent which gives a faint violet tinge but nil with others except tropacocaine which gives slight green. Gives no ppt. with solution of iodine (distinction from benzocaine). |
| 256 | 1 ml. of 1% aqueous solution layered on to conc. sulphuric acid acquires a dirty green coloration and the acid is coloured pink to red. |
| 257 | Yellow, or orange-yellow, bitter powder. Formaldehyde added to 1% mixture with sulphuric acid gives green colour slowly. Add HCl to 4% solution in acetone, filter off white ppt., after adding water and then add powdered sodium iodate; violet colour appears suddenly after about 2 minutes. |
| 258 | 0.01 g. with 5 ml. of sulphuric acid gives colourless solution becoming rose-red at 110° and darkening to violet at 200°, the colour being discharged on adding water. Gives rose-red colour with sulphuric acid containing solution of formaldehyde. Aqueous solution of potassium ferricyanide gives with a faintly acid solution a yellow ppt. which when washed and dried dissolves in sulphuric acid containing solution of formaldehyde, giving a pale blue colour darkening to bluish-violet. |
| 259 | Formaldehyde odour on heating. Distillate in water reduces silver nitrate (forming mirror). Responds to Schiff's test (sulphurous fuchsin solution). 0.5% sodium nitroprusside solution gives red coloration changing to purple on acidifying with acetic acid. Nessler's reagent gives a reddish ppt. which gradually changes to grey. If to 5 ml. sulphuric acid in which 0.02 g. salicylic acid is dissolved, 2 drops of formaldehyde (37%) be added and the liquid gently warmed, a permanent red colour forms. In general, gives the reactions of aldehydes. |

| No. | SPECIAL TESTS |
|-----|---|
| 260 | More soluble in cold water than hot—saturated aqueous solution becomes turbid on warming. Gives mirror with ammoniacal silver nitrate on warming. Gives reactions of aldehydes, but does not add ammonia or sodium bisulphite. Warmed with sulphuric acid it is converted into acetaldehyde. |
| 261 | Neutral complex carbohydrate reducing Fehling's solution. Contains about 11.8% of methyl alcohol as methoxyester. Yields calcium pectate after hydrolysis containing 7.62% of calcium. |
| 262 | A liquid alkaloid giving a strongly alkaline solution. On reduction it yields coniine. Hydrochloride has m.p. 143° to 144°; hydrobromide has m.p. 140°. |
| 263 | Gives deep blue ppt. with cobalt or copper sulphate. The base absorbs oxygen from the air, resinifying. Pelletierine with sulphuric or selenious acid gives a red colour, deepening on heating and changing to green (distinction from arecoline). |
| 264 | Isomeric with amylethylbarbitone soluble; contains methylbutyl group instead of iso-amyl. Gives general reactions of malonylureas. |
| 265 | Soluble in solutions of alkali hydroxides. Ammonia and methylamine evolved when heated with alkali hydroxide. |
| 266 | Yellow waxy ppt. with sodium nitrite and hydrochloric acid. |
| 267 | Potassium dichromate in hydrochloric acid solution gives red colour. 1 ml. of a solution of 0.2 g. in 2 ml. hydrochloric acid (25%) boiled cooled and filtered gives reddish violet on adding 5 drops chlorine water and violet changing to red on adding 1 drop potassium dichromate solution. Colour reaction (Carletti): moisten a small quantity of phenacetin in a dish with acetaldehyde and 2 to 3 ml. sulphuric acid; on stirring with a rod the acid turns red (increased by warming). Sensitive to 0.001 g. |
| 268 | Aqueous solution with trace of sodium nitrite and dilute sulphuric acid gives green colour. 1 to 2 ml. of 0.1% aqueous solution with 1 drop of ferric chloride solution gives deep red colour changed to light yellow by dilute sulphuric acid. Aqueous solution gives with an equal volume of nitric acid a yellow solution changing to crimson on warming. Tannin gives a white ppt. with 1% solution. |
| 269 | TO DISTINGUISH FROM BARBITONE. Dissolve 0.1 g. in 1 ml. sulphuric acid and add trace of sodium nitrite—orange colour with phenobarbitone, none with barbitone. Heat with sodium hydroxide, acidify with sulphuric acid—carbon dioxide evolved with sweet acetic odour. Gives ppt. with Millon's reagent, with or without nitric acid. Mix 0.1 g. with 0.5 g. potassium nitrate and 2 ml. sulphuric acid. Heat on boiling water-bath 10 minutes and pour into 10 ml. cold water. Reduce pptd. nitro-compound with Zn and decant solution. Cool, acidify, add aqueous solution of 0.1 g. potassium nitrite and add to a solution of β -naphthol in sodium hydroxide—blood-red colour distinguishes barbituric acid with phenyl group. |

| No. | SPECIAL TESTS |
|-----|--|
| 270 | Gives reactions of sodium and yields ppt. of phenobarbitone on acidifying the aqueous solution. |
| 271 | 1 ml. of solution of 0.2 g. in 2 ml. of hydrochloric acid (25%), boiled, cooled and filtered, with 5 drops of fresh chlorine water, gives reddish-violet colour. 0.1 g. boiled with 2 ml. 33% sodium hydroxide and then 2 drops of chloroform added gives phenyl isocyanide odour and black drops on surface. |
| 272 | To 0.001 g. in 10 ml. water add 1 drop of 10% sodium nitrite solution and pour on to sulphuric acid. A coloured zone—red above, green below—appears at the junction. Bleaching powder to an aqueous solution gives violet colour. |
| 273 | Red colour with caustic alkalis disappearing with acids. Silver nitrate gives a violet ppt. |
| 274 | Acidified solution gives coloured ppt. with solution of sodium nitrite. |
| 275 | A trace dissolved in water gives with ferric chlorid a green colour rapidly becoming brown. <i>p</i> -phenylene diamine give ^c with a reagent containing cobalt nitrate 5 g. and ammonium thiocyanate 1 g. in 10 units of water, brown spherical crystals; <i>p</i> -toluylene ^a diamine, 1 : 2 : 5-diaminoanisole and <i>p</i> -amino-diphenylamine do not react. |
| 276 | Reduces Fehling's solution in cold. 1 in 50,000 stated to be detected by following test:—To solution add a few drops of aqueous trimethylamine and several drops of sodium nitroprusside. A blue-green colour is produced becoming more marked on addition of potassium hydroxide and red if heated afterwards. |
| 277 | Sodium sulphide to cold solution gives white ppt., changing to black on boiling. Heated with zinc, reduced iron and NaOH solution, ammonia is evolved. Heated with iodine solution and then decolorised with sodium thiosulphate, gives aromatic odour. |
| 278 | Acidify solution with HCl; the white ppt. of phenytoin after washing and drying melts at 295°. |
| 279 | Solutions have avidity for ammonia. In taking up 10% it turns red and melts to a colourless mass. Mix 0.1 g. with a crystal of vanillin and 1 drop of hydrochloric acid, on warming a red colour is obtained. |
| 280 | See under physostigmine salicylate. |
| 281 | Warmed with a few drops of ammonia a yellowish-red colour is produced, and on evaporation a blue residue giving a blue alcoholic solution. On adding acetic acid the solution is blue by transmitted light with a red fluorescence intensified on dilution with water. |
| 282 | Mixed with thrice its weight of potassium nitrate, moistened with sulphuric acid and then sodium hydroxide in excess added, a red colour is produced (Langley's reaction). On the addition of 1 drop 20% anisaldehyde in dehydrated alcohol to a trace of picrotoxin moistened with sulphuric acid, a violet colour is produced. |

|-----|---|
| 283 | Hydrochloride has m.p. 204° to 205°; aurichloride, 117° to 130° and picrate 147°. |
| 284 | To 2 to 3 ml. of 0.2% aqueous solution acidified with 1 or 2 drops dilute sulphuric acid add equal volume of hydrogen peroxide solution and pour layer of benzene on to the mixture; add 1 or 2 drops of potassium dichromate solution and shake. Benzene layer becomes coloured bluish-violet, the aqueous layer remaining yellow (distinction from other alkaloids). |
| 285 | Dissolves uric acid forming the neutral urate. Gives white ppt. with Nessler's reagent. Piperazine phosphate forms 4-sided tabular crystals. |
| 286 | Alkalis convert into gelatinous acid which loses water, giving a substance melting at 227°. |
| 287 | 0.00005 g. in 5 ml. acidified water gives orange colour with hydrogen sulphide. Larger amount gives ppt. soluble in ammonium sulphide or potassium hydroxide. With Marsh Test—black mirror insoluble in sodium hypochlorite solution. With lime water—white ppt. soluble, when freshly pptd., in acetic acid and ammonium chloride. |
| 288 | Aqueous solution gives intense violet-blue colour with ferric chloride, the colour disappearing on addition of ammonia or strong solutions of alkali sulphates or chlorides. Sulphuric acid and a trace of formaldehyde added to the aqueous solution give a reddish-violet colour. Nitric acid added to the aqueous solution produces a deep red colour on warming; white crystals separate on cooling. |
| 289 | Diazo test gives slight brown-red. Aqueous solution with ferric chloride gives bright green colour. Bromine water gives ppt. of dibromohydroxyquinoline. Gives ppt. with salts of some metals. |
| 290 | Anhydrous base recrystallised from light petroleum has m.p. 58° to 60°. Aqueous solution with trace of sodium nitrite and hydrochloric acid, added to solution of β -naphthol in dilute sodium hydroxide gives scarlet ppt. Slightly acid solution immediately decolorises permanganate solution (distinction from cocaine). Aqueous solution with aqueous solutions of sodium nitrite and sodium carbonate containing 0.5% potassium guaiacolsulphonate, acidified with hydrochloric acid, gives a red to yellow colour, varying with the concentration. |
| 291 | Solutions are similar to those of acriflavine. Gives reactions of sulphates. Aqueous solution reduces permanganate readily and gives ppt. with solution of formaldehyde. |
| 292 | The dioxime has melting-point of 243°. Specific rotation, 1% solution in dehydrated alcohol, +183° to 194° |
| 293 | After heating with sodium hydroxide and acidifying with sulphuric acid, carbon dioxide is evolved and a pungent vapour with odour resembling menthol. Saturated solution gives white ppt. with Millon's. No colour with Nessler's reagent except on fusing with potassium hydroxide. |

|-----|--|
| 294 | A trace boiled with H_2O gives reddish-violet solution with 1 drop of ferric chloride changing to brown on adding further 2 drops. |
| 295 | Alkaline to litmus, but does not affect phenolphthalein. Forms salts readily; with picric acid forms yellow crystalline picrate. |
| 296 | In presence of alkali it rapidly absorbs oxygen, giving a dark-coloured solution. |
| 297 | Slightly acid solution treated with bromine and then ammonia gives green coloration. |
| 298 | Gives a white ppt. gradually on adding silver nitrate solution to saturated solution. |
| 299 | Dissolves with blue fluorescence in sulphuric acid, acetic acid or tartaric acid. White ppt. with ammonia soluble in excess and in ether. 1 ml. of 1% quinine (dissolved with dilute acid) with 2 to 3 ml. bromine water followed by 1 ml. dilute solution of ammonia gives emerald-green colour (thalleoquin test). Is distinctive for quinine and shows less than 0.0001 g. Belladonna, colchicum, conium, gelsemium, ipecacuanha, opium, nuxvomica do not inhibit the reaction. Use dilute solutions. |
| 300 | <i>See reactions for quinine.</i> Odour of acetic acid is produced on heating with dilute acid. |
| 301 | <i>See reactions for quinine.</i> Aqueous solution is acid to litmus but not to congo red, and is fluorescent. |
| 302 | <i>See reactions for quinine.</i> Aqueous solution is acid to litmus but not to congo red. It fluoresces on the addition of dilute sulphuric acid. |
| 303 | Solutions in dilute acid give reactions of quinine. On warming with sodium hydroxide and iodine solution, iodoform is pptd. |
| 304 | <i>See reactions for quinine.</i> Aqueous solution is neutral or very slightly alkaline to litmus and is not fluorescent. |
| 305 | Bright red powder. |
| 306 | <i>See reactions for quinine.</i> Gives violet coloration with ferric chloride. |
| 307 | <i>See reactions for quinine.</i> |

|-----|--|
| 308 | With methyl iodide it reacts to form a methiodide, m.p. 134°. The picrate has m.p. 203° and the hydrochloride 93°. Gives amorphous ppt. with Mayer's reagent which forms yellow needles on adding hydrochloric acid. |
| 309 | On heating 0.05 g. with 0.1 g. tartaric acid and 10 drops conc. sulphuric acid, carmine liquid forms which is yellow on diluting with water. Not pptd. by neutral lead acetate (distinction from catechol). Bluish-violet with ferric chloride changing to yellow on adding ammonia (distinction from catechol and quinol). Resorcinol and phloroglucinol are the only ordinary phenolic compounds giving coloured ppt. immediately in the cold when 2 ml. of 40% formaldehyde and 3 ml. conc. hydrochloric acid are added to a solution of 0.1 g. in 3 ml. 95% alcohol. |
| 310 | Gives reactions of resorcinol and acetic acid. |
| 311 | Forms stable crystalline compounds with carbon tetrachloride (rotenone-carbon tetrachloride), acetone, dichloroacetic acid, etc. From carbon tetrachloride complex pure rotenone is separated by triturating with dehydrated alcohol and then crystallising from hot dehydrated alcohol. Optical rotation of 4% solution in benzene at 20° in 10 cm. tube is -9.04. |
| 312 | Dissolved in 25% potassium hydroxide solution and bromine water added until yellow, bromine substitution body is thrown out. 0.0001 g. heated with 1 mg. resorcinol and 1 drop sulphuric acid gives yellow then dark green. After cooling dissolve in water and add 1 or 2 drops 33% sodium hydroxide solution—intense fluorescence. |
| 313 | Gives reactions of saccharin and leaves residue of sodium sulphate on ignition. |
| 314 | Gives on alkaline hydrolysis reactions of salicylic acid, and the liquid reduces Fehling's, smells of methyl salicylate and burnt sugar, and turns yellow. |
| 315 | Heated with potassium dichromate and dilute sulphuric acid gives salicylic aldehyde (meadowsweet). Dissolves in hydrochloric acid, and on boiling throws out resin (saliretin). Gives blood-red colour with conc. sulphuric acid. |
| 316 | Yields salicylic acid on hydrolysis. |
| 317 | Alcoholic solution ppts. with bromine. Violet with ferric chloride in alcoholic solution. Test for phenol and salicylic acid after heating with alcoholic potassium hydroxide. |
| 318 | Warmed on water-bath with 50% sulphuric acid and a trace of ferric chloride, yellow colour forms, changing through red to violet, or a blood-red can be extracted by amyl alcohol. A crystal warmed with ethyl nitrite solution and a few drops of potassium hydroxide gives a rose-red, with alcoholic potassium hydroxide alone a violet-red colour is obtained. |

| No. | SPECIAL TESTS |
|-----|---|
| 319 | Gives a bluish-green solution in sulphuric acid and the solution gives a red ppt. on dilution. |
| 320 | Solution gives no ppt. with ammonium sulphide but becomes black-brown. To 2 ml. 5% aqueous solution add 1 drop of acetic acid; a white ppt. is produced soluble in excess. 10 ml. 1% solution with 5 ml. sodium hydroxide becomes violet in a few minutes on adding 2 ml. 2% copper sulphate solution. |
| 321 | Contains about 20% Ag. |
| 322 | 0.001 g. in 5 ml. water reduces permanganate and gold chloride. Ferrous sulphate solution gives olive-green ppt. Sodium hypobromite gives bluish-red colour. |
| 323 | Responds to tests given for potassium antimonytartrate and also gives sodium flame. |
| 324 | Few drops of aqueous solution with 2 ml. hypophosphorous acid develops garlic odour of cacodyl in a short time. Aqueous solution with mercuric nitrate solution gives white ppt. becoming yellow. |
| 325 | Solid compound is sodium salt of β -glycerophosphoric acid. The salt of the α -acid occurs usually as a 50% solution. An aqueous solution of the former does not reduce cold periodic acid. On incineration pyrophosphate is formed. Lead acetate precipitates but not magnesia mixture. Cold ammonium molybdate precipitates either on standing or heating. |
| 326 | Official substance is viscous liquid containing 68 to 72% of $\text{CH}_3\text{-CHOH-COONa}$. Gives characteristic reactions of lactates. |
| 327 | Gives reactions of sodium and mandelic acid. |
| 328 | Dilute solution does not give yellowish brown with uranium nitrate solution (distinction from salicylate). Incineration gives about 30% Na_2SO_4 . |
| 329 | <i>See</i> salicylic acid. |
| 330 | Taurocholic acid forms shining hygroscopic bitter needles easily soluble in water and alcohol. Solutions dextrorotatory. On heating at 100° or boiling with alkalis or acids, decomposes into cholic acid, $\text{C}_{24}\text{H}_{46}\text{O}_8$, taurine, $\text{C}_2\text{H}_7\text{NO}_2\text{S}$, and glycerin. To an aqueous solution add a crystal of sucrose and conc. sulphuric acid drop by drop; a brownish-red colour is produced changing through violet to blue on keeping (Pettenkofer's bile acid test). |
| 331 | Fused with sodium hydroxide, dissolved in nitric acid and treated with silver nitrate—yellow ppt. of silver bromide. On acidifying aqueous solution light buff ppt. of the phthalein is produced. |

| No. | SPECIAL TESTS |
|-----|---|
| 332 | White ppt. with cadmium iodide. Sodium phosphomolybdate gives white ppt. soluble on heating. Ammonium sulphide forms orange colour. To 0.1 g. add 25 ml. ether and a few drops of ammonia followed by a 2% ethereal solution of iodine until the liquid acquires a dark red-brown colour; a greenish-brown crystalline ppt. forms on the sides of the bottle. GRANT'S TEST:—A strip of filter paper moistened with the chloroform extract of the ammoniacal solution of the alkaloid is dried and exposed to bromine then to ammonia fumes. On finally warming, a bright pink colour forms. |
| 333 | The residue from fusion with KOH and KNO ₃ gives reactions for antimony, sodium and sulphates. Solution with ferric chloride gives bluish-green colour turning violet or cherry-red on adding NaHCO ₃ . 1% solution in dilute acetic acid decolorises iodine solution. Solution gives yellow colour with NaOH which disappears on adding acid. |
| 334 | Ultra-violet absorption in dehydrated alcohol at 240 m μ , calculated on dry substance, about 590. |
| 335 | S.V. about 290. Ultra-violet absorption in dehydrated alcohol at 240 m μ , calculated on dry substance, about 390. |
| 336 | Strophanthin, B.P. 1932, is adjusted to standard activity by admixture with lactose. The m.p. and solubility of unadjusted substance vary with the method of extraction. Aqueous solution is dextrorotatory. Dissolved in a cold mixture of sulphuric acid and water (4 : 1), an emerald-green colour is produced (distinction from ouabain). |
| 337 | Trace dissolved in sulphuric acid and a crystal of potassium dichromate moved through solution gives violet colour passing through red to yellow. Vitali's reaction (<i>see</i> Atropine) gives yellow passing to violet. Mandelin's reagent gives violet-blue changing to purple, and becoming red on dilution with water. Phosphomolybdic acid will show 0.0001 g., picric acid 0.00005 g., tannic acid 0.00004 g., mercuric potassium iodide 0.000006 g., potassium bismuth iodide 0.00002 g., platinic chloride only 0.001 g. and gold chloride 0.0001 g. |
| 338 | Gives reactions of strychnine and of hydrochloride. |
| 339 | Becomes brown when heated with conc. potassium hydroxide solution (dextrose becomes brown in the cold). Not directly fermentable—requires inversion by yeast or dilute acids. Does not form osazone or reduce Fehling's until hydrolysed. When a mixture of 1 ml. of saturated nickel ammonium sulphate solution, 1 ml. of sucrose solution and a few drops of sulphuric or hydrochloric acid is boiled, the green colour changes to yellow and then to red. 0.005 g. of sucrose responds, other sugars not interfering. Sucrose can be separated from a dry mixture with dextrose by extraction with hot ethyl acetate, sucrose being insoluble. |

| No. | SPECIAL TESTS |
|-----|---|
| 340 | Heated with sulphuric acid and ethyl alcohol, odour of ethyl acetate (distinction from sulphanilamide, sulphapyridine and sulphathiazole). Soluble in NaOH forming soluble sulphacetamide. |
| 341 | An intense violet-colour is produced when heated in a dry tube and ammonia and aniline are evolved. Solution of the diazo-compound gives an orange ppt. with β -naphthol solution. Add platonic chloride in 0.5N hydrochloric acid; warming produces light yellow convex lens-shaped crystal of the chloro-platinate. Then add warm, saturated sodium bromide; orange-yellow hexagonal prisms of the bromo-platinate are produced. Cold saturated picric acid precipitates large yellow needles or prisms. On warming with a neutral solution of picrolonic acid, sheaves or star-shaped clusters of light yellow needles or prisms are produced. |
| 342 | Gives brown colour heated in a dry tube and sulphur dioxide is evolved. Solution of 0.02 g. in 5 ml. of H_2O and 0.25 ml. of N/1 NaOH gives green ppt. with a few drops of copper sulphate. Soluble in NaOH forming soluble sulphapyridine. |
| 343 | Aqueous solution decolorises solution of iodine. 1 ml. of 10% aqueous solution mixed with 5 ml. of dilute hydrochloric acid gives a yellow ppt. in a few minutes and SO_2 is evolved on boiling the mixture but no ppt. is obtained on adding 1.5 ml. of dilute hydrochloric acid to a solution of 0.5 g. in 1.5 ml. of water (distinction from neoarsphenamine). On distilling the aqueous solution acidified with phosphoric acid, the distillate contains formaldehyde. The 10% aqueous solution does not decolorise an equal volume of 0.01% aqueous indigo carmine solution when the mixture is maintained at 50° for 5 minutes (distinction from neoarsphenamine). |
| 344 | Heated in a dry tube it melts, darkens and then evolves ammonia and odour of mercaptan. Solution of 0.02 g. in 5 ml. of H_2O and 0.25 ml. of N/1 NaOH gives greyish purple ppt. with a few drops of copper sulphate. Soluble in NaOH forming soluble sulphathiazole. |
| 345 | Fused with potassium hydroxide it becomes yellow then red, and on diluting with water, blue. On acidifying a transient violet is produced and sulphur pptd. Heated with charcoal, mercaptan is evolved. |
| 346 | Boil for 5 minutes with 50% H_2SO_4 , dilute with 9 volumes of water, cool, add trace of $NaNO_2$, and let stand 1 min., add urea, and after 2 minutes add a few drops of the mixture to a solution of α -naphthylamine buffered with sodium acetate and acetic acid. |
| 347 | On adding a few drops of conc. sulphuric acid to a hot solution the liquid becomes turbid and an odour of lilac is produced. |
| 348 | Strong odour of hyacinth and lilac. |
| 349 | Specific rotation in 1% solution in dioxan, $+104^\circ$ to 112° . Oxime melts at 222° to 223° , semi-carbazone at 225° , benzoate at 194° to 196° , and acetate at 140° to 141° . |

|-----|--|
| 350 | Specific rotation in 1% solution in dioxan, $+83^{\circ}$ to 90° . Hydrolysed to testosterone and propionic acid with alcoholic KOH, with ppt. of testosterone on dilution with water. |
| 351 | Odour resembles that of chloroform. |
| 352 | Odour resembles that of carbon tetrachloride. |
| 353 | Gives a blood-red coloration with sulphuric acid changing on warming to orange-yellow and eventually to olive green. |
| 354 | Gives murexide reaction (<i>see under Caffeine</i>). Ppts. silver theobromine on adding silver nitrate solution to a very dilute solution acidified with nitric acid. On adding bromine water to the solution in hydrochloric acid, boiling off bromine, and adding a trace of ferrous sulphate and a few drops of ammonia, a purple colour is produced. |
| 355 | Aqueous solution gives violet colour with ferric chloride. Theobromine is pptd. by dilute acids. |
| 356 | Gives murexide reaction. Aqueous solution 1 in 5 neutralised with dilute hydrochloric acid in presence of litmus solution gives white ppt. of theobromine. (A little alkali assists its solubility in water.) |
| 357 | On neutralising aqueous solution with hydrochloric acid, theobromine is pptd. On acidifying with acetic acid and adding ferric chloride, a purple colour is produced. |
| 358 | Gives murexide reaction. Distinguished from theobromine by giving a clear 4% solution in ammonia. |
| 359 | Has a slight ammoniacal odour. Theobromine is pptd. on acidifying the aqueous solution. |
| 360 | Gives reactions of theophylline and also of acetate (after removing the theophylline by neutralising and filtering). |
| 361 | Usually has a faint garlic odour. Heated with lead hydroxide, hydrogen sulphide is removed. |
| 362 | Usually has slight garlic odour. Sodium nitrite and hydrochloric acid give brown ppt. Yellow ppt. with lead acetate insoluble in dilute nitric acid but blackened by the conc. acid. |
| 363 | Characteristic odour. Dissolved in 1 ml. glacial acetic acid and treated with 0.3 ml. sulphuric acid and 1 ml. nitric acid, a bluish-green colour is produced. |
| 364 | Iodine separates on heating with sulphuric acid. |

|-----|---|
| 365 | When to a solution of a trace in alcohol 50%, prepared with the aid of 1 drop of hydrochloric acid, 1 drop of 20% aqueous sodium nitrite is added, a yellow colour is produced which deepens on boiling; on cooling and adding excess of ammonia the colour changes to red. |
| 366 | By treatment with fuming nitric acid and fuming sulphuric acid at room temperature the 2 : 4-dinitro derivative is obtained, m.p. 70°. |
| 367 | Decomposed on heating into dibromoacetaldehyde and hydrogen bromide. Is supplied as a solution in amylene hydrate. |
| 368 | Colourless, volatile, non-inflammable liquid. |
| 369 | Hydrochloric acid added to the alcoholic solution gives a white ppt. of the hydrochloride which after washing with alcohol and drying has m.p. 173° to 174°. |
| 370 | Gives additional compounds with polynuclear hydrocarbons, e.g. naphthalene picrate (m.p. 150°) is pptd. on cooling 0.1 g. naphthalene and 0.2 g. trinitrophenol in 4 ml. dehydrated alcohol. |
| 371 | Presence of arsenic shown by heating for 45 minutes at about the b.p. with sulphuric and fuming nitric acids, heating again with more nitric acid until no more brown fumes are evolved, then adding solid ammonium sulphate followed by dilute sulphuric acid, boiling with sulphurous acid and testing as usual with hydrogen sulphide. When boiled with sodium hydroxide, ammonia is evolved. Silver nitrate gives a white acicular ppt. |
| 372 | Bluish-grey giving violet colour in water. |
| 373 | Heated above m.p., ammonia is evolved and biuret formed which gives a reddish-violet colour when dissolved in water, made alkaline with sodium hydroxide and treated with 1 drop copper sulphate solution. Urea nitrate pptd. from strong solutions on addition of nitric acid. Decomposed by hypobromite with liberation of nitrogen. |
| 374 | Heated with potassium hydroxide it yields ammonia, potassium carbonate and alcohol. |
| 375 | Mixed with powdered sucrose and sulphuric acid it gives green colour turning blue. Heated with hydrochloric acid on water-bath a blood-red solution is obtained. M.p. is indefinite. |
| 376 | Slightly fluorescent and has characteristic odour. As supplied for anæsthetic purposes contains 3.5% of dehydrated alcohol and 0.01% of phenyl- α -naphthylamine. |
| 377 | A mixture of the <i>o</i> -, <i>m</i> -, and <i>p</i> -compounds, the respective b.p.'s being 142°, 139°, and 138°. Oxidation with alkaline permanganate gives respectively phthalic acid (m.p. 184° decomp.), isophthalic acid (sublimes at 300°), and terephthalic acid (sublimes at 300°). |
| 378 | Yellowish-green ppt. with potassium ferrocyanide insoluble in hydrochloric acid. Decolorises bromine water. |

HYDROGEN ION CONCENTRATION

Many inorganic and some organic substances when dissolved in solvents produce solutions which conduct electricity. The current is carried by ions which are produced by the dissociation of the dissolved substance. Thus a solution of sodium chloride in water contains positively charged sodium ions and negatively charged chlorine ions. Similarly acetic acid solution contains positively charged hydrogen ions and negatively charged acetate ions. The extent to which acetic acid, for example, is dissociated in solution into its ions is regulated by the concentration and the temperature, and on the degree of dissociation will depend the conductivity of the solution.

The equilibrium between undissociated molecule and ions produced by the dissociation is represented by the equation

It is governed by the law of Mass Action, and by applying that law the following relation may be deduced:—

$$\frac{[\text{CH}_3\text{COO}'] \times [\text{H}^{\cdot}]}{[\text{CH}_3\text{COOH}]} = K = \text{Dissociation Constant of the acid,}$$

where the square brackets indicate the concentration of the molecules or ions enclosed by the brackets.

Ordinary tap water, and even ordinary distilled water, will conduct electricity, but as both contain dissolved substances (salts and carbon dioxide in the case of tap water, and carbon dioxide in the case of distilled water) it is not possible to infer from this evidence that water is dissociated into ions. After very careful purification to remove all dissolved gases and other impurities pure water will still conduct electricity to a small extent, and this is due to the dissociation of water into positively charged hydrogen ions and negatively charged hydroxyl ions. The dissociation of water molecules into these ions, as represented by the equilibrium

is also governed by an expression deduced by applying the law of Mass Action:—

$$\frac{[\text{H}^{\cdot}] \times [\text{OH}']}{[\text{H}_2\text{O}]} = K = \text{Dissociation Constant of water.}$$

Since the extent of dissociation of water is small the amount of undissociated water will be very nearly the total amount of water considered and the value of the term $[\text{H}_2\text{O}]$ remains constant for all practical purposes.

$$\text{Hence } [\text{H}^{\cdot}] \times [\text{OH}'] = K \times [\text{H}_2\text{O}] = K_w.$$

K_w has a constant value at constant temperature and is termed

the ionic product of water. Its value is 55 times that of the dissociation constant of water. The ionic product, K_w , represents the extent of dissociation of water at a given temperature, and at 20° it has the value 10^{-14} when the values of $[H^+]$ and $[OH^-]$ are expressed in gram-ions per litre (1 gram-ion of hydroxyl representing 17 g. of hydroxyl ions). On dissociation, pure water will give rise to equal numbers of hydrogen ions, H^+ , and hydroxyl ions, OH^- , and at 20° a litre of pure water will contain 10^{-7} gram-ion of H^+ ($= 0.0000001$) and 10^{-7} gram-ion of OH^- .

If there is added to pure water a substance giving rise to hydrogen ions, say hydrochloric acid, the concentration of H^+ in the solution will momentarily increase to more than 10^{-7} gram-ion per litre. The value of $[H^+] \times [OH^-]$ is restored to its constant value of 10^{-14} by a reduction of $[OH^-]$ effected by combination of some of the OH^- with some of the added H^+ to form undissociated water molecules. The solution now contains more hydrogen ions than hydroxyl ions and is said to be acid in reaction.
